Sweet Peas Flowering Earlier.—A few years ago it was considered exceptional to have a few Sweet Pea blooms exhibited at the Temple Show, but in mid-April I saw some magnificent blossoms. Messrs. Dobbie and Co. have Sweet Peas the equal of which I have never seen at this period of the year, and we may expect a fine exhibit from them at the forthcoming London Show. Certainly the lovers of Sweet Peas owe a debt of gratitude to a grower like Mr. Andrew Ireland, with whom "streak" is unknown, and who proves conclusively that the Sweet Pea can be grown successfully both in the open and under glass, and that it does not require exceptional treatment, a fallacy still too rampantly prevalent. When will some readers realise the fact that successful blossoms can only be obtained if the root action is freely active and healthy? The gardener can know no set time for any particular operation, and more especially so the Sweet Pea grower. The soil must be in a fit condition, or the plants will not thrive. Therefore the man who, because it was March, and in spite of the rain, worked his soil, now finds that it is a mass of huge solid lumps, totally unusable. The precious Peas are shrivelling away, and success this year is impossible. Many are the grumbles one has heard during the past weeks, and all due to the fact enumerated above.

Abuse of Manures.—The market is flooded with "prepared plant foods," and an indiscriminate use of these will produce untold trouble and loss. At once let it be stated that Sweet Peas do not require gorging with stimulants. If a slight dressing of superphosphate, bone-meal and soot has been forked into the top soil previous to planting out, then nothing more is required until the first crop of flowers has been gathered. If a spell of very dry weather should set in in June, then watering with very weak soot-water is beneficial. By the way, a word of warning here may not be without profit. Soot-water such as I have often seen used—a thick, slimy, black slush, which leaves a coating upon the surface of the soil—is a positive danger. Soot should be put into a bag and the whole immersed in water, which extracts all the nutritive values, but the water remains only slightly coloured. This is the condition in which it should be used.

A Suggestion.—The notes on Sweet Peas that appear in *THE GARDEN* might occasionally be made more interesting if readers would forward any notes on difficulties or observations to the Editor. Many varieties of Sweet Peas differ in vigour of growth and colour of flower in different localities—some soils are specially suited for some varieties, while there are many varieties that require special treatment when given outdoor culture. These or any other points could be considered and fully discussed, and would be a welcome variety from a general article. Finally, every Sweet Pea lover should join the National Sweet Pea Society. In spite of what has been said about it, this society is flourishing and doing a great deal of good work. The secretary is Mr. H. T. Tigwell, Greenford, Middlesex, and the annual subscription is only 5s. M. CROW.

SOME BEAUTIFUL POPPY-WORTS.

THE MECONOPSES.

(Continued from page 230.)

AS already intimated, these Poppyworts love moisture, or that degree of uniform root coolness which is not a bad equivalent. In some measure, too, they prefer shade, though, with root moisture assured, this would only be desirable for securing greater longevity to the flowers, while in cold districts with much rainfall, shade should be altogether dispensed with. In these latter, too, shade would probably militate against the production of good pollen, and, in turn, seeds. Hence, in all the circumstances, a fairly open position, with root moisture, might be regarded as best. A fairly deep bed of soil well enriched by cow-manure should always be provided, loam, peat and leaf-soil constituting the chief, with cow-manure freely added. To those whose good fortune it is to be able to harvest good supplies of seeds each year, the importance of free grouping should not be overlooked, and it would be worth a long day's journey to be able to see a few hundreds of the nobler kinds in any garden. As yet, however, such a consummation is more in the nature of a dream-picture than anything else, though of subjects so unique such an ideal is worth striving after. Moreover, the plants themselves are so essentially worthy of specialisation, and if difficulties and disappointments bestrew the way, a greater honour and satisfaction will be the reward of he who first overcomes them. It may be, of course, that, like certain *Oncocylus* Irises, these Poppies, fretting for the conditions to which for ages they have been accustomed in their native wilds, refuse to be comforted in lowland places. But of this experience will be the best guide. The following are the best species:

***Meconopsis aculeata*.**—A beautiful species from the Western Himalayas, where it is found at altitudes varying from 11,000 feet to 15,000 feet. The leaves forming the rosette are pale green, deeply and irregularly lobed, and furnished with long, tawny-coloured hairs or bristles. In cultivation the plant is rarely more than 18 inches high at flowering-time. Flowers somewhat saucer-shaped and of a purplish sheen, which contrasts well with the yellow stamens.

M. cambrica (the Welsh Poppy) is well known and needs but little recommendation. A lover of cool, moist places, free in flowering, appearing in all sorts of places where perchance a seed or two may have fallen. It is one of the prettiest of all plants for naturalising. Though more or less perennial, it is best raised from seeds. The plant is dwarf, and produces a profusion of yellow flowers. The double orange and yellow forms are pretty variations, and there is room for more.

***M. chelidoniifolia*.**—A dwarf-growing perennial species from the Thibetan frontier. The flowers are clear yellow and an inch or so in diameter.

The leaves are deeply lobed and approximate in form to the Celandine (*Chelidonium*), hence the name. May also be increased by division.

M. grandis is also of perennial duration, happily, as it produces seed but rarely in this country. The plant comes from the Sikkim Himalayas, is of rather tall habit, and bears flowers of a purplish blue colour.

***M. heterophylla*.**—A free-growing, free-flowering annual species from California, which, producing seeds in fair abundance, is easily increased by these means. A somewhat variable kind of a foot or 18 inches high. The flowers, borne on slender stems, are red or coppery red, sometimes orange, and with a dark blotch on the petals. Quite an effective species when in flower.

A BEAUTIFUL BLUE POPPYWORT: *MECONOPSIS SINUATA* *LATIFOLIA*.

***M. integrifolia*.**—One of the most remarkable of the entire genus, and now well known to all cultivators of choice flowers. The most successful cultivator of it that I know is Mr. W. A. Milner, Totley Hall, who achieves considerable success with it year by year in his Derbyshire garden 700 feet above the sea. Mr. Milner raises the seedlings in the slight warmth already noted, and attaches importance to the method. The plant is found at 11,000 feet to 15,000 feet in the mountains of China and Thibet, where it grows in endless quantities. The great saucer-like flowers are of soft yellow colour, with orange-coloured anthers. The flowers vary in size, form, and in the number each plant produces.

The leaves are entire, variable in size, though always covered more or less with silky hairs. It is a moisture-loving species, of about two feet high when fully grown. No member of the genus is more worthy of specialisation.

M. nepalensis (Nepaul Poppy).—The plant formerly associated with this name had yellow flowers, the true plant having somewhat unattractive flowers of reddish purple colouring. Its fine rosettes of deeply lobed, hairy leaves approximate to those of *M. Wallichii*, and the plant is worth growing for its foliage effects alone.

***M. paniculata*.**—This is the yellow-flowered species formerly known as *M. nepalensis*, and is as good among yellow-flowered sorts as *M. Wallichii* is among the blues. The rosette of leaves has all the characteristics of the last named, save that the leaves are shorter. The plant is fully 5 feet high, a moderate seed-bearer, and one of the most reliable of the Himalayan kinds.

***M. sinuata latifolia*.**—This was at one time confused with *M. aculeata*, but differs from it in its larger, longer leaves and distinctly sinuate margins. In general habit it has much in common with the other species named, and attains the same height. The flowers are blue. It is a fairly reliable seed-bearer.

***M. racemosa*.**—The flowers, which are variable in colour, are neither attractive nor large, those I have seen being of a nondescript purplish or lilac tone and less than 2 inches across. The plant is about two feet high, has erect, unbranched stems, the flowers largely axillary. The leaves are entire.

***M. Wallichii*.**—To this fine Himalayan species must be given pride of place, whether viewed in the heyday of a glorious flowering or seen awaiting that time, when the great rosettes of leaves are a picture in themselves. If this queen of the Indian Poppies never produced a flower, it would still find those who would grow it for leaf beauty alone. Well-developed rosettes of leaves may be 2 feet in diameter, the soft, tawny-coloured hairs appearing above the grey-green of the groundwork. Seen after a shower with the raindrops still upon them the effect is very beautiful. In its highest perfection the plant may attain 6 feet to 8 feet, and with its noble pyramid of flowers is imposing indeed. The flowers vary from pale blue to purplish shades, the former the more desirable because of the glistening sheen-like effects with which they are

endowed; hence seeds should be saved from these alone. With artificial pollination seeds of good quality are fairly abundant and vegetate freely.

M. Delavayi* and *M. Rudis are recently introduced kinds not yet generally known, and there is also the quaint and brilliant-flowered *M. punicea*, one of Mr. Wilson's finds, which, if not now lost to cultivation, is at least extremely rare. Thus we have presented to us in a solitary genus species possessing quaintness, interest, or rare beauty sufficient, it would appear, to satisfy all tastes, while the innate fickleness or fastidiousness of some should provide for the problem-solver food for thought and material for experiment for many days.

E. H. JENKINS.

SEASONABLE NOTES ON CARNATIONS.

THE supporting of Carnations emerges as an important cultural item, which can never be delayed without serious after-results. There are several ingenious supports which obviate attention to tying; but even where these are adopted it is necessary to use the old-fashioned wooden or Bamboo stick to protect the plants while young, and for Malmaisons and Perpetuals other supports than these are of dubious utility. The value of a stick consists in its keeping the stem perfectly straight, a condition that was of little importance thirty years ago, but which is all-important at this date, when the blooms are valued according to the length of the stems. Young Perpetuals, moreover, when growing, as they ought to grow, with great vigour, produce shoots which will snap with the least touch, and these should on that account be staked when still young and slung to the stakes. Border varieties will very soon need attention, too, and unless the plants had short sticks applied to each when planted, which is sometimes imperative when they are extra strong, some will be sure to have grown off the upright. Invariably the young assistant places the stake on the wrong side of such plants, that is, on that away from the side to which the plant leans, whereas it ought to be inserted in a position to press the plant upright without having to drag it up with a tie. All Carnations should be staked in the same manner when off the upright. Bamboo tips are very generally used for supports, but I incline to use thicker stakes, which can each be split into four. These last longer, and are considerably cheaper than the tips.

Shading.—The great variety of shades in the colouring of the old pink Malmaison, or Princess of Wales as it is often called, is sometimes and to some extent due to the quality of the soil; but the colour can always be deepened artificially by applying a proper shading that will at once subdue the light in the daytime and keep the temperature cool. The best shading is undoubtedly one of the wooden or Bamboo blinds, and the worst is whitening. The whitening obscures the glass, and so far provides a shade, but it has a very slight effect on sun-heat. Perpetuals also are the finer for being shaded. Beacon burns very badly, and the strength and delicacy of all colours is affected injuriously by the sun's rays, and perhaps also from too high a temperature, which, however well ventilated a structure may be, becomes too hot for Carnations.

Outdoor Beds.—Plants to occupy positions in beds and borders out of doors may now be drawn from among those which are to remain to produce flowers under glass. Stand them meanwhile in a sheltered position where the sun does not reach them for the greater part of the

day, and be attentive to watering lest the young roots be dried up, the result of which will be a large number of yellow leaves later, an eyesore all the season. Of all the varieties I have tried, none is more floriferous than Mrs. F. Burnett, and those to reject are such as are of a weak habit, like Lady Alington, or not productive, like R. F. Felton. The plants may very shortly be planted out, setting them so that a shallow depression is left in which to pour water until the roots have got a grip of the soil, which at planting should be very firmly compressed. The quantity of flowers produced under attentive culture is quite astonishing, and more than repays the extra labour that they exact to establish them. These plants are, moreover, valuable producers of a superior type of cuttings for autumn propagation. Some growers lift the plants and derive cut flowers from them during the early

TWO BEAUTIFUL BROOMS.

IN the two Brooms illustrated, *Cytisus præcox* and *C. albus* (the white Spanish Broom), we possess two excellent spring-flowering shrubs. They are suitable for planting in varied positions in the flower garden, pleasure grounds and woodland. Whether in groups of several plants in the borders, masses on sloping banks, a bed or two on the lawn, or dotted about singly or several in a group in the open woodland, these Brooms are very effective. The soil for *Cytisuses* presents no difficulty; in fact, they flower more freely in soils which are light and sandy than in richly manured loams. *C. albus* is sometimes seen as much as 10 feet in height; more often 5 feet to 6 feet. In addition to the pure white variety, there is a form named *incarnatus*, with prettily tinted rosy red blossoms.

CYTISUS PRÆCOX AND C. ALBUS, TWO MAY-FLOWERING BROOMS.

part of the winter, and find them also valuable decorative plants.

Removing Shoots.—I do not think it is usual to disburden Carnation plants of extra growths, a point noted in an earlier contribution. It does not at this time of year matter so much in the case of Perpetuals, but those who grow a collection of borders or shows and Picotees in pots will find the plants ever so much stronger if the "grass" is reduced, where it is more, to six young shoots on each plant. If the more advanced of these are left, the majority will flower as well as the main stem; but it will be somewhat late before a second crop of shoots for layering can be had. It is all a question of what one wants. If lots of bloom, leave the largest; if very strong layers, remove these and let the later growths remain to gain strength.

Tynningham.

R. P. BROTHERSTON

The white Spanish Broom is readily raised from seeds. *C. præcox* is a natural hybrid, the supposed parents being *C. purgans* and *C. albus*. During the second half of April and extending into May the bushes are laden with cream-coloured blossoms. It has one little fault—the odour of the flowers is not at all pleasant. With age Brooms are inclined to become leggy, and for this reason they should be discarded and replaced with young plants.

Brooms are not easy shrubs to transplant successfully, except in a small state, and for this reason it is worth growing the plants in pots for a couple of years till large enough to place in their permanent positions. To obtain bushy plants, stop and shorten the young shoots freely in early life, as it is useless, when once the plants become leggy, to cut them down. As a third companion plant to the two named, grow *C. andreaeanus*, with rich yellow and reddish brown blossoms. A. O.

TWO BEAUTIFUL FLOWERING TREES.

AT this season our gardens and woodlands are rendered beautiful by a great many flowering shrubs and trees, but it would be difficult to imagine any that give greater pleasure to their owners than the two illustrated.

The Double-flowered Cherry (*Prunus Avium*).

The various kinds of double-flowered Cherries are easy to grow, and of a free-blooming nature, each year seeing the branches wreathed in blossom from end to end. There are a dozen or more double-flowered kinds, varieties of native and exotic species, and each has its special attractions. It is, however, doubtful whether any other kind is such a general favourite as the one under notice, a variety of the wild Cherry or Gean of our woods, and a relative of many of the cultivated varieties of fruiting Cherries of our gardens. Of vigorous growth, it attains dimensions equal to those of an ordinary Cherry tree, and average-sized trees may be between 35 feet and 40 feet high at maturity. From the time the trees are but a few feet high, or within a couple of years of grafting, they blossom freely, and continue to do so until old age deprives them of the necessary vitality. As in the case of fruiting Cherries, the pure white flowers appear from buds on the previous year's wood, and from short, spur-like growths on older parts of the trees. From three to four flowers, each $1\frac{1}{2}$ inches to $1\frac{3}{4}$ inches across, terminating a stalk 2 inches long, are borne in a cluster, three or four clusters often appearing together. An idea of the wealth of blossom produced by trees fifteen years to twenty years old may be gathered from the accompanying illustration. Like other members of the *Prunus* family, this variety thrives most satisfactorily in good, well-drained, loamy soil, and in preparing a position for a specimen it is worth while going to a little trouble to ensure these conditions. A station 10 feet across will not be too large to trench from $1\frac{1}{2}$ feet to 2 feet deep, and prepare with good soil, for the extra trouble and expense involved will be amply repaid by the additional vigour and beauty of the tree. It is perfectly hardy, and there are few parts of the country where it may not be planted, providing it can have shelter from violent winds while in blossom; for the purity of the flowers is endangered by exposure to cutting winds. One point which is worthy of consideration in the choice of a position for this tree is the selection of a site where a background of coniferous or other evergreen trees is available; for the white flowers are seen to far greater advantage by the aid of such a background than when exposed to the skyline. In addition to being such a useful outdoor

tree, young examples are valuable for forcing, and in February and March create a pretty effect in conservatory or greenhouse. An item in the cultivation of this tree which should not be overlooked is its dislike to severe pruning, for the careless removal of large branches is almost invariably followed by gumming, which may end in the death of the tree. When pruning is necessary, therefore, remove the branches carefully close to the trunk, pare the wounds round with a sharp knife, and provide a coating of coal-tar.

The Japanese Crab (*Pyrus floribunda*).—

Although often referred to as a species native of Japan, this showy tree is considered by many authorities to be of hybrid origin, the Japanese

as much in diameter, shapely specimens, well furnished with branches from base to summit, and about the end of April every branch is wreathed with blossom to such an extent that the woody parts of the trees are invisible. The flowers are a delicate pink, the colour being deeper and richer in the bud and when semi-expanded than in the fully open state. Growing with the type are several examples of the variety *atrosanguinea*, which is easily distinguished by its richer and deeper-coloured flowers. Where one specimen only is desired, it is advisable to select the variety in preference to the type; but where both can be grown, one helps to show off the other. Although mature specimens may be

met with as large bushes 12 feet to 15 feet high and 20 feet to 30 feet across, it sometimes grows into a small tree 20 feet to 25 feet or more high, with a very wide head, its size being determined largely by the conditions under which it is growing. For preference, it should be given a sunny position, sheltered from north and east; not that it is tender, but that cold winds from those quarters may injure the flowers. Provide deep, loamy soil, and see that the ground is well worked before the tree is planted. It gives little trouble; an occasional thinning may be necessary, but regular pruning is not desirable. American blight may attack it, and if such a thing happens, spray with a paraffin wash in summer and a caustic wash in winter. The fruits are not borne freely, and they have no pretensions to beauty. D.

A DOUBLE-FLOWERED CHERRY, *PRUNUS AVIUM*. THIS IS A VERY EFFECTIVE SPRING-FLOWERING TREE.

ROSE MRS. ARTHUR MUNT.

(HYBRID TEA.)

I HAVE frequently contended that this lovely Rose was badly treated when it was passed over by the judges who award the gold medals. No one who has seen it growing among the numerous pale-coloured varieties can resist its peerless beauty, and last year with me it was remarkably good. I can recommend it as a really good all-round variety. The colour is deep cream, which becomes

P. Toringo and the Asiatic *P. baccata* being suggested as its parents. In support of this theory there is the fact that it has not been found in a genuinely wild state, while the distinctly lobed leaves of the Japanese species may sometimes be noted among those of normal shape on branches of *P. floribunda*. Whatever its origin, it is an exceedingly ornamental tree, and was originally introduced to this country from Japanese gardens. No more worthy example of its value for decorative gardening can be found than the large group of a score or more well-grown examples which occupy a mound, interspersed with dark-leaved conifers, near the Water Lily House at Kew. Some of these trees are 15 feet or more high and twice

a sort of ivory cream with a peach tint as the blooms develop. The flowers are large, full and perfectly formed, with a high-pointed centre, and I can well understand Messrs. A. Dickson and Sons saying it is one of the very best of their productions. We are having such a large number of light-coloured novelties that it becomes quite embarrassing to know how to use them all, and yet there is such loveliness and distinctness in many of them that one cannot discard any. It will soon, however, become necessary for some authority to classify the various colours, especially the creams, buffs and pinks, and to let amateurs know which are really the best of each section.

DANECROFT.

ROSE-GROWING IN TOWN GARDENS.

Preparing for Exhibition.—Those who have tasted the joys of successfully exhibiting their Roses usually become enthusiasts for all time, and hence the number of competitors at shows increases from year to year, and Rose societies get more numerous. To ensure success at the leading exhibitions is the highest flight of the cultivator's art; but almost every town in the kingdom now boasts a horticultural society. Usually these have many classes to suit the smaller Rose-grower, and anyone who is sufficiently enthusiastic and painstaking may become a prize-winner. There is much benefit to be derived from exhibiting, apart from mere "pot-hunting." It instils enthusiasm as nothing else can; it enforces hard pruning—the most difficult lesson for the amateur to master—and it also stimulates the imagination and leads to the idealisation of the perfect bloom. Moreover, the ardent rosarian is in need of "letting off steam" from time to time. He must have others to see and admire his peerless blossoms, and to talk about them. Membership of a society gives him this opportunity, whereas if he meets no one of like tastes, and is compelled to talk "Roses" to the world at large, he is apt to become as great a nuisance as the too-intense golfer. A lack of confidence often causes the grower to postpone showing until a more favourable season, but this is neither good policy nor good sportsmanship. The putting up of a box of Roses, even if unsuccessful, teaches one much of the art of exhibiting that it is impossible to convey by chapter and verse, and it adds a fresh pleasure to life.

In Feeding the Roses an early start should be made, and cow-manure water is the safest thing to commence with. This should be given to the plants from the first week in May, using it very well diluted, and applying it about once a week. Towards the end of the month an artificial manure may be given alternately with it. Mix together superphosphate of lime and nitrate of potash in proportions of three to one, dissolving 1oz. of the mixture in each gallon of water. Let this be one week's diet, and the next may consist of a solution of sulphate of ammonia (half an ounce to the gallon of water). If these three stimulants are given in turn (of course, only to healthy and established plants), the Roses will have little excuse for failure. As the show-time approaches, a little sulphate of ammonia may be added to the contents of the manure tub, but it should be at a rate not exceeding 1oz. to four gallons when diluted. Do not bother about soot-water; it is messy and gives unnecessary trouble. Sulphate of ammonia contains exactly the same manurial properties, is infinitely cleaner and easier to handle, and the supply can be better regulated;

but care must always be taken to use it only in a very weak solution, the proportions never being greater than those given. The plants will have been pruned back hard, and this will increase the tendency of many kinds to throw several flowers from each stem. The shoots must, of course, be disbudded, but it is well to allow two buds to remain for a little time, until one can judge to some extent when the blooms will develop, and to guard against mishaps; but the grower must make up his mind as soon as possible which of these to discard. All plants should be carefully examined to see whether the growths have any tendency to touch one another, and if so, they must be staked and tied apart, so that the foliage may not be damaged by thorns. Every plant must be looked over daily for caterpillars, which frequently ruin the most promising buds before their presence is suspected. The shading, tying, arrangement and dressing

multiflora varieties which are really perpetual flowering from the time they open their first flowers in the middle of June right on into November, according to the state of the weather, of course. I have grown the varieties named below, and am much pleased with their behaviour. Quite the best way to grow this type of Rose would be as a hedge, allowing them to ramble away at will, occasionally removing weak growths to make room for the stout, sucker-like shoots that are being constantly pushed up from the main branches. The perfume in all of the varieties is most pleasing.

Trier produces large, pyramidal panicles of white flowers tinged with pink on opening, and with decided yellow anthers

Kommerzienrat W. Rautenstrauch (Lambert, 1910) is a strong-growing sort with very few thorns and good foliage. Its panicles of salmon red, with light yellow centre and a white shading on

THE JAPANESE CRAB APPLE, *PYRUS FLORIBUNDA*. THIS HAS CHARMING PINK FLOWERS THAT OPEN IN MAY.

of the blooms will be dealt with in the next article.

P. L. GODDARD.

PERPETUAL-FLOWERING CLIMBING ROSES.

ALTHOUGH we often hear of perpetual-flowering climbing Roses, I find them most difficult to locate. An odd bloom or two will at times open on certain plants through some check to growth, but such instances cannot class the varieties as perpetual flowering. I need hardly say I am not alluding to the many forms of Hybrid Tea Roses that really do go on flowering long into the autumn, like Lady Pirrie, for example; but I mean real climbing varieties like American Pillar or Excelsa, or even Félicité Perpétue.

By the introduction of Trier in 1904 Herr Lambert gave us the foundation of a perpetual race of

the outside of the petals, are produced over a long period. This variety is exquisitely perfumed.

Thermidor grows vigorously, throwing up strong flower-stems with huge panicles of extra large blooms, pale yellow, changing to white with age.

Hugo Maweroff produces its warm carmine, small double flowers of regular form in elegant trusses.

Fairy (W. Paul) is, unfortunately, of weak growth, therefore requiring much time to fill a given space, although this may be due to its great freedom in flowering. The single flowers are snow white, with yellow anthers.

Francois Juranville, although belonging to the wichuraiana section, is the most perpetual flowering of any variety in that section, but not so much so as the multiflora type. It is so useful for the continuance of its interestingly coloured flowers—bright salmon pink, base of petals orange yellow—that it deserves extended culture. E. M.

"THE GARDEN"

COMPETITION FOR PLANNING AND PLANTING THE LITTLE GARDEN.

FOR every great garden planned on spacious lines and expensively planted, there are a thousand little gardens which deserve no less thought and invention if they are to give their owners all the pleasure to be won from the happiest of recreations—gardening. Not so many years ago the little garden, whether in town or suburb, or even deep in the country, was a thoughtless affair; a few beds of Geraniums and Roses, a border of annuals and perennials in small and dull variety, and perhaps a shrubbery, all laid out without reference to the house or to each other. Since then, the cultivation of flowers and shrubs, fruit and vegetables has developed at a great speed. And it has done this side by side with a growing attention to the sister art of garden design, which includes not only the laying out of ground on simple and artistic lines, but also the use of flowers in harmonious groupings.

All this has been well understood and practised in the greater gardens, where an increasing reliance is set on those more formal qualities which made the beauty of the Old English garden. It remains to show that the little garden is no less capable of beautiful treatment. The miniature can be as great a work of art as the full-length portrait.

VALUABLE PRIZES FOR BEST DESIGNS.

The Proprietors of *THE GARDEN*, anxious as they are to stimulate the best interests of gardening in all its aspects, and to encourage correctness of design and planting in all sorts of gardens, have organised the competition of which particulars are now given.

Four Typical Sites have been chosen, and their plans are now reproduced on a small scale.

No. 1 shows a level site with a narrow frontage of 40 feet and a total depth of 120 feet. This is an average small suburban plot, and its lay-out and planting has an importance not ordinarily recognised.

No. 2 shows the type of garden which results when an enthusiastic gardener, living next door to a man who cares for none of these things, buys or rents part of his neighbour's garden. The L-shaped plot thus secured gives opportunity for variation in design which is impossible on a narrow rectangular plot. The site is level.

No. 3 shows a site such as is often found in the more distant suburbs of large towns, and even in the heart of the country, where there is a wide frontage and much less depth in proportion. This shape creates a new set of problems for the designer. The site slopes 3 feet downwards from east to west.

No. 4 shows a corner site formed by two converging roads, and its irregularity gives opportunity for unusual treatment. This site has a slope of 5 feet downwards from north to south.

RULES OF COMPETITION.

A Tennis Lawn is not to be attempted on Nos. 1 and 2; it may be, but need not be provided on No. 3; it must be included on No. 4.

Paving for paths, &c., should be shown where it is proposed to use it, but its cost should be remembered.

Frames or Greenhouse.—Place for two frames in No. 1 site, four in No. 2; and for unheated greenhouses in Nos. 3 and 4 may be, but need not be provided. If they are provided, due thought must be given to their being suitably screened from view from the house.

Architectural Features.—A sunk plat, a garden-house, a small pool, a pergola, treillage screens, seats, sundials, statues, &c., are permissible, but should be moderately used. Competitors should assume that the garden-owners have the following sums to spend, to cover cost of such things as frames or greenhouse and architectural features, also of hedges or trees which are to form salient features of the garden design, but exclusive of planting flowers, sowing lawn, &c.: For No. 1, £20; for No. 2, £40; for No. 3, £60; for No. 4, £100.

Treatment of Garden.—Competitors will use their discretion as to what proportions of the sites shall be utilised for flowers, fruit, vegetables, &c., but should bear in mind the average garden-lover rather than the specialist in one sort of cultivation.

Conditions of Entry.—The competition is open to anyone who cuts out the form of application on page IV. and posts it with four penny stamps to the Editor of *THE GARDEN*. (The envelope must be marked "Garden Competition.") This charge is to cover the actual cost of printing and posting two sheets giving the outline plans of the four sites. On these sheets the designs are to be drawn. Competitors may submit designs for all or only one of the four types. They will also be required to prepare (on a blank sheet, which will also be supplied) two planting plans, one for a bed or group of beds, and one for a border. It is left to the competitors' discretion whether they provide Roses, annuals or perennials. Bedding-out plants are discouraged but not barred. These plans are to be prepared in the way that Miss Jekyll has popularised. An example, which shows the method of drawing and size of lettering, is printed on one of the site sheets for the guidance of competitors. On the third blank sheet a bird's-eye view or perspective view of the garden may also be drawn if competitor desires. All notes and descriptions are to be printed on the drawings in bold and simple lettering, so that it can be read when reduced to a small scale. All drawing is to be done in black ink. The use of pencil or colour will disqualify, but perspectives may be wash drawings. The site sheets will be sent out to competitors rolled in a cardboard tube, *in which they are to be returned*. Drawings cannot be considered if they are returned folded. In order that anonymity

may be preserved, all competitors will receive with the site sheets a form on which they will give their name and address, and an envelope in which the form is to be enclosed. The drawings and sealed envelopes will be numbered at *THE GARDEN* Office on receipt, and the envelopes will not be opened until after the awards have been made. Where one competitor is especially interested in planning and another in planting, they may combine to send in a joint scheme.

Enquiries as to the Conditions.—Any competitor who does not fully understand the conditions of the competition should write an enquiry to the Editor of *THE GARDEN* on or before June 6. All such enquiries will be answered in the issue of *THE GARDEN* of June 20, 1914.

Date of Sending In.—All drawings are to be addressed to the Editor of *THE GARDEN*, 20, Tavistock Street, Covent Garden, London, W.C., marked "Garden Competition," and to be delivered on or before September 1, 1914.

Ownership and Return of Drawings.—The Proprietors of *THE GARDEN* reserve the right to publish any drawings submitted in any form they may wish. The winning designs and any others of special interest will be reproduced with the names and addresses of their authors in a special issue of *THE GARDEN*, which will be published as soon as possible after the judges have made their awards. All designs that secure prizes will become the sole property of the Proprietors of *THE GARDEN*, and copyright of the same will be strictly reserved. All drawings that do not receive prizes will be returned if sufficient stamps are enclosed in the envelope containing competitor's name. Great care will be taken of all drawings submitted, but the Proprietors of *THE GARDEN* will not be responsible for the loss of or damage to any drawing, howsoever arising.

Prizes Offered by "The Garden."—A first prize of 5 guineas, a second prize of 2 guineas and a third prize of 1 guinea will be given to the three best designs sent in for each of the four types, *i.e.*, there will be twelve money prizes in all, totalling £33 12s. In addition, there will be twenty consolation prizes, each consisting of books to the value of 10s. 6d., to be chosen by prize-winners from the *Country Life* Library of Gardening.

Judges.—The following gentlemen have kindly consented to examine the designs sent in and to make the awards: Mr. George Dillistone, Mr. F. W. Harvey (Editor of *THE GARDEN*), Mr. P. Morley Horder, F.R.I.B.A., Mr. Lawrence Weaver, Hon. A.R.I.B.A. (Architectural Editor of *Country Life*), and Mr. S. T. Wright (Superintendent of the Royal Horticultural Society's Gardens at Wisley). *The awards of the judges will be final and binding, and will not be subject to any appeal.* The Editor of *THE GARDEN* will not publish any correspondence relating to the awards unless it appears, in his sole discretion, to be of public interest.

DAFFODIL NOTES.

THE MIDLAND DAFFODIL SOCIETY'S SHOW, 1914.

A SHOW has been held at Birmingham without Robert Sydenham. This is the supreme fact to chronicle with regard to the 1914 exhibition. It is this which differentiates it from all others, for necessarily to a very large extent the flowers were the same, and necessarily, too, the general staging arrangements featured those of previous years; but no large-crowned, soft, fawn-coloured hat bobbing in and out among the crowd—here, there, everywhere! This was not there, and all that that hat stood upon. From the first Daffodil show organised by the late Professor Hillhouse in 1893 down to that of 1913 that hat had never been absent. No wonder, then, that we had come to look upon it as a something without which a show could not be. We were right and we were wrong. We have had a show, as we will have to have all our others, without it, and yet neither this nor those future ones which we hope for would, humanly speaking, have been possible without the life which he gave to the society and the painstaking toil and watchfulness with which he nourished its tender years. Lest we forget, "Robert Sydenham, Founder," is now an integral part of our official title. It is our formal tribute to his memory.

A remarkable event happened on the morning of the second day—our "silent salesman" spoke. Standing by me in front of the two classes of three distinct varieties of seedling Daffodils that have been raised by the exhibitor—Class 30 for old hands and Class 31 for novices—he pointed to the seventeen little lots that were staged in competition and said, "This is what I like to see." As these words fell from his lips I thought within myself, "And no one has done more than you to bring it about."

No parcel post firm of traders ever issued a catalogue of more alluring fascination than the splendid exhibits of Mr. Ernest Crosfield. The large, striking and refined blooms of which they are always composed are a tremendous stimulus to those who are just beginning to taste the sweets of home-made flowers. What an inspiration to stand before his tricolour-eyed Poet Ring Dove and observe the wonderful texture and substance of its beautiful round perianth, and note the green and yellow and red of its well-proportioned eye! How the large, cool-looking Barrii Anchorite fascinates us with its long segmented marble white perianth and its flat, large, lemon eye! What wonders of cultivation did we not see revealed in that peerless "nonsuch" Aladdin in the single bloom class for white-perianthed incomparables. It is $4\frac{1}{2}$ inches

from tip to tip. It has a little trumpet $1\frac{3}{8}$ inches long and $1\frac{1}{2}$ inches wide at the top, of a pleasing shade of yellow. Its petals are as smooth as a well-ironed shirt. The wider ones are $1\frac{3}{4}$ inches across and $1\frac{7}{8}$ inches long. I am told that this type is one which is hard to breed, but all this is forgotten as we go away, inwardly resolving to try if we can some day to be as fortunate as Engleheart was when he gave the world this magnificent beauty.

I know one young seedling-raiser who must have felt very pleased with himself at Birmingham (and his wife, too, for she was by his side, as she always is, helping with the Daffodils). I refer to Dr. Lower of Presteign. Had not his 234

THE POET NARCISSUS RING DOVE, RAISED BY MR. E. CROSFIELD.

the largest and deepest red cup in all the exhibition? The ivory-coloured perianth was slightly reflexed, and measured $3\frac{1}{4}$ inches in diameter. Placed on this and taking a round inch of its space was the deep orange red corona bordered with a narrow ribbon of the deepest Poeticus red. "A topping flower," said one, "to give colour to a big thing like Bernardino"; but, alas! the anthers are at present sterile and contain no pollen. I am given to understand that this may not always be the case, and that the keen doctor may live in hope. A beautiful double named Mary Copeland gives us the present high-water mark in this class. Not even Llinos, which I described last week as being the feature of the

London Show, has such a good back or such well-formed and symmetrical guard petals as this. There are two rows of them, broad and well proportioned, of a very pale primrose shade, next door to white. The interior is filled with the split-up corona, each little bit being of a deep yellow, broadly edged with orange red. It is a flower of no mean size, measuring, if my memory serves me, 4 inches across. It is a curious coincidence that two doubles of quite a new build, and each one very similar to the other, should have suddenly appeared in two consecutive weeks at the two great shows of the year.

Although I greatly admire the beautiful white Ajax from Holland, Mrs. E. H. Krelage, with its

white, well-formed perianth and its all but pure white trumpet—size: $4\frac{1}{4}$ inches \times ($1\frac{3}{8}$ inches \times $1\frac{3}{4}$ inches) \times ($1\frac{3}{8}$ inches \times $1\frac{3}{8}$ inches); although I liked the shape and colour of Mr. Welchman's rich golden yellow trumpet The Commonwealth—4 inches \times ($1\frac{1}{4}$ inches \times $1\frac{1}{2}$ inches) \times ($1\frac{1}{4}$ inches \times $1\frac{1}{2}$ inches) very much indeed; although I was charmed with the refinement of the pale Barrii Whisper ($3\frac{1}{4}$ inches \times $1\frac{1}{8}$ inches), with its pale citron cup and greenish eye; although the green in the Poet Raeburn's eye was so pronounced as to give the flower its great distinguishing characteristic; although I could say much of Sentry (a red-eyed Frank Miles), of Wilson's flat-eyed 672, of Charles Surface, of the clear-cut bicolor Ajax Mystery, of Madrigal (the pure-bred Poet that looks like a Barrii), of Allan-a-Dale (the wire-eyed Poet from Rye), of the recurvus-like Sonata, of the many beauties on the gold medal stand of Messrs. Barr and Sons, I must pass them by with this cursory notice in order to write more fully of what was to me the cynosure of the whole show, if for the moment I exclude from my purview the exceptional exhibit of Mr. Engleheart. I think it is Milton who writes of the "cynosure of neighbouring eyes." That was what Melanie was at Birmingham. A lady quite unknown by name or sight to me stood before it as I was making some notes, and touched my arm as if she had to have some outlet for her feelings, and said, "It is worth living to produce

a flower like that." The whole flower is a dead white, only relieved by the green eye of the cup. The three outer petals are broad and flat, while the three inner ones had slightly recurved edges. The bloom as a whole may be described as circular and not very large, being only $2\frac{1}{2}$ inches in diameter. It is a great achievement to have produced such a bloom, and I heartily congratulate Mr. A. M. Wilson on being the fortunate man to do it. Melanie, White Knight and a small yellow "peerless" raised by Mr. J. C. Williams I put in a class by themselves as super-refined, or possibly a better name would be superfine.

One charm of Birmingham is the quiet of the second morning of the show, when the keen ones

have the whole conservatory practically to themselves, and when one can take notes in space and peace and really look at things. I spent a considerable portion of the time at my disposal studying Mr. Engleheart's exhibit. I was attracted by the many pure white varieties which he had staged. They were collectively probably the best, largest and most varied collection that has ever been shown at one time. My good friend, the raiser, was kind enough to come and talk to me about them. I think he agreed with me in putting a long-petalled flower marked W—52 down as the greatest novelty. It measured $3\frac{1}{2}$ inches in diameter, and had a shallow cup seven-eighths of an inch across, which was pure white, while the perianth was a very pronounced shade of pale sea green, which appeared somewhat deeper in tone on the second day than on the first. When the two blooms were held against the pure white ones, the difference was very marked. W—128 (size: 4 inches \times $1\frac{1}{2}$ inches) is a large bloom, reminding one, in its cup more especially, of White Lady. The white segments are long and rather narrow, making between them a typical double-triangled perianth. W—153 (size: $2\frac{1}{2}$ inches \times seven-eighths of an inch) was an exact opposite. It was pure white, too, but there the resemblance ended. The petals were small, rounded, and with that delightful concavity which we describe as shell-shaped, and which I can recall in old days as giving much of its charm to the pretty Vanessa. The eye of the cup is a distinct grey-green, quite away from such a shade as we get in Emerald Eye. There were, too, on Mr. Engleheart's stand a whole series of a new type of Poet which suddenly appeared among his seedlings. To the casual onlooker they appear much the same as others, say, Raeburn; but as the faithful shepherd knows each sheep and can distinguish them all, so to the trained eye of the raiser these are very distinct, and constitute a new race. They are round in shape, have large, protruding anthers, thin, wiry stems, and have much green in the eye. He has a whole series of these, which he ranged side by side for my inspection. I think now I could pick them out; but what about it in a year? I shall see them no more till then, for the end of show-time has come. Good-bye, flowers! May you be there to be seen, and I to chronicle your charms in twelve months' time!

JOSEPH JACOB.

WATSONIA ALBA OR ARDERNEL.

This was introduced a few years ago by Mr. Arderne of Cape Town. In height it grows about four feet, bearing long, branching spikes of white flowers. When seen growing in a colony with a groundwork of low-growing plants, a beautiful effect is the result.

DAFFODILS NOT FLOWERING: CAUSE AND REMEDY.

[In Reply to Several Correspondents.]

SO many of our readers have this season been complaining of their flowerless Daffodils that we think it well to endeavour to clear the air in the matter—in other words, to give examples of cause and remedy. The bulbs in not a few instances are those of strong-growing garden varieties, which good cultivation and a favourable growing season should make all right. By "favour-

A HANDSOME TRUSS OF RHODODENDRON LODERI PINK DIAMOND.
(See page 248.)

able growing season" is intended that period of genial weather with frequent or abundant rains in March and April, when the Daffodil, developing its leaf growth, is also endeavouring to form a bulb which will be almost sure to give a perfectly satisfactory flowering in the year to come. For it should be known—is, indeed, known—to a very large number that the germ of the flowering we have recently enjoyed was really laid, *i.e.*, formed and existed in embryo, nearly a year ago. Hence much depends upon a genial springtime, the absence of cold, parching winds, for so moisture-loving a plant as the Daffodil.

But many will say: "We are at the mercy of the weather!" Exactly, and that is

where intelligent and generous cultivation to a large extent supplies the deficiency, should it exist. Another important item is early—August and September—planting, in order that root development may follow in season and in reason. Late planting is a prolific cause of failure, not of flowering, but of that good bulb growth which ensures success another year.

As already stated, the flowers that have been enjoyed during the past weeks were formed nearly a year ago, and where good cultivation obtained, not much has been wrong. The disappointments experienced during the same period have been in some measure due to the exceptionally dry spring of 1913; they have been far greater in the lighter soils and where good or generous treatment never entered into the scheme of cultivation.

Another prolific source of failure is caused by the amateur lifting and transplanting his bulbs in flower or leaf time; it is accelerated in those instances—and they are not infrequent—where the bulbs are lifted in clumps and transplanted in a similar way. One correspondent complains of the non-flowering of his Daffodils "this year and last year." They have been planted "four years, the leaves quite healthy." The only remedy in such a case is lifting, dividing and transplanting, with free room for development subsequently. Lift in July; replant a month or so later. Trench the ground deeply, just as the soil permits.

Manure liberally low down, *i.e.*, 6 inches below the bulbs. Do not forget a change of soil; nothing is so beneficial. Do not expect flowers immediately where there has been none for at least two years; at least a year's bulb development will be needed to achieve this.

THE GARLAND-FLOWER.

DAPHNE CNEORUM, otherwise known as the Garland-Flower, is one of the most charming of dwarf flowering shrubs, and an excellent plant for a shelf in the

rock garden. Growing only about six inches high, it spreads by means of sucker growths into a wide mass, which, throughout the year, retains its small, narrow leaves, and during late April and early May is a mass of pretty pink, fragrant blossoms. The flowers are borne in terminal heads $1\frac{1}{2}$ inches to 2 inches across, almost every shoot being crowned with flowers at the time named. Unfortunately, it is not everyone's plant, though in many places it grows like a weed. It appears to enjoy moist conditions at the roots, and thrives either in light loam or a peaty soil. Propagation is often carried out by dividing the clumps, each division with a little root forming in time, a distinct plant.

SEASONABLE NOTES ON VEGETABLES.

Cabbage.—The plants raised in boxes from seed sown in March will now be ready for planting out on heavily manured land in rows 18 inches apart, the plants 9 inches apart for the small-growing varieties which heart quickly, cutting out early every alternate head. When planted, cover the ground close up to the stem and for 3 inches wide with finely sifted coal-ashes, as a preventive of slugs eating the plants. Keep the ground well stirred among established plants, as this hastens growth; and if any batch seems slow of growth, sprinkle around each plant a pinch of nitrate of soda.

Carrots in Frames.—The latest-sown batch will need thinning and careful ventilation, tilting the lights on the opposite side to that from which the wind is blowing; water well, but carefully. Outside, sow small breadths of horn varieties for pulling in a young state. The earlier sowings will need thinning, stirring the soil between the rows.

Cauliflowers.—Make sowings of Mammoth, Autumn Giant and Magnum Bonum in frames, where the plants can be more safely raised than out of doors in dry weather. Directly the plants show through the soil, remove the lights and give an occasional dusting of soot and wood-ashes, which induces stocky and vigorous growth. If there is any danger of the plants being too thick, thin them carefully at an early stage, thereby obtaining sturdy seedlings. Plant out in drills those of previous sowings. In this way watering is more beneficial, as the roots derive the full benefit from the soaking.

Celery.—The February-sown plants that have been grown on in pots or beds in frames should be put out in trenches for an early supply. If an extra early crop is required, plant in frames or on a spent hotbed, giving abundance of water. Except for an early show, this crop is hardly wanted. The trenches for the first outside crop need not be made deep, as the variety will be of the dwarf section.

Peas.—Continue to sow Peas of the Marrowfat type at fortnightly intervals. Should the soil be dry, well soak the drills an hour before sowing, which will hasten germination of the seed. Directly the plants from any previous sowing appear above the ground, place black cotton over the rows as a preventive of birds. The rows, 4 inches high, should be earthed up, and have short stakes placed on each side prior to adding the taller supports. When the latter are put in, they should be placed upright. So many give them an inward slant on both sides, causing the tops to come so close together that the haulm there

receives no support, but is forced outwards on both sides, and in case of continued rains falls down through lack of support. If there is a promise of drought—as there is in May very often—mulch both sides of the rows with half-decayed stable manure as a preventive of the evaporation of moisture, which is a most certain forerunner of a mildew attack. The conserving of the moisture in the soil, too, assists freedom of growth. Early sown varieties for show, like Alderman, Duke of Albany or Quite Content, that are showing pods sufficiently for a crop, should have their points removed to conserve the energy of the plant into the swelling of the pods. Such plants should be freely supplied with

THE NEW REGELIO-CYCLUS IRIS LEUCOTHÆA. THIS HAS VIOLET BLUE SHADED BROWN FLOWERS.

water, and be lightly syringed in the afternoon of a hot day.

Tomatoes for Outdoors should now be planted against walls and fences. A southern aspect is the best site, although they succeed admirably on an east wall. The plants should be not less than 1 foot high when put out, and if they have been growing in 6-inch pots in a cold frame they will be all the better, as they will grow away at once and set fruit early, which much facilitates ripening in September. The soil should not be too rich, as the plants can be fed with liquid stimulants later on when the fruit is set and making the first swelling.

Swanmore.

E. MOLYNEUX.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Rhododendron Loderi Diamond.—A stainless, white-flowered hybrid of much excellence. The flowers are produced in loosely formed clusters.

Rhododendron Loderi Pink Diamond.—A counterpart of the above, with delicately shaded, pink-coloured flowers. These are obviously hybrids of the Aucklandii set, and have the same finely fashioned open, bell-shaped blossoms, which are about five inches across. No praise is too great for them. Exhibited by Sir Edmund Loder, Bt., Horsham.

AWARDS OF MERIT.

Rhododendron Gill's Goliath. A glorious rose pink flowered sort, with splendid heads of open, bell-shaped flowers. The richer colour is seen in the upper part of the flower; lower down the tube it is of lighter hue, veined pink on a whitish ground. Shown by Messrs. R. Gill and Son, Falmouth.

Iris Isolda (Regelio-Cyclus).—This delightful flower in bronze and gold approximates to the lovely, and until now unique, Charon. It is, however, of darker bronze, and possibly also larger-flowered. A gem of the first water.

Iris Leucothæa (Regelio-Cyclus).—A handsome form having violet blue standards, the bluish falls reticulated with grey and blotched with brownish crimson. It is very fine. These were shown by M. C. G. van Tubergen, Holland.

Syringa reflexa.—This distinct species is marked by unusually large leaves and racemes of lilac-coloured flowers, horizontally disposed. From the Hon. Vicary Gibbs, Elstree.

Auricula Majestic.—A very handsome self red, with yellow paste or centre. The pip is of large size; the truss finely proportioned. From Messrs. J. Veitch and Sons, also from Messrs. Phillips and Taylor, Bracknell.

NEW FRUIT.

Apple Sandling Duchess.—A very late cooking variety of excellent quality. Mr. S. T. Wright tested the fruits at Wisley, and reported that the cooking quality was equal to the favourite variety Wellington. The fruits are rich red and of moderate size. An award of merit was granted subject to an official inspection of the tree in the autumn. Shown by Mr. W. Crump, V.M.H. We heard many complaints about the fruits being removed before Fellows could see them.

The foregoing awards were made at the fortnightly meeting of the Royal Horticultural Society on May 5, when the flowers and fruit named were shown before the respective committees.

GARDENING FOR BEGINNERS.

RAISING SINGLE WALLFLOWERS FROM SEEDS.

AMONG spring-flowering plants, the Wallflower is one of the most useful and pleasing. In addition to the beautiful rich colours of the flowers, they are delightfully fragrant. No frame or greenhouse is necessary to raise Wallflowers from seeds. Sow them on a spare piece of ground during May and June or in shallow boxes, which may be stood in a light yet sheltered position outside. The best method is to sow Wallflower seeds in shallow drills 1 foot apart, as shown in the illustration. Having raked the surface soil to a fine tilth, draw out the soil from the drills to a depth of 1 inch to 1½ inches. Sow the seeds thinly, and fill in the drills. A sprinkling of lime and soot over the ground will assist in keeping away slugs and snails from the tiny seedlings.

Some time during July, according to whether the seeds were sown early or late, the seedlings will be ready to transplant. As a rule, the positions where the plants are to blossom are not vacant till autumn, so recourse must be had to another

piece of vacant ground. Tread this firmly, as it is very desirable to transplant Wallflowers in autumn with good balls of soil. Set out the young plants in rows 1 foot apart, and 9 inches from plant to plant in the rows.

There are two methods of increasing Daisies—by dividing up the clumps after flowering, as illustrated, and by seeds. Dividing or parting the clumps is done after flowering, usually in June. Each rosette of leaves or single growth, if carefully severed from the parent plant, usually has a few roots attached, and will quickly make a new plant. For a bed of young Daisy plants select, if possible, a piece of ground shaded from the midday sun. Set them out 6 inches apart and 9 inches between the rows. Here they may remain till the summer flowers are over in late autumn, when the plants can be transplanted with nice balls of soil to beds and borders. Instead of using Daisy plants as permanent edgings, numerous growers take up the plants after flowering and grow them in the reserve garden till the autumn, thus making room for Lobelia, Sweet Alyssum and other dwarf summer-flowering subjects. Three popular double Daisies are Snowball (white), Alice (pink) and Rob Roy (crimson).

Seeds of double Daisies may be sown during May and June on a border outside or in boxes in a cold frame. In due course, when large enough, prick out a patch or two of the seedlings 3 inches apart on vacant ground, where they will grow till the autumn. A good strain of seedling Daisies may be expected to come very largely true to colour. As a rule, the seeds are sold in colours, as double white, crimson or pink. Named sorts from seed are Longfellow (dark rosy pink), Snowball (white)

and Firefly (glowing scarlet, with yellow centre). The most notable development in seedling double Daisies in recent years is the Giant strain. These plants produce flowers 2 inches or more in diameter, by the side of which the ordinary strains appear almost as pygmies. Seeds of Giant White and Giant Pink may be purchased separately, or, if desired, a packet of Giant Mixed supplies a variety of shades from pure white to rosy red. It is worth while selecting a few of the very best seedlings and propagating them by division.

HOLLYHOCKS FROM SEEDS.

FORMERLY it was the practice to propagate Hollyhocks by division, grafting or cuttings, but the deadly fungus created so much havoc among the named sorts that the great majority of Hollyhocks grown in our gardens are now raised from seeds. These plants, having plenty of vigour, are less susceptible to the fungus. To secure strong plants for flowering next summer, seeds of single and double flowered Hollyhocks should be sown during May or June. Sow either in the open ground or in a cold frame. In due course prick off the seedlings in shallow boxes, as illustrated, and later

SEEDLING HOLLYHOCKS SHOULD BE PRICKED OFF INTO BOXES WHEN LARGE ENOUGH, AND TRANSFERRED LATER TO THE OPEN GARDEN.

plant them out in the open border. Seedling Hollyhocks may be raised in many pleasing shades of colour, including crimson, red, deep rose, pink, orange yellow, sulphur, and white. Hollyhocks vary from 6 feet to 10 feet in height, and flower from June to September.

ALPINE STRAWBERRIES.

BEING both hardy and adaptable, the alpine Strawberry can be grown in any garden, and will fruit freely the whole of the summer. Although birds play havoc with most other small fruits, they seldom interfere with this particular variety. Keep down weeds by hoeing whenever the necessity occurs, and mulch directly the blooms appear. If dry weather is encountered after the flowers begin to set, watering should be done until the conditions alter, otherwise the fruit will be small. A light dressing of nitrate or some other well-known fertiliser applied a month after starting to pick the fruit will do much to encourage continuous bearing. Keep the weeds well down all the year round and also keep the runners cut. The beds will stand for many years so long as the rooting weeds do not get established. Alpine Strawberries possess a quite different flavour to the ordinary Strawberries. They will, too, stand handling much better. Jam may be made from them. They are delicious with cream, and make an appetising stew. One great virtue is that they are certain croppers.

J. T. B.

DOUBLE DAISIES MAY BE PROPAGATED BY DIVISION, AS SHOWN, AFTER THEY HAVE FINISHED FLOWERING.

DRILLS MADE READY FOR SOWING WALLFLOWER SEED. NOW IS THE TIME TO DO THE WORK.

piece of vacant ground. Tread this firmly, as it is very desirable to transplant Wallflowers in autumn with good balls of soil. Set out the young plants in rows 1 foot apart, and 9 inches from plant to plant in the rows.

Wallflowers will grow in most garden soils. There are many positions for them in beds and groups, lines or whole borders; vacant spaces between shrubs may be filled with Wallflowers; while for window-boxes and terrace vases they are the best of all spring flowers. Wallflower plants, when in flower, are from 9 inches to 18 inches in height. Among numerous named sorts which come quite true from seeds, the following comprise a useful selection: Cloth of Gold, rich golden yellow; Blood Red; Vulcan, rich dark crimson, dwarf habit; Faerie Queen (Primrose Dame), citron yellow; Purple Queen (Violet Queen); Eastern Queen, salmon and rosy pink; Fire King, orange red; Ivory White and Yellow Phoenix.

PROPAGATING DOUBLE DAISIES.

As an edging for beds and borders in spring, double Daisies are among the gayest of low-growing plants at that season. With their tufted growths

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Melons.—As soon as the first batch of Melons are cut, the house should be thoroughly cleaned and preparation made for another plantation, and as the season advances a greater depth of soil ought to be provided in order to reduce the need of frequent watering. Melons may be planted from now to the beginning of August in numbers, according to the demand. Until the fruits are well advanced in each case the plants may be syringed twice daily, providing a temperature of 75° is maintained at night.

Cucumbers.—Frequent thinning and stopping will be necessary to keep the plants from becoming crowded. Give frequent waterings of liquid manure, and top-dress the bed as often as the roots appear through the surface of the soil. Rich loam and decayed manure will answer the purpose well.

Plants Under Glass.

Richardias or Arum Lilies which have finished flowering may be removed to the open air and moisture gradually reduced, in order to prepare the roots for potting about the end of July. Some growers plant them out; but where early flowers are desired, the best way is to grow the plants in pots, potting them up about the end of July or August and protecting them from heavy rain until the roots have made good progress.

Chrysanthemums.—Plants intended to produce large flowers should now be ready for their final potting. The compost may consist of good, rich loam, leaf-soil and decayed horse-manure. Pot firmly and leave some space for top-dressing later in the season. Fine sifted lime rubble should be mixed with the soil to keep it in a porous condition. Cuttings may now be inserted in small pots, in order to produce stocky plants for furnishing in November and December.

Verbena Miss Willmott.—This beautiful Verbena is suitable for the conservatory as well as for the flower garden. Plants rooted in March should now be ready for potting into 5-inch pots. A mixture of rich loam, leaf-soil and a little decayed cow-manure and silver sand will suit them well. Grow in a temperature of 55° and avoid cold draughts.

The Flower Garden.

Border Chrysanthemums.—Spring-struck cuttings should be planted out before they become pot-bound and stunted. Besides planting these on the mixed border, a plantation ought to be made on a break by themselves, especially if large quantities of cut flowers are desired during the autumn. Only early flowering varieties should be planted for this purpose, and they ought to be allowed a space of 2 feet from plant to plant.

Climbing Plants.—These soon become entangled if not regularly attended to and the shoots thinned and tied in the right direction. Many of the climbing varieties of Roses make far too much growth, and unless these are thinned out and trained, they will become a mass of rubbish. Clematises also require attention at least every ten days during the early part of the season.

The Rose Garden.—Careful attention must be paid to the destruction of aphids, which is almost sure to appear after cold east wind. Syringe the trees carefully with some approved insecticide, and see that they do not suffer from want of water at the roots. Roses which were planted recently should be carefully mulched with decayed manure, and if dry weather continues, a good watering ought to be given after mulching.

May-Flowering Tulips which are at present occupying the flower-beds may have to be lifted before they are quite ripe, and if such is the case, they should be carefully labelled and placed in the reserve garden until the bulbs are ripe, when they may be lifted and placed in the store-room until the time arrives for planting.

The Hardy Fruit Garden.

Watering.—In consequence of the unusual drought in April and early May, it will be advisable to examine the borders to ascertain if water is necessary. In the case of recently planted

trees, it is almost sure to be required, and this should be applied in sufficient quantity to thoroughly moisten the soil. If the borders were mulched, this will have done much to retain the moisture in the soil; but even then it may be necessary to give a thorough watering at once. Apricot trees which are necessarily planted in porous soil are generally the first to suffer, and if once allowed to become too dry at the roots, no amount of care afterwards will restore them to a healthy condition. All fruit trees in exposed positions should receive attention at once.

Gooseberry Trees.—Now is the time to guard against caterpillar. Let the trees be thoroughly syringed with some insecticide as soon as this pest makes its appearance. A dusting of soot and lime early in the season will do much to keep the trees free from this and other pests.

The Kitchen Garden.

Early Cauliflower.—Recently planted Cauliflower will require special attention. Weak liquid manure may be applied twice during the week, taking care to moisten the ball of soil thoroughly. Spring-sown plants for succession should be planted on well-prepared soil as soon as large enough to handle. These will require careful attention and protection from slugs, but will repay the cultivator if properly attended to.

Lettuce.—Spring-sown plants should now be ready for thinning and transplanting. Sprinkle the plants night and morning until they become re-established. Slugs may be kept in check by dusting the border with lime in the early morning. Make fortnightly sowings from now to the end of July, and, as the season advances, a cool situation should be chosen for them.

Brussels Sprouts.—Let these be planted out as soon as large enough, allowing 3 feet between the rows and 2 feet from plant to plant. The soil for this crop should be of a rather stiff nature and not too rich.

Radishes.—Make frequent small sowings of Radishes, choosing a position which is not too hot and allowing plenty of water.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Swede Turnips.—Every garden should have a number of rows (according to requirements) of this excellent winter vegetable. Unlike the ordinary garden Turnip, Swedes require a much richer soil and plenty of room to develop the roots. The present is a very suitable time to make a sowing, provided the soil is in condition for this, but, of course, they may be sown any time up to the beginning of June.

Globe Artichokes.—The protecting material may either be forked in or cleared away, and if the soil is at all dry, they will be greatly assisted by occasional waterings with weak liquid manure from the byre. Where extra large heads are in demand, the small ones that appear on the sides of the stalk should be removed, going over them several times.

Late Varieties of Peas.—As this sowing has usually to withstand the heat and excessive drought of the summer, it will be necessary to make provision accordingly. Dig out some small trenches as for Celery, and place some good farmyard manure in the bottom; then replace the soil. In sowing, place the seed a little deeper than usual, and by all means sow thinly. Indeed, I am not sure that growers would not get better results if the seed were dropped in singly.

Tomatoes.—There is usually a number of plants to spare after the house or frame has been furnished. These should always be planted on some vacant spot against a wall, preferably facing south. The fact that they have been standing about in pots will have tended to throw them into fruitfulness, and these very soon show flower. It is true the fruits may not be so fine as those grown under glass; all the same, the cook will find a use for them.

The Flower Garden.

Wall Climbers.—Too often these are allowed to take care of themselves. They become so intermingled that half their beauty is lost, whereas a little attention at this time in the way of training would amply compensate for the extra trouble. This is particularly necessary with many of the finer Clematises, which give such a glorious display in September.

Portulacas.—These lovely annuals, which are usually treated as half-hardy, may be sown now out of doors where they are intended to flower. They must have a position where they will be exposed to the full glare of the sun, and the soil should be of a light, sandy nature. Any vacant pockets in the rockery would suit them admirably.

Plants Under Glass.

Begonia Gloire de Lorraine.—Plants rooted last month will now be ready for a shift, and for this potting use a compost consisting of good fibrous loam, leaf-soil, sand, a sprinkling of brick rubble and a little dried cow-manure. It is important that they are not potted over-firmly, otherwise the young growths are sure to become stunted and run to flower. After potting, keep them in a warm, moist atmosphere, syringing them two or three times a day. Some of the older plants may be retained and grown on in wire baskets, when, with proper attention, they will make splendid specimens. Indeed, this Begonia is much more effective when grown in this way than in pots.

Gloxinias.—Young plants from seed sown in January will now be ready for potting on. Use soil of a free, open nature, and do not overpot. They will require abundant shade and an atmosphere charged with moisture. Older plants will now be greatly assisted by occasional applications of weak liquid manure from the byre. This will be found to suit them better than artificial manures. When the flowers appear, the plants should have less moisture, and if placed among the Maidenhair Ferns this will make a very tasteful arrangement.

Palms.—Those plants that have done service in the way of furnishing in the mansion will now call for attention. No matter how carefully they have been attended to, they are sure to be showing signs of their uncongenial surroundings. Trim off all decayed points and have every part thoroughly sponged, and before placing them in the Palm-house examine the drainage and top-dress with some turfy loam and a little Clay's Fertilizer. During the next two months they will require a heavy shade and an abundance of moisture. Under this treatment it is really surprising how quickly they recover.

Regal Pelargoniums.—These will now be coming into bloom, and where large specimens are desired, it will be necessary to stake them out. This, however, should not be overdone, as there is nothing more objectionable than any appearance to stiffness. They will require to be fumigated from time to time to ward off green fly.

Crotons.—Tops that were mossed should be potted up without delay. Have them placed in the propagating-case for a few days and shade from bright sunshine. Established plants should be fully exposed to the sun and frequently syringed during fine days. If some stock plants still remain, it will not be too late to root a few for decorative purposes in the autumn. If kept in 3-inch pots, they will be found to be extremely useful for dinner-table decoration. For this purpose they can be turned out of the pots and placed in small silver dishes. Treated in this way they are most effective.

Fruits Under Glass.

Thinning Grapes.—At this season the various varieties of Grapes will be coming on so fast that it will be a matter of concern to cope with the work of thinning. However one is pressed for time, this work should be carefully attended to. Go over the bunches that are thickly set and tie up the shoulders, and begin by cutting out all small and badly placed berries. The final thinning may be done when it can be seen how they are going to swell. The greatest care should be taken not to touch or rub any of the berries, as this would disfigure the bunch.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.
Hopetoun Gardens, South Queensferry, N.B.

SPRING FLOWER BEDS AT BOURNEMOUTH.

It would be very difficult indeed to find any other town in England where flower beds in the public gardens and open spaces are better or more artistically furnished at all seasons of the year than at Bournemouth. The summer effects in this seaside resort we have often seen and admired, but it was not until this year that we had been privileged to see the fine spring effects that the council's head-gardener, Mr. J. B. Stevenson, yearly places before the public.

It was in Queen Victoria's Jubilee year, 1887, that this worthy and highly esteemed gardener first came to Bournemouth in his present capacity, the neighbouring seaside resort, Swanage, having claimed his attention previous to that date. Since then he has seen some wonderful changes in the borough over which he keeps an ever-watchful eye, and it is only fair to add that most of the beautiful gardens and open spaces owe their charm, and in some instances their existence, to his energy, ability and enterprise.

Naturally, spring beds must of necessity contain a great many Tulips, and in using these Mr. Stevenson, by a simple yet ingenious plan, maintains a display of flowers over twice the ordinary period. His method is this: Wherever Tulips are to be used, two varieties of the same colour are selected, one an early sort and the other a May-flowering kind. The bulbs of these are planted fairly closely together and alternately, so that when the early varieties are finished, the later ones take up the running, and continue until it is time to empty the beds ready for the summer occupants.

In the little time that we had at our disposal we made notes of a few of the most effective beds, the date being April 29, and the particulars of these we record herewith for the benefit of our readers. It will be noticed that all the designs are simple, yet the effect of the beds, either in conjunction or alone, was excellent. (1) Munstead Wood Polyanthus, with a broad edging of Aubrietia Dr. Mules, thinly planted over with Tulip Wouwerman, pink, and Royal Crown; (2) Harbinger Wall-flower, with Narcissus Elvira thinly interspersed and boldly edged with double white Arabis; (3) two long beds planted with mixed Polyanthus, edged with double white Daisies

MR. J. B. STEVENSON, HEAD GARDENER TO THE BOURNEMOUTH CORPORATION.

and thinly planted with Tulips President Lincoln and Inglescombe Scarlet; (4) Tulips Prince of Austria and macrospella, planted rather thickly, carpeted with double white Daisies and edged with small-flowered red Daisy Firefly; (5) Tulips Eleanora (purple) and Blushing Bride, carpeted with double white Arabis and edged with Aubrietia Model; (6) Tulips Ophir d'Or and Bouton d'Or, carpeted with Aubrietia Hendersonii and boldly edged with Daisy Giant White; (7) Tulips Yellow Prince and gesneriana lutea, with Aubrietia Dr. Mules, and edged with Daisy Giant White;

(8) Tulips Mrs. Stanley and gesneriana lutea, carpeted with double white Arabis and edged with Aubrietia Model; (9) Pansy Empress, edged with Viola Snow Queen, and planted over with Tulips Pink Beauty and Blushing Bride; (10) Yellow Polyanthus, edged with Daisy Giant Pink, and planted over with Tulips Rosamunde and Picotee.

In addition to the foregoing there were a great many beautiful flower-beds. In the autumn, just before planting-time, we hope to induce Mr. Stevenson, whose portrait we have much pleasure in reproducing herewith, to give our readers the benefit of his long and varied experience in planning and planting spring beds. It may be of interest to record that he is the father of Mr. Thomas Stevenson, the well-known Sweet Pea cultivator and exhibitor.

THE NARCISSUS FLY IN NEW ZEALAND.

LARGE quantities of bulbs, mainly Daffodils, have arrived in Auckland by every English parcel post during the last four or five weeks, and before delivery they are subjected to an examination by an inspector appointed by our Agricultural Department. While the bulk of these parcels have probably been passed as clean and free from disease, several I know have been found to contain merodon (Narcissus fly) grub and been condemned. Unfortunately, this inspection is not infallible, for to my knowledge more than one parcel containing the dreaded grub has passed the inspection and reached the addressee, both this season and last. As the regulations of the Department at present stand, any parcel found to contain even one infested bulb is condemned and destroyed *in toto*. Thus,

while in their well-meant efforts to keep out this pest a large number of perfectly sound bulbs are unnecessarily destroyed, there is no certainty that the Narcissus fly is not already established here, for though in the cases to which I refer a close examination by the importer detected grubs previously overlooked, we do not know how many similar parcels passed into the hands of inexperienced persons who probably planted them without further scrutiny. I sincerely hope that we may have escaped,

SPRING FLOWER BEDS IN FRONT OF MR. STEVENSON'S HOUSE AT BOURNEMOUTH.

but I am not at all free from doubt, and I look forward to next season with some apprehension to prove whether my doubts are groundless.

Those growers here who have considered the matter have come to the conclusion that the examination of the bulbs before leaving home, which our Government insists on, is practically useless to detect merodon grub, for the reason that the parasite has not at the time of export developed; but during the six or seven weeks in transport it grows into a fat grub, and on arrival here its presence is not difficult to detect by carefully examining and squeezing the bulb.

The local inspector was interviewed, and he discussed the subject with us very courteously, and informed us he had had experience of the fly in the Old Country. We urged the futility of the preliminary examination in England, and that while it is highly desirable that all bulbs affected, or in the slightest way doubtful or suspicious, should be destroyed, we considered it wasteful to treat the sound bulbs in the same way. He expressed himself in sympathy with our views, but stated the regulations allowed him no discretion or latitude. He promised to represent the matter to his Department, and we hope the regulation may be modified; but until it is I would suggest to all English bulb merchants exporting to New Zealand that, if they wish to minimise the risk of loss to themselves and their Colonial customers, they should not pack Daffodils with other bulbs or in large quantities, but split up orders into small parcels, expensive bulbs being packed singly. This, of course, would entail extra trouble and expense, but at present I cannot offer any other suggestion. Unless some such course is adopted, I should not be surprised if a falling off of orders from this country is experienced; and it may not be inopportune to mention that whereas formerly there were two factors affecting the volume of business between England and New Zealand in Daffodils, viz.: (1) The trouble and time (two to three years) involved in importing and acclimatising; (2) the high price of most of the newer and better sorts; there are now two more likely to bear on the matter: (3) New Zealand raised seedling varieties equal (if not superior) to many of the English varieties which have so far been imported are now coming into commerce here at reasonable prices; (4) last, but by no means least, the Narcissus fly.

Auckland, New Zealand. A. E. GRINDROD.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

INJURY TO DAFFODIL FOLIAGE (C. D.).—The foliage of the Daffodils sent is insufficient to enable us to say with certainty from what disease they are suffering. You will probably find, if you lift them, that some pest is at work either upon the bulb or upon the root.

VERBENA MAHONETTE (Mrs. L.).—We do not recall a Verbena of this name, and wonder whether the variety of *V. tenera* known as Mahonetti is intended. All Verbenas may be grown in the open from May to September. Some, indeed, as *V. venosa*, are quite hardy in the London district, while *V. chamædryfolia* is nearly so in several places. Both these hail from Brazil, as also does the variety of *V. tenera* mentioned. Complete hardiness is, however, very much a question of experiment in differing localities.

IMPROVING THE SOIL OF A GARDEN (Blenheim).—As you gave your garden a good dressing of broken-up chalk last autumn, and presumably dug it in this spring, we do not think that you are in a position in this short time to say whether the plants will be benefited by the addition of lime to the soil. From what you say, we certainly think that the chalk should be of great service in such heavily manured ground. As the season advances you will be better able to see the effects of your top-dressing, and it will then probably give satisfaction.

PRIMULAS (M. J.).—Such Primulas as *P. pulverulenta*, *P. rosea*, *P. farinosa* and *P. Poissoni* do not require to be divided each year. The first two and the last named may be quite good for three or more years if provided with plenty of rich soil and root moisture for those first named. *P. farinosa*, while strictly perennial, gives by far the best results when raised periodically from seeds; indeed, the others only attain their greatest vigour when so treated. Seeds are so abundantly produced in many of the species, and vegetate so quickly if sown almost as soon as ripe, that division of the plants, because of the frequent unsatisfactory results accruing therefrom, does not receive serious thought. Moreover, the seedling plant, for robust vigour and generous flowering, is unequalled.

PEACOCK IRIS NOT FLOWERING (T. H. C.).—The most likely cause of the non-flowering is the smallness of the bulbs, and as they have all started well and appear healthy in other respects, it leaves but little doubt in the matter. In your sun-kissed California this delightful small plant should give but slight trouble, seeing that it requires little more than a sunny position, very sandy though comparatively rich and well-drained soil, and plenty of moisture at the roots during its season of growth. After the growing season it should be given absolute rest. Like many other South African plants, the above delights in sun and warmth, and probably even with you a raised frame in a sunny position would suit it best. Strictly speaking, it is not an Iris: the correct name is *Moræa glaucopsis*.

EASILY GROWN ROCK PLANTS (E. F. H.).—You cannot do better than concentrate attention upon the Aubrietias, Mossy Saxifrages and subulata Phloxes for the most part, which will also afford you a flowering for weeks on end. Of Aubrietias, take Dr. Mules (violet), Fire King (red), Lavender (mauve), Moerheimi (pink and white) and Lloyd Edwards (rich purple). Of Saxifrages, Guildford Seedling, Clibrani, Red Admiral (all high-coloured varieties), Lady Deane, Camposii and Arkwrightii (white) and Miss Willmott (white and blush). Of the Phloxes, Nelsonii (white), Model (pink), atropurpurea (dark red) and amœna (rosy red). *Achillea rupestris* (white), *Silene alpestris* (white), *Zauschneria californica* (scarlet), *Saxifraga aizoon rosea*, *Campanula muralis*, *C. pusilla*, Miss Willmott (blue shades), and *Thymus Serpyllum coccineum* (red) are also good and easily grown.

GENTIAN NOT FLOWERING (E. J. L.).—So far as we are able to judge from the fragments before us, the plants are anxious to flower, but are debarred from so doing by conditions of semi-starvation. The leaf growth, despite the evidences of a desire to run to flower, is quite inadequate; it should be twice or thrice as large. Hence we can but conclude that the plants are too poorly grown. In soils of a hot, sandy nature like yours, a comparatively liberal fare is necessary, and plenty of summer moisture.

In providing the latter you might also give a liquid manure twice weekly to encourage and develop the growth necessary to a good flowering. The fact that the plant continues growing is an excellent sign, and if you play your part and develop that growth to the utmost, you will have flowers and plenty of them in due course. The pathway is not an ideal position, though firm planting is necessary in all light soils, and with it a fairly generous system of cultivation.

TREES AND SHRUBS.

SHRUB TO NAME (D'H. S. S.).—The specimen sent for name is the Bird Cherry (*Prunus Pados*). It grows into a moderate-sized tree and blossoms freely.

INJURY TO RHODODENDRONS (Major M.).—We regret we are unable to say from the specimens sent what is attacking the Rhododendrons, though we suspect it to be a weevil. Perhaps you would keep watch and see exactly what it is and send us specimens.

CLIPPING A HOLLY HEDGE (H. K.).—A Holly hedge may be clipped at the present time, if you so wish, but it should be clipped again in autumn. Such hedges are usually clipped on the completion of growth, so that they may be left tidy for the winter. If, however, the hedge requires a severe cutting back, April is the best time for the work. It is very difficult to rid leaf-mould of insects, and perhaps the best plan is to spread it out in the sun and turn it a few times before it is used.

IRISH YEW (A Reader).—All that you can do to your Irish Yew, which does not appear to be recovering after being transplanted, is to cut the branches back by a foot or so and keep the plant well syringed two or three times a day while the weather is dry. It is usually advisable to remove a little of the branch growth of evergreens at the time of transplanting, in order that the effect of root injury may be lessened. Should the soil about the roots appear dry, give water now and then. A mulch of decayed leaves about the surface of the soil will also be advantageous.

ABOUT HARDY FUCHSIAS (Blenheim).—The height attained by the different Fuchsias varies greatly according to the locality, for in the more favoured parts of the country they form large bushes, while in others they are usually cut to the ground during the winter, and throw up new shoots each spring after the manner of a herbaceous plant. It is therefore evident that under these last-named conditions they will not attain anything like the height that they do where they grow untouched. The most vigorous of those mentioned is *F. Riccartonii*, which in such favoured localities as the Isle of Wight and similar spots will reach a height of 10 feet or 12 feet or even more. Less in stature come *F. longipedunculata*, *F. virgata* and *F. gracilis*, while *F. exoniensis*, the shortest of all, is, unless supported, about three feet high. The other two varieties we do not know. Where the plants die down during the winter and young shoots push up in the spring, the varieties named, with the exception of *F. exoniensis*, will reach a height of 2 feet to 4 feet, according to the vigour of the plants. All these Fuchsias, and, in fact, one may say the whole of the hardy kinds, flower throughout the summer and well on into the autumn, that is, should the weather be mild. All the pruning needed is in the spring, when the new shoots make their appearance, to cut out any dead wood, or occasionally it may be necessary to shorten a shoot in order to maintain the symmetrical character of the specimen.

ROSE GARDEN.

STANDARD ROSES FOR TOWN GARDENS (Blenheim).—The note on standard Roses for town gardens that you desire appeared in THE GARDEN for April 11. Reference to standards is as follows: "The two varieties better than all others for standard Roses are Hugh Dickson and Frau Karl Druschki, and having regard to the difficulty of obtaining good heads in the average town garden, most growers would do well to rely entirely upon these two sorts. Others which may be grown with fair, if not equal, hopes of success are Mme. Abel Chatenay, Caroline Testout, Mme. Ravary, Lady Ashtown, J. B. Clark, Joseph Hill, Mme. Melanie Souper and La Tosca."

ROSE FORTUNE'S YELLOW SHEDDING ITS FOLIAGE (Spa).—This Rose does not take kindly to pot culture. It may be owing to the sudden changes of the weather, but we rather think it is over-watering and the insufficient ripening of the growths. It would be much better if you could plant out the Rose under glass; it would have its growth better ripened. One of the secrets regarding the successful culture of this Rose lies in the pruning. As soon as it has ceased blooming, prune back hard all side growths, cutting them close to the main shoots. New growths will soon appear. The weakest shoots should be thinned out during the summer, and when growth has finished cut back hard all side shoots that have sprung from the other growths during the summer, and just remove the ends of the main growths. Afford good drainage and, when watering, give water copiously; then be careful only to water when required.

THE GREENHOUSE.

SCHIZANTHUS DYING OFF (Atherstone).—The Schizanthus is apparently attacked by a fungus nearly allied to that which produces a similar disease in Tomatoes. There is no cure, and it would be well to sterilise all the soil used in seed sowing and growing of these plants in future, as in all probability the spores are carried in the soil.

THE GARDEN.

NO. 2218.—VOL. LXXVIII.

MAY 23, 1914.

NOTES OF THE WEEK.

A Useful Wall Plant.—*Erinus alpinus*, in its varied forms, is a gem among plants that are adapted for planting on old walls, and one that is established without the least trouble if the seeds are sown in chinks or cracks, or even in moss if there is any on the wall. Such places look very bright at the present time, and will continue so for many weeks. All should grow it who have an old wall, for it will succeed there, while it often perishes on the flat ground if the soil is of a very heavy nature.

Lieutenant-Colonel Sir George Holford, K.C.V.O., C.I.E.—It affords us considerable pleasure to be able to reproduce a recent and excellent photograph of Lieutenant-Colonel Sir George Holford, Sir George is a deservedly popular member of the Council of the Royal Horticultural Society, and his valuable services are willingly and freely given on behalf of the Fellows. Visitors to the society's exhibitions will remember with very keen pleasure the magnificent groups of Orchids, Hippeastrums and other flowers that Sir George sends from his charming gardens at Westonbirt, Tetbury, Gloucestershire. At the great International Show held at Chelsea two years ago, his group of Orchids was easily the best that has ever been staged in this or any other country, not only on account of the rarity and wonderful variety of the plants, but also for the highly artistic manner in which they were arranged. It will be interesting to recall the fact that this magnificent group was awarded the cup offered by the King for the best exhibit in the show. Sir George was an Equerry to the late King Edward from 1892 to 1910, since when he has been Equerry to Queen Alexandra and an Extra Equerry to His Majesty the King.

A Beautiful Spring-flowering Tree.—In *Amelanchier canadensis*, the Snowy Mespilus, we have one of the finest of early blooming trees, and one that is not nearly so well known as it deserves to be. Its mantle of snowy white blossoms, which are disposed on short racemes and are so numerous that the tree becomes an almost complete sheet of white, produces a fine effect in spring and early summer. The usefulness of the species is enhanced by the fact that it flowers from the commencement, and plants 1 foot to 2 feet high bloom as freely as a tree 20 feet in height. It may be used in groups, or in a bed by itself, and in the autumn it is again made attractive by the richness of its deep red foliage.

Leaf-Blister on Peach Trees.—We have lately received many complaints about leaf-blister on Peach and Nectarine trees. This is caused mainly by cold wind, and especially after warm weather. The only remedy for this is to remove the leaves which are worst affected, and to encourage healthy growth as quickly as possible. The preventive is, of course, warm covering, which cannot always be applied. When warm weather sets in, the

the brilliant blue of the *Myosotis* is exceedingly fine, and Mr. Jeffrey, Captain Hope's gardener, is to be congratulated on the success of his scheme.

A Charming Little Rock Plant.—*Draba pyrenaica*, perhaps better known by the name of *Petrocallis pyrenaica*, should always have a place, even when the very choicest of alpine plants only are grown. Just now it is opening its delicate grey purple or heliotrope coloured flowers, which completely cover the whole plant, which is only an inch or so high. The colour may be termed a quiet one, but good patches are very effective. It requires a well-drained soil and a good open position. It is a charming little plant for the moraine, where it appears quite at home.

A New Hybrid Bomarea.—In the Botanic Garden, Cambridge, a beautiful hybrid *Bomarea* is flowering for the first time. It is the result of crossing *B. caldasiana* with *B. patocensis*, the former being the seed-bearing parent. It will undoubtedly prove to be a useful greenhouse climber, being quite intermediate between the two parents, having the free-flowering habit of *B. caldasiana* with some of the rich colour of the pollen parent, but of a much brighter red. It has been named *B. Banksii*, after the raiser, Mr. G. Banks of the Botanic Garden, Cambridge.

An Effective Combination of Wild Flowers.—While passing a wood the other day we were very much struck by the effect obtained from our common Bluebell mixed with the Greater Stitchwort or Satin Flower, *Stellaria Holostea*. The wood was a mass of blue, while on the edge of it were masses of the *Stellaria* growing among the Bluebells. The pure white of the Stitchwort formed a striking contrast to the deep blue. This is only one of the numerous instances how many of our native flowers could be used with good effect, particularly in some of the wilder parts of the garden.

Top-Dressing *Lilium speciosum*.

Plants which are growing freely and which were potted with the idea of top-dressing should now receive attention. No great quantity of soil ought to be placed round the bulbs at one time. It is better to top-dress again when the young roots are pushing through the surface. The soil may consist of turfy loam and leaf-soil, with a small quantity of decayed cow-manure and rough silver sand. As the shoots develop they should be carefully secured with neat stakes, and as aphides are sometimes troublesome, the plants may receive an occasional fumigation with nicotine compound to keep them in check.

LIEUTENANT-COLONEL SIR GEORGE LINDSAY
HOLFORD, K.C.V.O., C.I.E.

syringe, if applied twice daily, will soon restore such trees to good health.

Spring Bedding in a Scottish Garden.—A charming bit of spring bedding has been seen this year at St. Mary's Isle, Kirkcudbright, the seat of Captain Hope, R.N. This consists of a scheme of beds of the double *Arabis* dotted with plants of Sutton's Royal Blue *Myosotis*, with others of Wallflowers, both golden yellow and blood red. The effect of the snowy *Arabis* and

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Use of Grass Cuttings.—Forcing Rhubarb and Seakale out of doors with manure never seems to me a very clean way of managing. Even when the manure is only round the pots, some is apt to fall in when they are moved. It is a better plan to save grass clippings and make them into hay. Through the summer these can be mixed with the last fresh ones from the autumn cutting, and, piled round the Seakale pots, will make a splendid lining for the forcing-pit in the winter.—**ETHEL CASE, Bishops Waltham, Hants.**

Effects of the Recent Cold Weather.—Fortunately for ardent horticulturists, such a severe frost as was experienced on the evening of May 1 and in the early hours of May 2 is seldom known in May.

afforded by midday on the 2nd inst. ample food for thought.—**H. TURNER, Serlby Gardens, Bawtry, Yorks.**

Alpines on an Old Well-Head.—The photograph of the ancient well-head shows the cushion of *Saxifraga Boydii alba* to the left of the stone, as Mr. E. H. Jenkins, on page 214, issue May 2, wished to know what had become of the white sport of *S. Boydii* all this time. Our district is situated near the ancient Roman causeway Augusta-Vindobona, the Augsburg-Regensburg of the present day, and several redoubts and camps occur in this neighbourhood. There is little doubt that these well-heads, of which several were in the village, were fetched from a tufa quarry some thirty miles distant. They were each cut out of a solid block. They are about sixty inches across, and the thickness of the upper and lower rims is about nine inches, while the space between them recedes about one and a-half

The pride of the show, *Saxifraga longifolia*, which again reached 12 inches in diameter, flowered last year, and has not been replaced yet. I propose furnishing the spot with *S. longifolia* x *cochlearis*, which has similar flowers, but has the advantage of producing new rosettes after flowering.—**E. HEINRICH, Planegg, Bavaria.**

Lithospermum Gastonii.—Gaston's Gromwell is one of the most charming of all, but it possesses one great drawback in the minds of the would-be cultivator—it is remarkably troublesome in its ways. A good writer and cultivator says of it, with justice also, that it is "fairly hardy but rather difficult to cultivate. . . . One of the choicest of the whole family. They are lucky indeed with whom it will thrive." Some others have less difficulty, but the plant always remains comparatively scarce and is exceedingly troublesome to establish. It is well worth the trouble, so beautiful indeed is this 9-inch-high Gromwell, with its terminal clusters of azure blue, white-eyed flowers, borne for a while in the summer months. My object in writing this note is to point out that it may establish itself in what are unorthodox places, and that no one should despair of success without perseveringly attempting it under various conditions. Previous to an upheaval caused by removal I had established it in rockwork between stones in light sandy loam; but I was quite unprepared to see it not only growing but spreading freely in an ordinary border. This was in the garden of Mr. John Ferguson, The Hermitage, Duns—the raiser, by the way, of the delightful little *Saxifraga Fergusonii*.—**S. ARNOTT, Dumfries.**

Primulas Causing Rash.—Your correspondent "J. D.," in your issue of May 16, page 238, voices a warning concerning the rash-producing properties of *Primula obconica*, which are all too well known to many who have had it in their houses. I am sorry to see *P. malacoides* grouped with it, and, in common, no doubt, with many of those who admire that plant, would be glad to learn whether others have suffered from handling it, and whether the evidence for condemning it in "J. D.'s" case is quite clear of possible complication with *P. obconica*. It is a curious thing that many persons can handle the latter plant with impunity, while others cannot even handle its seeds without incurring the danger of rash, and momentary contact with the foliage, as in brushing past it, is, with them, sufficient to ensure irritation. In his admirable paper on Chinese Primulas read at the Primula Conference and printed in the Journal of the Royal Horticultural Society, Vol. XXXIX., Part 1, Professor Bayley Balfour says: "*Primula sinolisteri* is a plant of special horticultural interest. It was introduced in 1908 by Bees, Limited, grown from Forrest's seeds, and promises to be in our gardens what *P. obconica*, Hance, ought to have been, but is not. *P. sinolisteri*, Balf. fil., has not the irritant hairs. It is a free grower, forming compact masses of dark green, acutely lobed leaves, and the trusses of white (sometimes lilac) flowers are many. In our northern climate it is not quite hardy—like true *P. obconica*, Hance, in that respect. It was sent out as *P. Listeri*, King—a venial error of naming—and the name *sinolisteri* has been given in the hope of making the change of nomenclature less disturbing. *P. sinolisteri*, Balf. fil., is I am sure a plant of horticultural merit." It is evident that in *P. sinolisteri* your correspondent would have a plant that would exactly fit the purpose he requires it for.—**FRED J. CHITTENDEN.**

AN ANCIENT WELL-HEAD PLANTED WITH ALPINES IN A BAVARIAN GARDEN.

Here in this district (South Yorks) readings varied from 10° up to 14°, and the loss, as may easily be imagined, is most serious to fruit-growers. Notwithstanding very dry atmospheric conditions and the soil also dry, Plums and Damsons, even with the foliage well advanced, have been almost entirely ruined. Pears and Apples, too, I fear (although rather too early to say definitely) have had fully 75 per cent. of the crop killed, and this, I am sorry to add, after prospects were exceptionally bright. Currants and Strawberries, where unprotected, were likewise visited, but Gooseberries suffered little. In park and shrubbery, also, ample evidence may be found of how bitterly cold it has been. Some of the old Oaks look as though they had been badly scorched, and Sweet Chestnuts are equally sorry pictures, while even the common Laurel and Box trees had all new growth "nipped" badly. Japanese Maples and Wistarias appear to have been especially sought out, and what was on the afternoon of the 1st inst. a sight worth seeing of the latter.

inches. The place where the bucket was usually set down is noticeable in a deeply worn-out gap. When proper spring-water works were introduced, these well-heads become superfluous, and it was quite by chance that I was able to save one of them by paying 10s. for it, else it would, like its comrades, have been broken off for road-making. It had already been broken in two. I joined it together again, filled it in with a very stony compost, and planted it with alpines, which feel quite at home on it. To the left is seen the large tuft of the sport of *S. Boydii alba* of fifteen years ago; then follow *Androsace Chumbyi* (not in flower yet), *Saxifraga Elizabethæ* (the large dark plot), *S. valdensis*, *S. Aizoon rosea*, *S. cochlearis*, *S. albino Genderi*, *Dianthus microlepis*, *Leontopodium alpinum*, *Alsine Rosanii*, *Globularia nana* and *Erinacea pungens*. Down the back, not visible, is a patch of nearly a square foot of *Saxifraga apiculata* and another of *S. oppositifolia*, *S. lata* (Schott.), *Paronychia*, *Primula Auricula*, *Ramondia pyrenaica*, several *Sempervivums* and other things.

TWO BEAUTIFUL NERINES:

Pink: Dainty Maid.

Scarlet: Glory of Sarnia.

The Earliest Rose.—In reference to the question raised in May 9 issue by "C. T." as to the date of the earliest Rose bloom, I may state that I had a good flower of Bouquet d'Or open on April 20. The root of the plant is against an east-north-east wall, but the part of the plant on which the bloom made its appearance is trained against a wall with a south-south-east aspect.—E. A. C. McCURDY, *Oakdene, Ashted, Surrey.*

Primula ciliata purpurea.—Under this name I have a very fine hardy Primula, which belongs apparently to the varied and doubtfully descended class in which *P. Auricula* and *P. hirsuta* have a share. It is exceedingly handsome this year in a low, peaty bed which is moist all the winter, and which is treated to occasional soakings with pure water in the summer in dry weather. A good plant is very handsome with its large, prettily toothed leaves and its handsome trusses of purple, golden-eyed flowers. It evidently relishes the cool conditions under which it is grown, and casts in the shade a number of other plants growing in the same bed. The position is one which is largely shaded from the afternoon sun.—S. ARNOTT.

A Beautiful Tree in Scotland.—Nicholson speaks of *Dimorphanthus mandschuricus*, an interesting and ornamental plant, as a shrub, but I prefer to regard it as a tree. It is so seldom seen in Scotland that I think its hardiness must be considered doubtful, for anyone who knows it must agree that its striking inflorescence and subtropical-looking foliage entitle it to a foremost position among our ornamental trees, or shrubs if you please. Not only does it do well in the neighbourhood of Edinburgh, where I know of several good trees, but last season I came upon several healthy specimens at Dunecht, Aberdeenshire, the Scottish seat of Lord and Lady Cowdray. Dunecht is about thirteen miles from the coast, and it is no unusual experience there to have the thermometer down to zero. Of course, it is well to select a sheltered situation for this stranger from Manchuria, else its huge leaves are apt to be damaged by high winds.—CHARLES COMFORT, *Midlothian.*

Sweet Peas: The Question of Scent.—It is feared that recent improvements in regard to the size of Sweet Peas have been made, in part at least, at the expense of their perfume. Unfortunately, the trend of the modern grower is to endeavour to produce what can only rightly be described as abnormal blooms on ultra-long stems, regardless of one of the flower's undoubted fascinations, for the table—that of fragrance, with the result of the above-mentioned deterioration. The advent of the waved type brought about the first sign of this decadence, and now the delicious scent of a freshly cut bunch of the old (out of date) grandiflora sorts is to be cherished only as a sweet memory, unless, of course, one still grows for this original quality. The old cream variety, Hon. Mrs. Kenyon, was possessed of a delightful scent, which, in a somewhat lesser degree, is to be found in Clara Curtis and Queen Victoria Spencer. From that finest of all whites, Dorothy Eckford, very sweetly scented, we get a weaker quality fragrance in Moneymaker and Etta Dyke; while the old lavender favourite, Lady Grisel Hamilton, hands down some of its perfume through Frank Dolby, but less in that mammoth variety R. F. Felton, so dear to every exhibitor's heart. The lavenders or mauves are, however, all more or less still nicely scented. Speaking generally, my experience teaches me that the less the "wave" of a variety the more

fragrant will it be found. I will conclude these brief remarks with the mention of what, out of varieties which I have grown on my light soil (leaving out of consideration grandifloras, except Dorothy Eckford, which still remains the best white in colour, substance and scent) I consider to be the six most fragrant, in order of degree: Paradise Ivory, Dorothy Eckford, Clara Curtis, Queen Victoria Spencer, Frank Dolby and Moneymaker.—B. W. LEWIS.

Slug-Harboursing Alpines.—In my recently published book, "The Small Rock Garden," there is to be found a chapter—very brief, it is true—on the "Animal Pests of the Rock Garden," and, seeing that the ubiquitous slug is therein characterised as the "worst" of such pests, the subject of the present note may be considered as nearly related thereto. The first thing the rock gardener or lover of alpines must realise is that the slug is always present, and though he may appear to be taking his "days off" in a more or less erratic way, he may still be found asleep under cover of a neighbouring plant. Hence the title of this note. In other words, certain plants, such as Aubrietias, Veronicas, Phlox subulata varieties, *Acæna* and the like, all of which have prostrate, spreading tufts of leaves, may justly be regarded as of a slug-harboursing nature; and, of course, they are not alone. For the moment, however, it is the principle to which I would direct attention, the knowledge of where to look for this much-to-be-dreaded pest, which, while making nightly raids upon the choicest things a rock garden contains, does not remain in the immediate vicinity of such plants, but betakes himself to the friendly shelter of the slug-harboursing alpine, where he is content in the seclusion, shelter and uniform moisture such plants afford. To be quite sure of the reason for the slug betaking himself to such quarters, one has only to examine a slate, piece of board, or sack that has lain upon the ground for a few days, there to find one or more slugs invariably present. Hence, realising that the reason for his retreat is seclusion and cover, the gardener has only to imitate such conditions to get the slug into the trap. A portion of a rather thick Deal plank is excellent, better perhaps, for some reason unknown to me, than either the slate or sack; and though such things may appear a little unsightly in the rock garden, unsightliness is more easily endured than the ravages a few slugs may create. A surprising thing about the slug is the distance it will travel to get a bite from some choice morsel of alpine vegetation; hence one can only imagine that its sense of smell or appreciation following an earlier meal must be very keen. In the past we have been content to try a Cabbage leaf or two, but these are not of great service unless the whole of the under surface of the leaf is practically in touch with the soil. In the case of the wood trap, rough, partly worn planks have been found better than new, the slugs invariably clinging to the wood and not congregating on the soil. Damp wood, too, is better than dry; moisture, indeed, would appear an essential condition.—E. H. JENKINS.

FORTHCOMING EVENTS.

May 25.—Linnean Society's Anniversary Meeting at 3 p.m. Rhododendron Show at the Royal Horticultural Society's Hall, Westminster (five days).

May 28.—Bath and West and Southern Counties Society's Show at Swansea (five days). Royal Botanic Society's Meeting.

OUR COMPETITION FOR PLANNING & PLANTING THE LITTLE GARDEN.

As fully announced in our last issue, we are offering cash prizes of the total value of £33 12s., as well as a number of book prizes, for the best designs for planning and planting the little garden. Four typical sites, such as are usually met with for small gardens, have been chosen, and competitors may send in designs for one or all of the sites. The rules and conditions governing this competition are to be found in last week's issue, together with the "application form" which is to be used by the competitors. In case some readers did not secure that issue, they can enter the competition by filling in and posting to the Editor the form printed on page IV. This form must be accompanied by four penny stamps to cover the cost of the sheets on which outline plans of the sites are given and on which the designs for planning and planting are to be drawn. One of the objects of this competition is to emphasise the fact that the little garden can, and should, be planned and planted with as much care and taste as gardens of more pretentious dimensions. For this reason we hope that as many of our readers as possible will compete for at least one of the sites. The competition has already attracted considerable attention, and general satisfaction has been expressed that judges of architectural features as well as of actual planting have been chosen. So great has been the demand for last week's issue that it is practically out of print, but copies of the rules and the conditions of entry can be obtained on application, and will be sent post free on receipt of three halfpenny stamps. Ample time has been allowed for sending in the plans, in order that busy gardeners may have full opportunities of competing, and that our numerous foreign and Colonial readers may join in the competition.

THE CAPE BLADDER SENNA.

This beautiful flowering greenhouse shrub (*Sutherlandia frutescens*), is at its best as a rule in July and August. It forms an upright-growing plant, clothed with pretty pinnate foliage of a greyish hue. The drooping scarlet flowers, which are about one and a-half inches in length, are very suggestive of those of *Clanthus puniceus*. These are in their turn succeeded by inflated seed-pods, whence the popular name is derived. It was introduced from South Africa in 1683, and has long been grown as a greenhouse plant. Within the last few years it has, however, become very popular as dot plants for summer bedding, for specimens about three feet high will flower profusely. Last year it was very effective at Battersea Park, a large bed being planted with the variegated *Holcus mollis* and the crimson *Begonia semperflorens* Ruby, edged with a broad band of *Koniga maritima*. As dot plants over the bed were good examples of *Sutherlandia frutescens* in full flower, the general effect being a very pleasing one. It can be struck from cuttings of the young shoots, taken in spring, inserted into pots of sandy soil, and placed in a close propagating-case till rooted. Plants so propagated will flower in a smaller state than seedlings.

WATER-SIDE GARDENING.

COMPARED with former times, when the chief inhabitants of lake, stream-let or pond were little more than an unkempt mass of coarse grass or other herbage, the beautifying of the water-side to-day is almost reduced to fine art. In proof of this the reader has only to turn to the front page cover of the present issue. There will be seen at a glance all that is best in foliage and flower beauty—a superb fore-

we garden on a large or small scale, there will not be found wanting material of a suitable kind. Hence the larger areas may indulge the stately Reeds, as *Arundo Donax* in variety (where these are sufficiently hardy), the bolder Bamboos, giant Groundsels, *Polygonum* or Pampas Grass, while not forgetting the handsome *Gunnera*, which appears in splendid isolation above the Irises in the picture. Among hardy herbaceous perennials the *Gunnera* knows no peer, whether viewed from the standpoint of noble aspect or picturesque beauty. The plant, too, is at home by

room for full development as opposed to that species of massing which robs a plant of its right of action, it will not be lacking admirers. There are also *Primulas* of high merit for the cool, moist or sequestered spots of the garden, with *Rodger-sias*, *Saxifraga peltata* and *Trilliums*. Of the *Primulas*, such as *rosea*, *japonica*, *pulverulenta* and *Sieboldii* in variety all delight in moisture, whether at or near the water's edge or in woodland shade. Last, though by no means least, there is the great array of Japanese Irises (*I. laevigata*), of which a splendid grouping is portrayed on the front page. Rich in variety, producing shades of blue, white, red, crimson, and violet in single or semi-double flowers that may be anything from 6 inches to 10 inches across, they are gorgeous in the extreme, occupying a pedestal of their own for high ornament and flower beauty. No pen-picture could adequately portray the merits of this great and fitting final to a genus itself unique. They are usually in flower in July and August.

If in conclusion one might add a cultural note, it would be to say that soil and soil richness to these water-side plants cannot with impunity be ignored. By some the water—the moisture—has been regarded all in all, but it is only true in part. In conjunction there should be sweetness and the soil richness above referred to. Then, the "moisture-loving" subject should not be transformed into an aquatic. These Irises are a case in point. Revelling in rich food supplies, and coolness or moisture within reach of their root-fibres, they resent the permanently submerged condition, and unmistakably when planted in brick earth. In lighter loams or those rich in vegetable matter in which

the roots can ramify freely, they give of their best, and in their season are a source of pleasure and delight.

E. H. JENKINS.

BERBERIS STENOPHYLLA EFFECTIVELY PLANTED BY THE WATER-SIDE. IT HAS GOLDEN YELLOW FLOWERS AND IS QUITE HARDY.

ground mirrored into fullest life by a foil savouring of the ideal. Within the limits of such a setting as the picture portrays it would be possible to accomplish much—possible, indeed, by inserting some of the best of Nature's jewels to display both the gems and the setting at their fullest worth. Herein lies the "art which doth mend Nature," and the gardener who accomplishes so much has already elevated the gardening art to the highest rank. It may be said that a scene like that depicted would only be possible in like circumstances; that the picture minus the framework would lose half its charm. Exactly. At the same time I would point out that it is the wedding of the two which constitutes so beautiful a whole. One may look in vain for incongruities, only to find a picture of high ornament and realistic effect. As a whole it is ideal; invaluable as an object-lesson, even if not possible in all circumstances of reproduction in detail. To have such a picture in the mind's eye when engaging in water-side gardening would be worth much. To mould, modify or adapt to special requirements is the work of the moment, and with the ideal in view the gardener need not err. It is all a question of making the most of opportunities; and whether

the water-side, and though not requiring its roots submerged, revels in cool places and rich and deep soils. There are boldness and distinction, too, in the towering creamy plumes of giant *Astilbe* and Goat's-beard *Spiraea*, the last-named genus also affording colour shades of pink and carmine not found elsewhere. Then for flower beauty and grace combined none can compare with the tall-growing North American Panther Lily, whose crimson flower-shafts, 8 feet or more in height, show well amid willowy Bamboos and delight in their shelter-affording sheaves. These Lilies are most happy in peaty earth, though soil richness is much to their liking.

For smaller areas the gardener may indulge in the newer *Astilbes*, hybrid descendants of *A. sinensis*, *A. s. Davidii* and others, which are peculiarly adapted for the water-side. There is also the unique *Spiraea palmata* from Japan, than which no herbaceous kind is so endowed with flower wealth. Given deep, rich, cool soils or root moisture, the spreading rosy carmine cymes of blossoms appeal to all, the well-marked leafage being appropriate for so meritorious a plant. Two and a-half feet or 3 feet high, amply habited and self-supporting, it is a plant for all, and, given

BERBERIS STENOPHYLLA.

This beautiful Barberry is said to be a hybrid between *Berberis empetrifolia* and *B. Darwinii*. Its successful cultivation presents no difficulty, as it seems to grow well on most soils and situations, and it can be used successfully for almost any position in the pleasure ground. As an isolated lawn specimen it is particularly graceful, its long, slender shoots spraying over with a fountain-like effect, which is beautiful at all seasons, but especially so when the plant is covered with a profusion of bright golden yellow flowers, almost hiding the foliage from view. It is also eminently suited for planting rough and steeply sloping banks, where it gives a beautiful cascade-like effect. It is equally at home on the margins of woods and shrubberies, and also planted in good bold masses in thin woods. In common with many members of this family, it does not transplant well when it is large; but young plants present no difficulty in this respect.

It is surprising that it is not largely used as a hedge or screen, for which purpose it is very beautiful; but it should not be clipped with the shears, as this destroys the character of the plant. The trimming or pruning should be done with the knife, simply picking out and shortening back the too strong and rampant shoots. This operation is best done after it has finished flowering. Trimmed in this way, the hedge is kept sufficiently dense and the graceful habit of the plant preserved. In the Southern Counties its flowering season is usually from the end of April to the middle of May. The plant is easily propagated by means of layers laid down during the autumn, or by cuttings of the ripened wood put in sandy soil in a cold frame.

BORDER CARNATIONS FROM SEED.

THAT the border Carnation is an easy plant to grow to perfection few would maintain, but in spite of recent opinion to the contrary, I firmly believe that in most parts of these islands this plant can be very successfully grown

without the aid of glass. In the moister parts of Britain I believe it would be difficult, for though layers which are well established in autumn will withstand severe frost with impunity, they will quickly succumb if their roots come in contact with stagnant moisture, and damp atmospheric conditions are most favourable to the fungoid diseases, which are, perhaps, the worst foes with which the Carnation grower has to contend. These difficulties are greatly reduced in well-drained districts; but from planting in September to flowering in August is a long way, and when wireworm and eelworm, slug and sparrow, aphid, rust and spot have their toll, there is small wonder that the outdoor culture of Carnations is a difficult, though possible, task.

To be successful, a great deal of time, ingenuity and patience are desirable, even to make the best of a few hundred plants, and many have not the requisite time, without which skill and enthusiasm are of little avail. There are doubtless many who have tried Carnation-growing under these conditions, and their efforts have ended in disaster, and these are they who are easily led to believe that the border Carnation is a difficult plant, a specialist's fancy, and as such best left to him with as little envy as possible.

To these—who would grow Carnations, but have had trouble with named varieties—I should like to recommend the trial of seedlings. To those who have not done so, a new delight is in store. But here a word of warning: there are seedlings and seedlings. If ever there were a time when something could readily be obtained for nothing, such time has gone, and if Carnation seed is to be grown, it is waste of time to use anything but the best. Several specialists in Britain, whose reputa-

tion is world-wide, retail hand-fertilised Carnation seeds at half-a-crown for the hundred, and a better investment a gardener cannot make. There will be more genuine pleasure from such a packet than from a pound of the inferior stuff often sold as Carnation seed. This is the first point; the second is, sow early.

May is a good month to sow, and seedlings which are above ground by the end of the month will prove very satisfactory. The seed germinates quickly, and the seedlings are very liable to damp off unless care is exercised in watering. As soon as they can be handled, prick off into boxes or sheltered beds, and by the third week in July they will probably be about the size of small layers, and should then be planted in their permanent quarters. A plot well manured for the previous crop should be made very firm, and the plants put in 16 inches apart each way, a wider alley between every series of five rows proving very useful at a later stage. Planted very firmly in this manner, they will be well established before winter, and will make a useful root system, though top growth will not be great until spring, when the beautiful green-grey shoots

quite possibly no two plants in the batch being alike; but though each may not be a Daffodil Elizabeth Schiffner, there is sure to be something, at any rate, worth preserving, if only for one's own use, and there are always with these plants the pride of the raiser and the sense of something accomplished which more than recompenses for some slight fault of form or colour to which a mere florist or envious neighbour might point. If this be not too long already, I should like to add a census I took of the results of one packet of seeds bought from a leading grower in the South: Sowed, April 27, 1911; 100 seeds; plants, 93; singles, 3; selfs, 23; fancies, 23; white-ground Picotees, 3; yellow-ground Picotees, 11; flakes, 14; bizarres, 5; did not bloom, 7; died through various causes, 4. The number of singles alone speaks for the quality of the seeds.

East Yorks.

F. M. S.

WISLEY GARDENS IN MAY.

WHILE visitors are attending the Royal Horticultural Society's Show at Chelsea in almost alarming numbers, only comparatively few find

CYTISUS PURGANS GROWING AMONG HARDY FERNS AT WISLEY.

must be protected, where sparrows are abundant, by black thread tightly stretched across the beds. To the writer's eye, there is no more pleasing sight in a garden than a bed of healthy Carnations at this season. Timely and careful staking, and an assisting sprinkling of manure, will bring the time of blooming along, generally a month earlier than that of layered plants; and to examine the shapely calyces morning after morning is a mingled pleasure and exasperation—they are often so slow in opening that it is almost impossible to keep itching fingers from assisting in the revelation of self or flake, quaint bizarre or dainty Picotee

their way to the society's beautiful Surrey gardens at Wisley.

The Rock Garden.—This is one of the more recent additions at Wisley, and it is destined to be one of the great features of these beautiful gardens. Bright patches of colour crop up here and there among huge boulders of rock, and the whole scene appears like a mountain slope clothed with richly coloured alpine flowers. There are Saxifragas in endless variety. *S. decipiens* and *S. Wallacei* make bright patches of white, while *S. Red Admiral* and *S. bathoniensis* vie with one another in brilliant red hues. The alpine

Wallflowers in orange yellow tones make a pleasing contrast to the Iberis and Arabis, which look like drifts of snow in the distance. Aubrietias in varying shades of purple, Arenarias and Violas in variety also lend pleasing shades of colour in the rock garden. Primula involucrata, too, is looking very dainty under the shelter of a rocky ledge, while in bright sunshine Gentians are induced to open their flowers of steely blue far more freely than they usually do in an English garden. In damp and shady places the American Wood Lily is flowering freely, while the moraine is full of interesting gems, some of which promise to flower well a little later on.

Flowering Shrubs.—Now that the Prunuses are passing over, the Hawthorns, Lilacs and Laburnums keep up a succession of blossom among the trees and shrubs. Viburnums, too, are very fine, and the same may be said of the

COLOURED PLATE.

PLATE 1494.

TWO NEW NERINES.

WHEN in flower, Nerines are among the most beautiful of all greenhouse bulbous plants. Some of the flowers are of beautiful art shades in colour, and many of them when seen in sunlight show a diamond-dust effect on the petals which is truly exquisite. The varieties Dainty Maid and Glory of Sarnia were shown before the Royal Horticultural Society in October last by Messrs. Barr and Sons, Covent Garden, to whom we are indebted for the following particulars and for the flowers from which our coloured plate has been prepared. Both varieties were raised by Messrs. Charles Smith and Sons of Guernsey.

temperature of 45° to 50°. The mistake which is often made in growing them is that they are given too much warmth. It is very important that they should have an abundance of air and light. The bulbs ought to be potted up in the summer in a compost of rich sandy loam with a little charcoal, and when in growth should be watered freely, a little liquid manure being occasionally given them. During the winter a free foliage growth must be encouraged, and when this begins to turn yellow in the spring the watering should be suspended and the pots placed on a warm, sunny shelf."

RAISING NEW ROSES.

[In Answer to a Correspondent.]

We are glad you find *THE GARDEN* so interesting. It must be a great joy to yourself to read of what others are doing, even though deprived by sickness from entering into the work more fully yourself. If you have a small greenhouse, you could produce some seedling Roses, for it is very simple, and although you could not carry out the work upon scientific lines as do the great raisers, yet there would be a rich fund of pleasure accruing even from a small effort. The novelties are raised from seeds produced under glass. Established plants are made to bloom about March and April, and their flowers cross-fertilised. Suppose you desired to obtain a cross between, say, Willowmere—which we may illustrate during the summer—and Rayon d'Or, you would contrive to have these two Roses in bloom at the same time. Before the flower of Willowmere had developed, you would remove all the petals, then cut away the stamens before the pollen grains burst. These pollen grains are contained in the stamens, as you doubtless know. The flower would then have its pistils remaining. Upon these pistils the pollen would be transferred by a camel-hair brush from the developed flower of Rayon d'Or, and in course of time the fruit, seed-pod or hep would appear. This is allowed to hang upon the plant until ripe, that is, until it turns yellow or red, whichever the case may be, for these fruits of the Rose assume remarkable colours and shapes,

A BEAUTIFUL COLONY OF PRIMULA JAPONICA IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT WISLEY.

Brooms, of which Cytisus purgans is unquestionably one of the very best. This species has bright golden yellow flowers, and it is said to be one of the parents of C. præcox, the other supposed parent being C. albus. The Azalea garden is now a perfect mass of colour in warm tones of orange, yellows and fiery reds. There are no other flowers that can vie with Azaleas for colour effect.

In the Wild Garden.—The greatest charm of these gardens we leave until the last. It is the wild garden, preserved in much the same form as it was in the days of Mr. G. F. Wilson, the late owner. Here may be seen Primula japonica in tens of thousands under the shade of trees and clothing the banks of a small stream. Our illustration shows a winding pathway through the woodland with a wealth of flower on either side.

On another page will be found a reference to the Tulip trials at Wisley.

"The parentage of Dainty Maid is Nerine crispa (seed parent) × N. Fothergillii (pollen parent). It is a very elegant and delicately coloured variety, growing 16 inches high and having an umbel of flowers measuring 5 inches across. The floral segments are narrow and prettily undulated, and of a delicate flesh colour. The parentage of Glory of Sarnia is N. coruscans major (seed-bearing parent) × N. Fothergillii major (pollen parent). This is a most brilliantly coloured variety, producing umbels of medium-sized flowers, and with prettily recurved and undulating floral segments; colour, lustrous fiery orange scarlet, having the appearance of being bespangled with gold; height, 16½ inches. This plant received an award of merit from the Royal Horticultural Society.

"With regard to culture, these Nerines are easily grown in a cool greenhouse having a winter

some appearing like miniature ripe Jargonelle Pears, others round like miniature Tomatoes. When the fruits or heps are ripe, they are placed in damp sand, and at Christmas the seeds are taken out and sown in pots or boxes. Sometimes one pod or hep contains as many as thirty seeds, and if all of these germinated they would most probably all be different, some worthless, others perhaps superior to either parent, for, you see, there is always an element of chance. One may produce a really startling novelty from just a pod or two, or one may sow thousands of seeds and not obtain a novelty of merit. But we view the matter from the same point as the late Lord Penzance, who raised the Penzance Briars. He said that if the novelties were not of very great merit, they at least gave their raisers varieties no one else possessed, and to have such growing in one's garden must add greatly to its charm.

REVIEW OF THE SPRING SHOW AT CHELSEA.

EQUALLY as good in quality and far better arranged than the International Show of 1912 aptly describes the great spring exhibition of the Royal Horticultural Society which opened at the Chelsea Hospital Grounds on Tuesday last. This year the Large Tent, covering an area of over two acres, is devoted to groups arranged on the floor, so that visitors have ample room to walk between them and admire the flowers. This is an improvement on the last show, when the tables in this tent were too close together and the gangways too narrow, with the result that visitors had considerable difficulty in moving about. The ventilation of all the tents, too, has been considerably improved, and it is evident that the Council are making efforts to study the convenience of visitors.

Outdoors, rock and formal gardens abound. In many instances these leave little to be desired, good taste, both in planning and planting, being evident. In a few instances, however, there seems to have been a peculiar lack of restraint in the use of stone. One would have thought that the enormous expense of conveying many tons of stone to an exhibition would have had the effect of keeping this in its proper proportions. We hope the day will never arrive when this great show will more closely resemble a stone-mason's yard than a series of natural gardens. In surveying these rock and formal gardens we were rather at a loss to understand the curious mixtures of natural gardens and artificial displays that the Council have tolerated. We cannot conceive anything less gratifying to the mind or eye than well-designed rock gardens cheek by jowl with glaring white and gold pillars and teak-wood seats. This indiscriminate letting of sites for sundries is not to the ultimate advantage of the society, though the pecuniary reward at the moment may be a consideration. The tea tent, also, necessary as it was, could surely have been more appro-

priately situated than between two sets of rock gardens. Red and white striped canvas does not harmonise with grey lime-stone. Queen Alexandra graciously visited the show on Tuesday morning, and spent a considerable time in admiring the flowers. So far as we could gather, on the opening day visitors were more numerous than ever, and it is evident that interest in horticulture is still on the upward

FORMAL GARDENS.

The formal gardens are not numerous, but by introducing a phase constitutes a most interesting feature.

In this department Messrs. Thomas Crowther and Sons, 282, North End Road, Fulham, S.W., have a display of old garden furniture, hammered iron gates, lead vases, temples and the like, some of which are highly ornamental and beautiful.

Messrs. Joseph Cheal and Sons, Crawley, have a formal garden in which a general garden scheme is adopted, shrub borders, rock-work and alpinas, Rhododendron banks and Azalea borders, Rose temple, arches, pergolas, paved ways, stone walls, Yew and other hedges being among the features introduced.

Messrs. Carter and Co., Raynes Park, S.W., have a particularly attractive garden, with Tudor summer-house in Horsecombe stone facing, stone dovecote, paved ways, dolphin fountain and basin, with Water Lilies, octagonal summer-house and other distinct features. The Rhododendron borders are a blaze of colour, the variety Pink Pearl making a fine show. The paved pathways, stone walls and roofs of the summer-houses are all suitably planted with Stonecrop, Houseleek and other plants. The Wistarias are very beautiful.

The formal garden arranged by Messrs. Wallace and Co., Colchester, is well conceived and admirably executed. The beautiful garden-house in Horsecombe stone, roofed with similar material, is delightful in its naturalness, the Norman style leaving nothing to be desired. In its way it is unique. The whole arrangement is encompassed by low stone walls, Box and other hedges, while stone steps and paved ways are as natural as could be. Within the walls are borderings of Flag Irises, which in their quiet tones beneath the shade of

trees are delightful in the extreme. Tulip borders are also a strong feature, while a well kept lawn adds to the quiet and beauty of the whole.

That arranged by Messrs. Pulham and Son, 71, Newman Street, W., comprises a sunk garden, with imposing fountain basin, seats, sandalwood pergola, balustrades, seats and the like. The "bird bath" is a feature here, and attracts much attention. In addition, there are grey borders

QUEEN ALEXANDRA AT THE OPENING OF THE SPRING SHOW
AT CHELSEA.

grade. In the pages that follow will be found a review of all that is best in this really wonderful exhibition. In the preparation of this Special Number we have been greatly assisted by the officials of the society, especially the Rev. W. Wilks, Mr. S. T. Wright and Mr. Frank Reader. Without their assistance it would have been impossible to have published an illustrated report of the show in so short a time.

SKETCH PLAN OF MESSRS. R. WALLACE AND CO.'S GARDEN HOUSE.

with others of scented shrubs, Lavender, Rosemary and the like. This exhibit is worthy of study.

Messrs. Piper, Bayswater and Barnes, have what they call a Wistaria garden, a circular arrangement, in which several flights of stone steps with their accompanying balustrades appear. The paved ways are lightly planted with vegetable life; the coping of the balustrades bedecked with an ample display of old, well-flowered examples of Wistaria, which are charmingly flowered. The whole idea is original and good, only requiring time to give it the requisite tone.

The Yokohama Nursery Company, Limited (Yokohama, London and New York), Craven House, Kingsway, have near the Lime Avenue a very pretty arrangement, into which all things Japanese enter—Japanese tea house, temple garden and temple lanterns, dwarfed trees, Wistarias and the like. The latter are very beautiful, well flowered and highly decorative.

ROCK GARDENS.

With the great International Show of a couple of years ago still fresh in the mind, it might savour of the absurd to say that rock gardening has never been seen in such excellence as that now on view at the Chelsea Hospital Grounds. At the same time it may be said with truth that on no former occasion has greater general excellence prevailed, or that better taste or skill has been displayed in its execution. In a word,

while the rock gardening star is obviously in the ascendant, there are also signs—the outcome of knowledge born of experience—of more studious and thoughtful work, and that phase of it in particular which, rendering such exhibits suggestive as a whole, also make repetitions of them possible in many gardens to-day. To have achieved so much is the highest aim of any exhibition; to bring to a high state of perfection is to excel. That, indeed, is the position of rock gardening to-day, and the two or three dozen exhibitors who have ranged their skill and displayed their taste side by side near the Embankment merit all praise.

Taking them in order of position, we first come upon a well-executed piece of work of 1,000 square feet or so arranged by Messrs. Waterer, Sons and Crisp, Bagshot and Twyford. Here prettily colonised and grouped we find many good things, more particularly the rare Phlox Douglasii, Arenaria juniperina, white Thymus subcitratus parviflora, Campanula Allionii with rich purple bells, Pentstemon Bridgesii, Lewisia oppositifolia, Mazus reptans (a true carpet covered with flowers not more than an inch high), many choice Primulas, alpine Phloxes and the like. The whole is executed in the Derbyshire limestone, and rendered pleasing and effective.

In the adjoining group from Messrs. Garnet and Co., Farley, near Leeds, the showier kinds prevail, masses of Phloxes, Aubrietias and the like, with Ourisia coccinea, Oxalis enneaphylla, Primula frondosa and others.

Bakers, Wolverhampton, are responsible for a well-conceived arrangement in which the larger rock groups are finely displayed. Some excellent crevice planting is also noted in this exhibit, with the dainty-leaved Japanese Maples playing a good part. The finer groups of things, and these rich in effect, are composed of Incarvillea brevipes, Tiarella unifoliata, Achillea rupestris, Saxifrages Codsall Cream and Miss Willmott, Cheiranthus Allionii, C. Warley Bronze (quite a distinct plant), Lithospermum intermedium and Daphne Cneorum.

That arranged by Messrs. Whitelegg and Page, Chislehurst, is particularly good and effective as well as spacious, a charmingly arranged miniature ravine constituting a great attraction. The sides of this will be found teeming with Ramondias, and higher up on rocky ledges the Edelweiss with Oxalis enneaphylla. In freer masses elsewhere will be found Phloxes, Saxifraga longifolia latifolia, Primula Unique Yarm variety, P. cockburniana, P. Unique Improved and P. cortusa villosa. Viola J. S. Martin (V. gracilis x V. bosniaca) is presenting a rich array of purple colour; while above all and in the wood beyond Irises and other plants are to be seen naturalised.

Messrs. T. S. Ware, Limited, Feltham, have done much excellent work with their allotted 600 square feet, and employ the Surrey sandstone to good effect. Their finer colour masses are made up of Aquilegia glandulosa (blue), Potentilla pyrenaica (rich golden), Tiarella cordifolia (cream), Viola pedata bicolor, Ramondias and Lithospermum Heavenly Blue. Among choice things will be noted Astilbe simplicifolia, Androsace primuloides, Haberleas and Lewisia Cotyledon, which is very charming. There will also be noticed a capital lot of hardy Cypripediums associated with Ferns in a cool and sheltered place. Altogether a highly attractive exhibit.

Mr. Maurice Prichard, Christchurch, has a well arranged rock, using Cheddar stone, of which there are many excellent specimens. Associated with this, the choice plants employed appear delightful in the extreme. Some of those to be sought out include Heeria elegans (of which there is a fine rosy mass), Silene pusilla (white, very dwarf), Arenaria verna plena, Oxalis enneaphylla rosea, Scutellaria indica japonica (blue), Gentiana verna, a fine lot of Primula Lissadell Hybrid, the rare fringed flowers of Schizocodon soldanelloides, Saxifraga cæsia præcox (a large-flowered early form), with choice masses of Mimulus radicans, Asperula athoea and the like. Cypripediums and dwarf Ferns are charmingly associated.

Adjoining this, Messrs. Barr and Sons, Covent Garden, W.C., have a capital piece of work, using the Cheddar limestone with good effect. At the moment of our inspection the brightest-coloured mass was seen in a grouping of Oxalis brasiliensis, while among other notable things the Peacock Iris (so-called), I. cristata, I. gracillipes, the rare Calochortus on sunny slopes, Viola pedata, Cheiranthus Allionii, C. mutabilis and Helichrysum bellidioides are all worth seeking. Dodecatheons, Sarracenias, Cypripediums, Primulas, Orchises and other suitable subjects associated with water are also pleasingly grouped.

On a bolder scale, by reason of employing larger rock masses and ascending to greater heights, Messrs. Pulham and Son, Broxbourne and Elsenham, have a picturesque piece of work in Derbyshire limestone, the interspersing paths paved with York stone slabs in irregular rectangular and crazy mosaic form. A bold waterfall

and streamlet are also effectively executed with suitable groupings of Ferns, Ceanothus, Epimediums, Gunnera, *Leiophyllum buxifolium*, *Meconopsis* and flowery masses of *Daphne Cneorum*.

Messrs. Wallace and Co., Colchester, have one of the largest stations and have arranged a highly meritorious exhibit, the design, as also the fine selected stone, attracting immediate attention. The plants here are almost bewildering in their variety by reason of the way that every crack, cranny or crevice is charged with its quota of alpine vegetation. Perched high will be found the Edelweiss, or jutting out from some rocky crevice such things as *Saxifraga cochlearis*, *S. Aizoon* or *S. cochlearis minor*. In freer groupings will be found *Onosmas*, *Viola pedata*, *Campanula Stevenii nana*, *Saxifraga Dr. Ramsay*, *S. Cotyledon* and the like. Then the spreading tufts of *Helichrysum bellidioides*, *Lithospermum*, and *Saxifraga Aizoon lutea* are worth seeking, while, anon, trails of the royal purple bells of *Edraianthus serpyllifolium major* will be found or tufts of *Iris gracillipes*. To make the exhibit comprehensive and complete, a pretty water-course has been formed with Primulas and Ferns in cool and shade. The association of shrub and rock is very good and quite worth noting.

On the opposite side of the Drive the Misses Hopkins, Shepperton-on-Thames, have a compact, prettily arranged exhibit of rock and alpine plants. Here will be found the alpine Phloxes, *Houstonias*, *Primula sikkimensis*, *Lithospermum Heavenly Blue*, many choice Saxifrages, the rich blue of the alpine Columbine, *Veronicas* and other good things.

The Guildford Hardy Plant Nursery has an excellent exhibit of rockwork, employing the Godalming sandstone with good effect. The stone is well fashioned and suited for the purpose, and, moreover, like all other sandstones, is sympathetic to plant-life. The firm is using many choice plants, some of the more conspicuous being *Sempervivum rubricundum*, *Cheiranthus mutabilis purpureus*, *Erpetion reniforme*, *Viola cucullata* (very fine), *Linum capitatum* (yellow), *Dianthus arvernensis* (a very choice alpine Pink), and the like. Showier things, as *Geum rivale* Leonard's variety, *Phlox Laphami* and *Heucheras*, are good, though the visitor must not omit *Onosmas*, *Oxalis enneaphylla*, *Parochetus communis*, and the charming effect which *Sempervivum Laggeri rubrum* is producing.

Mr. Clarence Elliott, Stevenage, has a nicely executed piece of work near the entrance, using in plenty the freer-flowering masses of things, while garnishing crack and cranny in all directions with the choicer morsels. Of those which cannot fail to appeal are *Helianthus rosmarinifolius* (white), *Oxalis enneaphylla rosea*, a fine mass of *Iris cristata*, *Pentstemon Davisonii*, *P. Riezli*, the pretty red-flowered *Dianthus squarrosa* and *Daphne Cneorum*. Shrubs and dwarf conifers are well placed amid finely selected Cheddar limestone.

Messrs. Kent and Brydon, Darlington, are employing Westmorland limestone with good effect, and associating with it *Primula bulleyana*, *Wahlenbergia serpyllifolia*, *Campanula Allionii*, *Ledum palustre*, *Trilliums* in splendid form, *Anemone sylvestris*, *Lithospermum graminifolium* and others. A miniature alpine meadow and bog garden are also features to be noted.

Mr. G. Reuthe, Keston, Kent, has also arranged a very delightful exhibit, delightful in the sense

of choice and rare, that ever appeals to the specialist. *Haberlea Ferdinandii-Coburgii* is here. It is finer and better than the old form. *Diplopappus pedunculatus* with violet flowers is rare and good; *Leontopodium lindarvianum* is a new species of Edelweiss, *Æthiopappus pulcherrimus* is a new alpine Thistle, while such as *Cypripediums* in variety, *Mertensia primuloides*, *Linum alpinum* (blue), *Gentians*, *Silene Hookeri*, *Sisyrinchium bermudianum* (fine blue mass) and *Primula Unique Yarm* variety will all be found in excellent condition. *Polygonum sphærostachyum* is in capital colour.

Very choice and good is the rockwork exhibit set up by Messrs. Tucker and Sons, Oxford, the firm employing the limestone of their own locality, which is both ornamental and good. This exhibit teems with choice things, and much time might be spent among them. Quite among the best are *Daphne alpina*, *Tanakaë radicans*, *Dianthus callizonus*, *Eryngium glaciale*, the true *Saxifraga valdensis* (which is also in flower), *Phlox Douglasii*, *Pratia Arenaria*, *Silene Hookeri*, *S. Veselesky* (a choice morsel in white), *Campanula Allionii*, *Daphne rupestris*, *Origanum Dictamnus*, with *Sempervivum rubricundum*, *S. arachnoideum rubrum* and *S. a. Laggeri*, are all worth seeking out.

The excellent exhibit arranged by Mr. J. Wood, Boston Spa, Yorkshire, represents as a whole a bit of Yorkshire fell land, the stone grey Yorkshire mountain limestone supporting its own moss and such British wildings as *Thymus Serpyllum*, *Sedum anglicum* and the like. These are augmented by the choicer alpine plants, Snapdragons, Forget-me-nots, *Potentillas*, Himalayan Poppies, Primulas, Saxifrages, Phloxes and other plants galore. The foreground of the arrangements in effect represents an alpine meadow, in which the choicest alpine plants, Primulas, Orchises and others are seen. Then, in the characteristic drift-like form in which this rock appears in Nature, we see Nature adorned, improved, as it were, by the master's art. Crevice and cranny and fissure are freely planted with

Ramondias, *Haberlea*, and Pyrenean Rockfoil (*Saxifraga longifolia*), whose great, hoary rosettes are very telling. In the driest places, *Sempervivum tomentosum* looks at its best, a great stretch of *Saxifraga Aizoon rosea* representing this plant finely. The pretty American Pine Barren (*Pyxidantha barbulata*), spangled with white flowers, is very charming. Anon, a Fern-planted gully is very cool-looking, while in plenty appear the choicest Primulas, with rivulet and tiny pond, while high above all, suggestive of distance, towered, as it were, the dwarf Pines, mirroring into life a very beautiful whole.

Another fine rock garden exhibit in the open is that of Messrs. Piper, Bayswater and Barnes, in which some thirty tons of selected Cheddar stone are employed. The general arrangement is that of raised mounds, with bays, ravines, and outcrop rock from turfy banks appearing in excellent fashion, the latter throwing into fuller relief the grey colour of the adjacent rocks. In every way it is an excellent piece of work. The general planting idea is that of free drifts, the natural bent of the rocks being duly considered. In this way such things as *Ramondias*, the great silvery Pyrenean Rockfoil, *Daphne Cneorum*, *Fabiana imbricata*, *Erinus*, *Stachys corsica*, *Phlox Laphami*, *Viola Golden Wave*, *Saxifraga Aizoon rosea*, *Pratia Arenaria* and *Scutellaria indica japonica* are seen. Of shrubs, *Cotoneaster congesta*, with *Pinus Cembra* above, are noticeable.

Under canvas there is also to be found many choice contributions to the alpine section. Here will be found Messrs. Bees, Limited, Liverpool, who are staging many choice plants of recent introduction. Of these *Roscoeia cautloides*, *Primula secundiflora*, *Oxalis adenophylla*, *Primula augustidens*, *P. japonica Garnett Bee*, *Potentilla fruticosa nana argentea*, *Lewisia Howellii* and, perhaps rarest of all, *Didissandria amabile*, a new Chinese alpine, with erect bell-shaped, creamy flowers on a short inflorescence above woolly *Ourisia*-like leaves. It is a remarkably pretty plant.

VIEW IN MESSRS. J. CATTIE AND CO.'S FORMAL GARDEN

ROCK GARDEN EXHIBITED BY MESSRS. R. WALLACE AND CO.

Messrs. Backhouse and Sons, York, have a table exhibit of alpine plants with rockwork in miniature. Here will be found not a few of the choicer plants—*Orchis foliosa*, *Trilliums*, *Primula secundiflora*, *Iris cristata*, *Ramondias*, *Gentiana verna*, *Ledums buxifolium* and *polifolium*, *Onosmas*, *Dendromecon rigidum*, *Edraianthus serpyllifolium major*, *Viola bosniaca*, *Oxalis enneaphylla* and other good plants. The exhibit is very daintily arranged.

The Lissadell *Primulas* from Sligo are very good, and choice hybrids and improvements abound. This is a very bright-looking lot.

In another direction Sir Everard Hambro, K.C.V.O., Hayes Place, Kent, has a fine setting of choice alpine plants amid plumes of the bolder *Saxifrages*, *S. Cotyledon* and *S. longifolia* forms more particularly. The white, faintly spotted plumes of these rise in their dozens, while constituting the groundwork are some of the choicest morsels of alpine vegetation; for example, *Erinacea pungens*, the finest example we have seen, full of dainty mauve Pea-shaped flowers on a tiny bush 6 inches high. It is a gem. *Dianthus alpinus*, *D. subacaulis*, *Primula Unique*, *Lewisia Howellii*, *Phyteuma comosum*, *Jankea Heldreichii*, *Haberleas*, the brilliant red-flowered *Pentstemon Davisonii*, *Heeria elegans*, *Silene Hookeri* and *Oxalis enneaphylla rosea* are some to be searched for.

Mr. H. Hemsley, Crawley, has a miscellaneous lot of alpine plants and a new race of alpine Snapdragons.

The Ightham Alpine Plant Nursery is staging *Violetta Slieve Donna*, a charming alpine, in which the firm are specialists.

ROSES.

The Chelsea Show without Roses would be shorn of much of its splendour, and although, generally speaking, we have seen finer individual blooms, yet one must admit that there are some very meritorious groups. Each recurring year accentuates our indebtedness to the Rambler and Polyantha sections for spectacular effect, and the grand pot-grown specimens show us what can be done with such Roses when suitably planted

outdoors. There is this much about the Chelsea Show: one is not painfully reminded of cramped space as was the case at the Temple, and exhibitors take full advantage of the improved conditions to display their productions to the best advantage. One or two glaring examples of clashing groups are evident, especially the placing of a huge mass of Zonal *Pelargoniums* between the two fine groups of Roses put up by Messrs. W. Paul and Son and Messrs. Hobbies, the glare of the *Pelargoniums* absolutely marring the beautiful effect of the Roses.

From a decorative point of view, nothing is better done than the group of Messrs. W. Cutbush and Sons, Highgate. This consists entirely of Rambler and Polyantha Roses. A splendid central column of Dorothy Perkins has a ground-

work of the gorgeous Polyantha *Erna Teschendorff*. Then there are mounds of Polyanthas of such sorts as *Jeanne d'Arc*, *Maman Turbat*, *Jessie*, *Mrs. Cutbush*, *Orleans*, and *Ellen Poulsen*, with a contrasting and well-flowered weeping Rose emerging from the mound. As a groundwork for the group there are some hundreds of plants of the dainty *Baby Tausendschön*, whose correct name is *Louise Walter*. We also noticed a good yellow Polyantha in *George Elgar*.

Messrs. W. Paul and Son, as usual, make a grand display. Their Ramblers are excellently flowered. In this group are some fine plants of *Sodenia*, a very valuable new Rambler, a few shades deeper than *Lady Gay*. *Kalmia* is also a pretty novelty, of a colour resembling the shrub whose name it bears. The new *White Tausendschön* is fine, also *Ethel*, a very dainty shade of pink. *Millicent*, a new Rambler, is a large double flower, but of rather a dull, uninteresting colour. Probably outdoors this dulness would disappear; if so, it will be a good addition. Of the large-flowered Hybrid Teas, *Mrs. Charles Hunter* is fine, also *Portia*, *Ophelia*, *J. L. Mock*, *Mrs. A. Hammond*, *Margaret*, *Farbenkönigin*, *Sunburst* (fine blooms, but very pale colour), *Mrs. W. Christie Miller*, *Entente Cordiale* and *Souv. de Gustave Prat*.

Messrs. George Paul and Son, Cheshunt, have put up a splendid group, but we have seen them show much better. One must not lose sight of the fact that the weather this spring has been exceptionally trying for pot Roses. Fine pillars of *American Pillar*, *Hiawatha*, *Lady Godiva* and *White Dorothy* are in this group, with splendid weepers such as *Minnehaha*, *Eisenach*, *Hiawatha*, and *Lady Blanche*, a very pure white. Standards of *King George V.*, *Leslie Holland*, *Niphetos*, and *Mme. J. Dupuy* are tastefully set among masses of the best Hybrid Teas. Among these we noted a fine batch of *Freda* (a grand pot Rose, with fine deep flowers), *Florence Pemberton*, *Magnolia* (wonderfully long buds), *Lady A. Stanley*, *Cherry Ripe*, *Othello* (a grand colour), *Mrs. A. R. Waddell*, *Lady Q. Ewart*, *Sunburst*

THE ROCK GARDEN SHOWN BY MESSRS. PULHAM AND SONS.

(here also very pale), Comte G. de Rochmauer (a fine new red), Rayon d'Or, Lady Pirrie, Rene Wilmart Urban, G. Grunerwald, G. C. Waud, Queen of Spain and many others.

Mr. George Prince, Longworth, has made a brave display with some excellent Ramblers, well flowered and of elegant shape. We noticed among the great variety of Ramblers a fine new sort named Chatillon, a Rose larger than Dorothy Perkins, and a most exquisite shade of light pink. Among the choice collection of cut blooms to be seen are some of the beautiful Mme. Edouard Herriot, a Rose whose wonderful colouring is sure to make it a popular favourite.

Messrs. G. Mount and Sons, Canterbury, are making a most sumptuous show—one of the best in the whole exhibition. A splendid background of Crimson Ramblers, such as Excelsa and Hiawatha, lend a very rich glow to the group, and this gives a fine array of colour and serves to bring out the snowy purity of the lovely Frau Karl Druschki, grown as the firm only can grow it under glass. Delightful masses of Sunburst, Richmond, Mrs. John Laing, Mrs. Sharman Crawford and the superb Mrs. George Sawyer are here seen in large quantities of really exhibition blooms. Other popular sorts well represented are Lady Pirrie, Melanie Soupert, Mrs. F. Straker, Lady Battersea, Mrs. Charles Hunter, Joseph Lowe, Liberty, and Mrs. A. R. Waddell, the whole edged by well-flowered dwarf pot plants of the Perpetual Crimson Rambler.

Messrs. Low and Co., Enfield, have a group of Roses with other subjects. The Roses are lightly arranged and are beautifully relieved with Acer Negundo variegata and variegated Euonymus. Some fine specimens of Excelsa, Dorothy Perkins, Blush Rambler and Tausendschön are exhibited as pillars, while well-flowered weepers of Hiawatha and Newport Fairy portray these fine sorts to perfection.

A very tastefully arranged group comes from Mr. Charles Turner, Slough. There are grand weepers of Dorothy Perkins, Lady Godiva, White Dorothy, Lady Gay and Ethel (a very lovely new Rambler all should plant), and there are also fine groups of Orleans Rose, Annie Müller, Jessie and Mrs. Cutbush, besides standard Teas and Hybrid Teas, the whole well toned down by Japanese Maples and Ferns. In the superb group of flowering shrubs we noted a fine specimen of Rosa Hugonis, doubtless grown outdoors, for it is now blossoming outside with us.

Strangely, among all the rock garden exhibits we did not see any Roses represented. Surely this was an omission, for there are some lovely gems, such as R. Malvi, now opening outdoors that make beautiful rock subjects.

Messrs. Hobbies, Limited, Dereham, put up two groups in their own inimitable style, with arched walks well clothed with Ramblers, and huge baskets of Polyantha Roses, many of them of the firm's own raising. Among these we saw Baby Elegance (a dear little Rose that will be largely wanted), Meadowsweet and Dewdrop, all being interesting additions to this popular class. Cut blooms of the leading Roses are tastefully arranged on stems, and these include the wonderful Mme. E. Herriot (of grand colouring), Countess of Shaftesbury, Willowmere, Sunburst, Lady Hillingdon, Mrs. A. Ward, Melanie Soupert, and Marquise de Sinety, altogether a delightful group. We must not forget to mention Effective, one of the most fragrant Roses, and a variety of better colour when grown outdoors.

Messrs. Burch, Peterborough, have a nice little lot, chiefly in show boxes, representing most of the leading varieties.

Messrs. Frank Cant and Co., Braiswick Nursery, Colchester, have one of the best arranged groups among the cut-flower exhibits. There is a delightful airiness in the whole display that cannot fail to charm visitors, and they should see this group before it fades. A beautiful new Rambler is Braiswick Charm, an almost perpetual variety, reminding one of Alberic Barbier, but the flowers are produced in larger clusters. It is also very sweet. Hercules is a most sweetly fragrant Hybrid Tea of merit, and of a lovely peach pink shade, and very double with cupped form. The Ramblers and short standard Roses are grand, the latter being of the variety Jessie, perhaps the best to grow in this form. The cut blooms are of special quality, some quite medal blooms, and of the best we noted Mrs. Walter Easlea (a fine, big flower, of delicious fragrance), George Dickson (grand), Mrs. Muir McKean, Mrs. A. Coxhead, Melody, Mrs. J. Welch, Lady Roberts, Juliet, &c.,

so freely, it will be possible for every grower to have new sorts, but unless hybridised it is doubtful if we shall obtain anything superior to those now grown, although there is always a chance of getting a good thing.

Messrs. R. J. Barnes and Son, Malvern, are showing American Pillar very finely, also Rayon d'Or as cut blooms. These are very good.

Messrs. A. Dickson and Sons, Newtownards, have some of their superb novelties. What a beauty is Chrissie McKellar, a glorious garden Rose of most enchanting tints! Red Letter Day is a grand mass of colour, and Killarney Brilliant splendid. One bloom of Mrs. Bryce Allan portrays a real gem, and for fragrance we know of nothing equal to it. A beautiful seedling reminds us of Marquise de Sinety and Sunburst, and will be warmly welcomed when sent out. Lady Dunleath, Carine, Irish Fireflame and Mrs. S. T. Wright are also grandly exhibited.

Messrs. B. R. Cant and Sons have a most delightful array, and one could almost imagine one were at the National Rose Show in July, so sumptuous

STRATIFIED LIMESTONE TASTEFULLY ARRANGED BY MESSRS. WHITELEGG AND PAGE.

while such lovely singles as Rosa sinica Anemone, Austrian Copper and Austrian Yellow are well represented.

Mr. E. J. Hicks, Twyford, has a very lovely group, in which we noted Mrs. E. Alford, a glorified Mme. Abel Chatenay. If this Rose grows well outdoors it may supersede that grand old Rose, but it will have to be of superior habit to do this. Lady Hillingdon, Mrs. G. Sawyer and Richmond are also fine, well set off by masses of Erna Teschendorff, Mme. E. Herriot and Orleans Rose.

Messrs. H. B. May and Sons, Edmonton, have Roses represented among their other subjects, these chiefly of the Rambler and Polyantha sections.

A new Polyantha is shown by Messrs. Munch and Haage. It is named Betsy Van Nes, and is said to be a red Mrs. W. H. Cutbush, and may probably supersede Jessie outside, although as shown we did not think much of it.

Mr. J. Crouch, Lower Edmonton, exhibited several seedling Polyanthas, but none of them superior to existing kinds. As these Roses seed

is the variety and superb the quality. The ramblers are splendidly flowered, and among these Goldfinch, American Pillar, Lady Godiva and Silver Moon are grand. Fine masses of Lady Reay, Mme. Edouard Herriot, Mme. A. Chatenay, Mrs. H. Stevens, Lady Hillingdon, Elizabeth, Molly Sharman Crawford, Austrian Copper, Duchess of Wellington, Claudius, St. Helena, &c., are also shown.

STOVE AND GREENHOUSE PLANTS.

Messrs. Sutton and Sons, Reading, excel on this occasion, staging a particularly handsome and attractive exhibit in the centre of the Large Tent. This exhibit consists of five large beds—four corner ones and a circular bed in the centre. As a whole this display makes a complete garden in itself. Their excellent strain of Cineraria stellata is one of the chief features, the colours and form of the flowers leaving nothing to be desired. The Schizanthuses are really superb.

the beautiful tones of colour represented in the Reading strain of these plants being charmingly varied and attractive. *Primula obconica* has never been better shown. The splendid quality of the plants and their beautiful and varied colours show how great has been their development. Of herbaceous *Calceolarias*, too much cannot well be said in praise of their beautiful condition

great show and of the name of Messrs. James Carter and Co., who have done so much for these flowers.

Groups 39, 40 and 43 in the Large Tent are represented by a series of beautiful plants from Messrs. Webb and Sons, Wordsley, Stourbridge. The plants are arranged in bold and striking form, rising to a height of about eight feet.

GROUP OF ROSES SHOWN BY MESSRS. WILLIAM PAUL, WALTHAM CROSS.

and their superb quality. Intermediate tones of colour are conspicuously good, and the plants are in the pink of condition. The centre bed is filled with *Clarkias* and an edging of *Cineraria* Reading Gem, the latter being a plant midway between the ordinary type and *C. stellata*. Stocks, *Nicotianas*, *Phloxes* and *Alonsoas* are also extremely well done, the plants representing strains of the highest excellence. A finish to this great exhibit of Ferns and other foliage plants makes one of the most attractive floral treats of the show. In another part of the Large Tent a beautiful group of *Clarkias* from this firm is a most commendable display.

Another very wonderful display is made by Messrs. James Carter and Co. On entering the Large Tent from the Embankment entrance the visitor is face to face with a wonderfully comprehensive and beautiful series of groups of greenhouse flowers. The plants are in the pink of condition, each subject being represented by flowers of the best, the colours also being very good. A great circular bank of *Cineraria stellata* and *Cactus* varieties, surmounted by a beautiful Palm, is the central feature of this wonderful display, and this is surrounded by other circular mounds of *Empress Elizabeth* (rose pink) and *White Queen* (pure white) Ten-week Stocks, *Gloxinias* (Invincible Prize), *Calceolarias* (Victoria Prize), *Petunias* (Queen of Roses, Purple Prince, Crimson King and White Pearl), *Schizanthus* (large-flowered Butterfly varieties), *Clarkia elegans* in exceptionally good form and remarkable for their very high colouring, large-flowered *Cinerarias* (Brilliant Prize), handsome *Streptocarpuses* and *Nemesias* (Orange Prince), which all combine to make an exhibit worthy of this

Herein are displayed beautiful examples of their superb strains of large-flowered *Cinerarias* and well-grown, freely flowered examples of the *stellata* and *Cactus* forms of these free-flowering plants. *Schizanthuses* are also well done, their compact hybrid *retusus* and *pinnatus* forms all being most attractive. Exhibition *Gloxinias* are well represented, and double-flowered *Begonias* are also in good form and condition. Not the least interesting are the representatives of *Primula obconica* and *P. malacoides*. Superb aptly describes the large-flowered herbaceous *Calceolarias*, the flowers being pleasingly varied. Hybrid *Streptocarpuses*, *Nemesia strumosa* and single *Clarkias* are a trio of beautiful plants deserving notice, and the choice seedling *Amaryllis* add a glorious piece of colouring to this fine exhibit. *Petunias*, both double and single flowered sorts, are attractive, as are the Ten-week Stocks. With *Grevillea*, robust Ferns and other foliage plants a pretty finish is given to this magnificent display.

Mr. Philip Ladds, Swanley Junction, Kent, displays a bright and highly attractive group of Zonal *Pelargoniums*, Ivy-leaved *Pelargoniums*, *Fuchsias*, *Heliotropes*, show and fancy *Pelargoniums* and magnificent *Hydrangeas*. *Mme. Moullière*, the new large white variety, has never been seen in better form and condition, and *Hortensis* is also well shown to contrast with the new white sort above mentioned. With Maidenhair and other Ferns a beautiful finish is given to this large group, which is most successfully set up in undulating fashion.

Zonal *Pelargoniums* as set up by Messrs. H. J. Jones' Nurseries, Limited, Ryecroft, Lewisham, S.E., are very fine. The large circular group, covering some 300 superficial feet, is filled with

well-grown plants carrying grand trusses of bloom in every tone of colour known in these plants. A few of the better sorts are *Pandora* (scarlet), *Will* (clear scarlet, very large pips), *Fred Gulliver*, *Mrs. Tom White*, *Harry*, *Fred Bunstead*, *Kitty*, *H. J. Jones*, *Harry Wood*, *Mrs. Fred Huggett*, *Mrs. Gulliver*, *Edgar A. Tickle* and a host of other good things, both double and single. The group is edged with Ferns and surmounted by a graceful Palm.

Messrs. James Veitch and Sons, Limited, Chelsea, fill a square with a series of five beds, with grass walks between. The central bed of circular form is filled with beautiful *Azaleas*. Here are to be seen grand plants smothered with delicate blossoms in many hues, all in the pink of condition. *Mme. Keller*, *Empress of India*, *Professor Wolters* (grand), *Mme. J. Vervæne*, *Charmer*, *Dr. Moore*, *Mme. Van den Cryssen*, *E. von Eeckhaute* and *Mme. Morreau*, among many other good varieties, make a glorious display. Two corner beds are filled with well-grown *Caladiums*, well coloured and in grand form. Noteworthy examples are *Le Resplendent*, *Lady Stafford Northcote*, *Prince of Wales*, *Mme. John Box*, *Triomphe de Comte*, *W. Rappard*, *Emperor Alexander III.*, *The Mikado* and many others. Stove and greenhouse plants proper fill the other two corner beds, and they comprise a wonderful assortment of beautiful plants. *Alocasia mortefontainensis*, *Gymnogramma schizophylla*, *Maranta insignis*, *Coccoloba pubescens*, *Phyllotanium Lindenii*, *Dieffenbachia Jenmanii*, *Croton Reidii*, *Alocasia argyrea*, *Sansevieria Laurentia*, *Dracæna goldieana*, *Ananassa sativa variegata*, *Cannas*, *Anthuriums* and a wonderful array of most beautiful subjects make this exhibit one of the features of this great show.

Amaryllis from Messrs. Ker and Sons, Aigburth Nursery, Liverpool, make an effective exhibit. The flowers are large and beautifully fresh, and comprise a large and varied assortment of colours. A few sorts worthy of special mention are *Sappho*, *Pink Gem*, *Fascination*, *Endymion*, *Crimson King*, *Orange Perfection* and *alba magna*. Interspersed with moss and Ferns the effect is pleasing.

Mr. J. J. Ward, Rocklands, Finchley, N., has a table group of herbaceous *Calceolarias*, the plants of which would have been in better condition a week or ten days hence. Some of the plants are in condition, and represent a good strain.

Magnificent *Schizanthuses* from Mr. Ernest G. Mocatta, Woburn Place, Addlestone, Surrey (gardener, Mr. Thomas Stevenson), are remarkable for their good quality. The plants are densely flowered, the quality of the blossoms of a very high order, and their colours are charmingly diversified. We have never seen better, and they are just at their best. There are thirty-eight plants in all, and a finish was given to this highly meritorious group with well-grown *Hydrangeas* and Maidenhair Ferns. The plants are described as *Schizanthus wisetonensis* *Excelsior* strain.

Hydrangea hortensis in beautiful variety is shown by Mr. Leopold Salomons, Norbury Park, Dorking. This is a very fine exhibit. The plants are at their best, and the colouring is superb. This table group is neatly finished with Ferns and *Panicum variegatum*.

Zonal *Pelargoniums*, both double and single flowered sorts, are shown by Messrs. Jarman and Co., Chard. This firm also stages the new *Centaureas*, *Viola cornuta* in variety and other subjects.

Handsome bunches of Zonal *Pelargoniums* are exhibited by Mr. Vincent Slade, Taunton. About

three dozen bunches are shown, embracing quite a number of the better sorts. Dublin, Vesta, Lady Wilson Todd and Naples are striking varieties.

A new Fern, *Adiantum gloriosum* Lemkesii, is shown by Messrs. Lemkes and Son, Alphen, Holland. This is a very beautiful plant, and is worthy of a place in all collections of stove and greenhouse plants.

A splendid group of *Streptocarpus* hybrids is put up by Mr. Henry B. Brandt, Capernor, Nutfield, Surrey (gardener, Mr. H. Cook). The flowers are large and their colours pleasingly diverse, and the group as a whole is much admired.

A pretty table group of show and fancy *Pelargoniums* is exhibited by Mr. A. P. Brandt, Bletchingley Castle, Surrey (gardener, Mr. J. W. Barks). This is a very pretty group. The plants are profusely flowered, and the quality of the flowers is superb.

A splendid table group of large dimensions is staged by Messrs. John Peed and Son, West Norwood, London, S.E. This comprises *Streptocarpaceus* in wonderfully pleasing variations of colour, and a capital lot of *Begonias*, also very varied in their colours and marking. The latter are especially noteworthy.

Calceolarias, herbaceous and otherwise, are well shown by Mr. A. H. Cole, Swanley, Kent. This is a very charming feature, and the strain a good one. A few fancy *Pelargoniums* are also shown by this grower.

A grand bank of herbaceous *Calceolarias* is exhibited by the Rev. H. Buckston, Derby (gardener, Mr. Shambrook). The plants are large, well-grown specimens, and are some of the very best in the whole show. Good culture is largely in evidence.

In the Long Tent, Messrs. James Veitch and Sons, Limited, Chelsea, have two table-end groups of Ferns, Fuchsias, *Spiræas*, *Primulas* in variety and a number of other useful plants, all of which are most interesting. The Fuchsias are trained in cordon form and are in splendid form and condition.

Messrs. H. Cannell and Sons, Eynsford, Kent, have an excellent exhibit of large and handsome bunches of Zonal *Pelargoniums* and a number of small plants of the better fancy *Pelargoniums*. The Zonals are very striking, *Lucania*, *Frogmore*, *Arabic*, *King Victor*, *Queenswood*, *Lady Roscoe*, *Princess of Wales* and *Mars* being some of the more noteworthy singles.

From the John Innes Horticultural Institution came a pretty table group of *Calceolaria* hybrids. To those anxious to improve these flowers there is much food for reflection to be found here.

Messrs. W. Cutbush and Son, Highgate and High Barnet, N., have a wonderfully interesting group, comprising miscellaneous plants. The arrangement of the different subjects leaves nothing to be desired—*Hydrangeas*, *Rhododendrons*, hardy *Azaleas* and *Cytisus* in variety, *Spiræa* and *Coleus* James Atfield (very noteworthy). There is much for all who are interested in these plants to profit by in this very charming group.

A grand lot of *Hippeastrums* (Veitch's hybrids) make a striking table group as set up by Messrs. James Veitch and Sons, Limited, Chelsea. They are a very fine lot, and are graded in colours. The quality is superb, colour, size and general condition impressing visitors in a very marked degree. From the same firm *Calceolaria Clibranii* and *Begonia Rex* in beautiful variety make a somewhat unique exhibit. The *Calceolarias* are

freely flowered, and are most striking. The *Rex Begonias* are novel and fascinating in a measure. The better sorts are *Morning Rise*, *Our Beauty*, *Frau G. Benary*, *His Majesty Rostoff*, *New Beauty*, *The Queen*, *Rex Rubrum*, *La France*, *Mrs. F. Sander*, *Ernst Benary*, *Masterpiece* and the extremely beautiful *Countess of Thellusson*. Two very large triangular groups in the Large Tent serve to display the mollis and Ghent *Azaleas*. This firm's exhibits are always a splendid feature of this great show, and this year they seem to have eclipsed all previous efforts. In the mollis section the plants are gloriously fine. The rich and beautiful colouring and the fragrance of this subject are most attrac-

tive. Ferns, and a variety of other subjects which combine to make a truly remarkable exhibit.

An extremely handsome group of *Schizanthus* is exhibited at the Embankment entrance to the Large Tent by Mr. Alfred J. Waley, Stone House, Reigate, Surrey (gardener, Mr. W. A. Dobson). Seldom have such remarkable specimens been seen, and the grower of this wonderful collection of plants deserves great praise. The plants are large, very freely flowered and the colours superb.

Mr. William Iceton, Putney, S.W., exhibits a splendid circular group of *Lily of the Valley* of a very improved form. This is superbly fine, and a source of great joy to many. Edged with

A CORNER OF MESSRS. SUTTON AND SONS' EXHIBIT, SHOWING FINE PLANTS OF *PRIMULA OBCONICA*.

ive. The better sorts are *Flambeau*, *Mme. Mayer*, *Comte de Quincey*, *J. C. van Thol*, *Imperial*, *Leon Vignes*, *Alphonse Lavallée* and a host of other good things. The Ghent *Azaleas* in the second group are quite fascinating, and it is a good thing to have the two sections divided as they were on this occasion. The better sorts are *coccinea speciosa*, *Fanny* (single), *Pucella* (single), *Daviesii*, *Pallas*, *Guelder Rose* and *occidentalis*.

A charming circular group of the lovely *Schizanthus* is exhibited by Mrs. V. A. Litkie, Clarefield, Pinkneys Green, Maidenhead (gardener, Mr. W. Hulbert). These are very large plants, flowering in the greatest profusion, in wonderful variety and in beautiful colourings. There are many truly grand things in this group, and the grower deserves much credit for his display.

Show, fancy and scented-leaved *Pelargoniums* are nicely shown by Messrs. Godfrey and Son, Exmouth, Devon. Interspersed with Ferns, the effect is quite pretty, and the varieties of the *Pelargoniums* of the best.

In a wonderfully comprehensive group round the Obelisk, Messrs. John Piper and Sons, Barnes, Surrey, exhibit a wonderful array of different subjects. *Azaleas Hinodegeri* and the *Silver Acer* cover the Obelisk, and round about are *Hydrangeas*, *Primula obconica*, pygmy Japanese

Maidenhair Ferns and *Dracæna Sanderæ*, the effect is very pleasing.

A pretty group of *Caladiums* is shown by Mr. L. R. Russell, Richmond. The plants are arranged in rather flat fashion and not so large as some others, but they are very fresh, clean and nicely coloured.

Indian *Azaleas* are shown by Mr. Charles Turner, Slough, in numerous plants trained in pyramidal form. They are an attractive lot, and take us back to the time when specimen *Azaleas* used to be shown at the Ghent flower exhibitions. This is a welcome feature of this great show.

Sarraceni are set up in natural fashion in a very attractive group by Mr. A. J. A. Bruce, Chorlton-cum-Hardy, Manchester. Pools and a mossy groundwork and rockwork to match make these plants at their best. With *Bamboos* and *Grasses* in association, we regard this exhibit as one of this firm's best efforts.

A miscellaneous group, comprising a variety of subjects, is set up by Messrs. Stuart Low and Co., Enfield. The *Bottle Brush Tree* (*Metrosideros floribunda*), *Azalea rosaflora*, *Hydrangea hortensis*, *Ceanothus Veitchii*, *Gerberas* and the new *Araucaria*, *Silver Queen*, are a few of the noteworthy subjects in this display.

A mixed group of a very commendable kind is staged by Messrs. H. B. May and Sons, Upper Edmonton. Heliotropes, Verbenas, Zonal Pelargoniums, Weeping Roses, Salvias, Lobelias, Fuchsias and numerous other plants all combine to make a beautiful exhibit.

A bold and massive-looking group of Caladiums comes from Messrs. John Peed and Son, West Norwood, S.E. The plants are well grown, but should have been raised somewhat from the ground-work of Ferns, &c. Some of the better plants are Mme. J. Box, Triomphe de Comte, Excellent, C. E. Dahle, George Gover and a wonderful series of plants with telling foliage.

Part of a large group set up by Mr. James Horlick, West Dean Park, Chichester (gardener, Mr. W. H. Smith), comprises a wonderful display of yellow Callas in the pink of condition. The species is *Calla Pentlandii*, and we doubt whether a finer lot of these plants has ever been seen.

Messrs. Barr and Sons, Covent Garden, W.C., make a fine exhibit of Japanese pygmy trees. There is a very charming assortment, the ages

Andrew Tweedie (cream), Countess of Dartmouth (cream, edged and flaked rose), Hon. Mrs. Ronald Greville (cream) and Hon. Mrs. Maurice Glyn (apricot).

Messrs. Blackmore and Langdon, Twerton-on-Avon, Bath, set up an inimitable group of tuberous-rooted Begonias in quality of the most superb description. Seldom is the British public treated to such a wonderful representation of these beautiful flowers. Without a single exception the blooms are of the highest quality, and represent the last word in these gorgeous flowers. Noteworthy sorts are Princess Victoria (salmon pink), Lord Methuen (bright scarlet), Rose Superbe (pale rose), Lady Carew (deep rose), Violet Langdon (flesh pink), Irene Gambling (orange), Lady Cromer, Mrs. James Reid (lovely pink), Empress Marie (white) and Mrs. James Douglas (yellow). These are just a few of the wonderful things in this group, and gives this firm the high position they have won with these plants.

A charming bank of tuberous Begonias, rising to a considerable height at the back, is staged

although they may not be able to produce flowers at so early a date. As is well known, some acres of glass are devoted to Sweet Peas for market purposes, and from about mid-April one sees blooms of varying quality in the florists' shops. The various Sweet Pea specialists likewise devote a considerable amount of glass to this crop, and in doing so they benefit materially by being enabled to exhibit long before the natural period of blooming, while they also are able to ensure a more or less good crop of seed of the more valuable varieties.

Messrs. Dobbie and Co. of Edinburgh were among the first to realise the importance of indoor culture, and after several tests in the ordinary houses originally installed at Mark's Tey, the firm some three or four years ago erected special large, airy houses solely for Sweet Peas. To say that these houses have justified themselves is hardly sufficient. Not only is the firm among the first to exhibit each season, but the quality is rarely matched and never surpassed. On this occasion the firm cover 150 square feet, the vases arranged in three tiers and backed by the well-known black velvet screen. It is impossible for us to attempt to enumerate anything like the whole of the varieties shown, so we must be content to mention the most new and notable. An outstanding novelty is Dobbie's Orange, a gorgeous orange salmon of great size. A veritable flame. Royal Purple is assuredly one of the great things for 1915, a giant purple self different to anything we have had before, even in the days of the old grandifloras. It may not be everyone's colour, but still it is a coming variety. Alfred Watkins is a peculiar greyish lavender of a very even shade. Frilled Pink, another novelty of great promise, impresses one by its intense frilliness, while its colour is a clear bright pink. It is a most advanced type of Spencer. Duchess of Portland, a delightful cream pink of great size, is another new-comer, while Norma is a superb orange salmon cerise of huge proportions. Several seedlings, including a white and an intense orange, we noted, while among the standard sorts May Campbell, Thomas Stevenson (nearly all fours this), Lady Miller, King White, New Marquis, and Edrom Beauty are in strong evidence.

Messrs. E. W. King and Co., Coggeshall, make an effective display, the stand being tastefully decorated with Smilax and other foliage. Kathleen makes a brilliant patch of colour, while James Box impresses one by the doubling of its flowers. This is certainly one of the leaders in the salmon section. Anglian Blush is a novelty of promise; Anglian Cream Duplex is striking by its strong colour and tendency to double; and Morning Mist may be termed a Walter P. Wright on a cream ground. Other notable varieties are Anglian Fairy, Anglian Royalty, Anglian White and Queen Mary. Several of the varieties shown were cut from the open ground.

A very clean exhibit is that by Mr. J. Stevenson, Wimborne, and while the number of varieties is not extensive, several telling blocks, including Thomas Stevenson, Bertrand Deal, Prince George, Agricola, R. F. Felton, and Hercules we noted. These for the most part are set up in Bamboo pillars, the length of stem in some instances being very great.

Mr. James Box, Lindfield, differs from the other exhibitors by setting up a group of plants in the Large Tent; as all the plants are in 6-inch pots, it naturally follows that the flowers are not over-large. Nevertheless, they are interesting, and

SOME OF THE BEGONIAS SHOWN BY MESSRS. BLACKMORE AND LANGDON.

of the trees ranging up to 200 years old. Most of the trees are in excellent form and condition, showing evidence of considerable care and attention.

BEGONIAS.

Messrs. Thomas Ware and Co., Feltham, Middlesex, have a grand table group of their magnificent tuberous-rooted Begonias, in which large and handsome double-flowered varieties predominate. Marvellous advance must be chronicled with these gorgeous flowers, form and colouring now being all that the connoisseur could well desire. The plants are in excellent condition for so early in the year, flowering freely and carrying superb examples of cultural skill. Among the more noteworthy additions this season are King George V., a very large and handsome flower of good form and rich salmon colour; and Duchess of Marlborough, a lovely rich salmon pink of high quality. Other good things worthy of special notice are Gladys Valentine (pale salmon), Mrs. Maurice Pope (salmon rose), Mrs.

by Mr. A. Ll. Gwillim, Sidcup, Kent. These are all double-flowered sorts and represent many of the better-known varieties. Lady Cromer, Mrs. J. C. Gwillim, Miss Ada Britten, Sidcup Beauty and Mrs. H. Harris are especially noteworthy sorts.

SWEET PEAS.

It is but a few years since Sweet Peas first made their appearance at the Royal Horticultural Society's spring shows, and while the quality was not actually impressive, the flowers, nevertheless, caused a mild commotion. Nowadays, however, we not only look for Sweet Peas in May, but we expect quality equal to the best that the month of July will produce, and, what is more, we get it. The advance in the art of Sweet Pea growing under glass is little short of miraculous, and those who are familiar with the blooms produced in this country and the United States, the home of Sweet Pea forcing, assure us that the home growers more than hold their own,

demonstrate that Sweet Peas can be grown even in small pots. A great number of varieties are staged.

Messrs. S. Bide and Sons, Farnham, elaborately stage a fine collection. All the varieties are set up in glass vases, under a white-roofed erection, the effect being distinctly good. The flowers are extremely strong, and several telling novelties are noted. Ruth Bide is an intense rosy salmon, much brighter than A. A. Fabius. Phyllis Bide should give the much-talked-of Robert Sydenham a severe tussle. Bide's Cream is deep in colour, while among other new varieties, Climax (deep rose), King Mauve, Blue King, King White and Phœbus stand out strongly. A really very striking exhibit.

An excellent display is that made by Messrs. Robert Sydenham, Limited, Birmingham, and here on this stand one is able to see that wonderful orange named after the late lamented Robert Sydenham. Grand blocks of Barbara, Inspector, Princess Mary, Thomas Stevenson, Maud Holmes, Margaret Atlee, Lilian and Lady Evelyn Eyre are all splendidly shown.

A small stand is put up by Messrs. R. H. Bath, Limited, Wisbech. The firm's new orange named Glow stands out strongly, while some excellent vases of Hercules, King White, La Belle Sauvage, King Manoel, James Box, Mrs. J. C. House, Afterglow, Florence Wright Spencer and Thomas Stevenson are among the remainder that are on view.

A very telling exhibit is that of Messrs. Sutton and Sons, Reading. Backed by a polished mahogany series of archways, the flowers are arranged in three semi-circular bays. Elaborate tall vase-holders of polished nickel are carrying the flowers that fill the spaces between the semi-circles. Robert Sydenham is well shown, while a superb new cream, unnamed, is also in evidence. Among others, Barbara, Royal Rose, Maud Holmes, Mrs. J. C. House, Thomas Stevenson, Margaret Atlee, Decorator, R. F. Felton, Inspector and Florence Wright Spencer all stand out prominently in this effective exhibit.

Taken collectively, the Sweet Peas are by no means the least important section in the exhibition, and the firms exhibiting deserve full credit for their efforts. Had more space been available, we believe more extensive exhibits could have been set up; but in conformity with the idea of the Royal Horticultural Society, exhibitors have refrained from duplicating the varieties, with the result that the visitors are able to view a large number of varieties on a comparatively small amount of space.

FERNS.

At the south-eastern entrance to the Large Tent, Messrs. H. B. May and Son, Limited, Upper Edmonton, N., have set up one of their renowned groups of choice Ferns. This is of a most representative character, and comprises many specimens of remarkable beauty. There are some seven hundred species and varieties, which will give the reader some idea of the comprehensive display made by this wonderful group. Specially noteworthy examples are *Adiantum grossum*, a novelty in Maidenhair Ferns; *Davallia solida superba*, one of the very finest specimens; *Pteris flabellata plumosa*, a feathered kind of the old South African species; and *Platycerium Cordreya*, a wonderful development in the Elk-horn Ferns. Of standard Ferns, *Nephrolepis Willmottæ* is quite the newest type of the Lace Fern. In the

hardy section a novelty worthy of note is *Polystichum gracillimum Drueryi*. This section is well represented, and to Fern-lovers should prove a source of considerable interest.

A pretty little table group of Ferns and cactaceous plants is shown by Mr. H. N. Ellison, West Bromwich. The Stag's-horn Fern (*Platycerium grande*) is very fine, and there are other interesting plants. Cacti are shown in great variety in small pots.

HERBACEOUS & BULBOUS PLANTS.

This department is well represented, many leading firms bringing of their best.

In the group from Messrs. Barr and Sons, Covent Garden, W.C., will be found a choice collection of *Ixias* and *Sparaxis*; of the latter Scarlet Gem is a notable sort. Then in *Iris susiana*, *Eremuri*, *Olearia*, *Cytisus*, *Androsace*, *Gentian* and *Oriental Poppy* the searcher after meritorious subjects has a wide choice. In this group, too, the green-

Messrs. George Jackman and Sons, Woking, have many showy things in *Delphinium*, *Pæony*, *Lily*, *Spiræa*, *Geum* Mrs. Bradshaw, the early *Gladioli*, *Oxalis enneaphylla* and other choice things. *Delphiniums* *Capri* and *King of Delphiniums* are very good.

Messrs. Wallace and Co., Colchester, have an amazing group near the centre of the Large Tent, the collection particularly rich in Japanese *Acers*, *Lilies*, *Irises*, *Ixias*, hardy *Orchids*, *Eremuri*, *Primula* and the like. Of the *Lilies*, such as *Martagon dalmaticum*, *myriophyllum*, *Krameri*, *venustum* and *macranthum* are all worthy of note, while the towering spikes of *Eremuri* will appeal to all.

Messrs. G. and A. Clark, Limited, Dover, are showing finely *Iris*, *Polyanthus* Cloth of Gold, *Incarvilleas*, *Pyrethrums*, *Geum* Mrs. Bradshaw and other showy flowers.

Messrs. George Bunyard and Co., Maidstone, have a fine display of hardy flowers, notably *Thalictrum dipterocarpum*, *Astilbe Ceres*, *Delphinium Cymbeline*, *Iris King of Iris*, *Eremuri*,

HERBACEOUS CALCEOLARIAS EXHIBITED BY MESSRS. E. WEBB AND SONS.

flowered *Ixia viridiflora* is very beautiful, and appeals by reason of its rare colour and quaintness. It is charming in the cut state.

Mr. James Box, Lindfield Nurseries, Hayward's Heath, is staging admirably *Primula*, *Spiræa*, *Pæony*, *Anemone*, *Incarvillea brevipes* and choice *Liliums*. Of these latter *L. Grayii* and *L. canadense* are very beautiful. A group of hardy *Cypripediums* adds interest to the whole.

Mr. Amos Perry, Enfield, is making a fine central display of Tree *Pæonies*, while about and around are collections of *Poppies*, *Irises*, hybrids of the *Regelio-cyclus* and *Korolkowi* groups and many interesting species. A new white *Poppy* here is very beautiful, if less sumptuous than some, while the new white *Marguerite*, *Chrysanthemum Leucanthemum fl.-pl.*, is interesting and good.

Mr. G. Reuthe, Keston, Kent, has an excellent group of things—*Crinodendron Hookeri*, *Rhododendrons* of the choicest sorts in bold array, *Irises* of the *Oncocyclus* and *Regelio-cyclus* sets, with *Primula*, *Celmisia*, *Olearia*, *Cypripedium* and other choice subjects. The *Rhododendrons* and *alpines* in this group are very beautiful.

Pyrethrum Mary Kelway, *Rhododendron* Pink Pearl, with *Ghent Azaleas* and other flowers.

Messrs. Phillips and Taylor, Bracknell, have a fine show of *Primulas*, *Auriculas*, *Anchusa*, *Iris*, *alpine* and other *Phloxes*, *Astilbe* Peach Blossom and the like.

Messrs. Gunn and Sons, Olton, Warwickshire are displaying *Phloxes* Frau A. Buchner, Elizabeth Campbell, Lord Curzon, Princess Royal and other fine kinds in their usual good form.

Messrs. Cutbush and Sons, Highgate, N., have some effective groups of *Incarvillea*, *Gaillardias*, *Iris lævigata*, *Primula japonica splendens* (a particularly good form) and *Liliums* in variety. A very pretty group.

Messrs. Ware, Feltham, have some excellent *Pæonies*, *Primulas*, *Pyrethrums*, with a good display of *Eremuri* and *Poppies*.

Messrs. Gibson and Co., Bedale, Yorks, have an effective lot of *Thermopsis fabacea*, *Astilbe* Queen Alexandra, *Lupines* and other showy flowers.

Messrs. Kelway and Sons, Langport, have some of their finer *Delphiniums*, Remarkable, Lemberg

and James William Kelway, *Pyrethrum Princess of Wales*, *P. Edward VII.* and *P. Lord Milner*, all of which are excellent.

Messrs. James Cocker and Sons, Aberdeen, have goodly groups of *Trollius Yellow Prince*, *Anemone alpina* and *A. sulphurea*. The *Trollius* in this group are most attractive.

Messrs. B. Ladhams, Shirley, Southampton, are showing *Erigeron hybridum* B. Ladhams, *Trollius excelsis*, *Campanula glomerata* Mauve Queen and *Thalictrum aquilegifolium superbum* in capital form.

Messrs. Lilley, Guernsey, have an exhibit entirely composed of the graceful *Ixias*, early *Gladioli*, *Calochorti*, *Watsonias*, Peacock Irises and other unusual flowers.

Messrs. Blackmore and Langdon, Bath, are showing in capital style *Delphiniums* Mrs. J. S. Brunton, Walter T. Ware, Queen Wilhelmina, Eva, Capri, Moerheimi and others.

Messrs. Rich and Co., Bath, are showing *Pyrethrum Queen Mary*, *P. Kleinholtz*, *P. Louisa*

sorts, to which section this grower chiefly devotes himself. A few of the more dainty *Violettas* at this early period are *Rock Orange* (a lovely rich yellow), *Rock Lemon* (lemon yellow, very sweet scented), *Eileen* (a dainty mauve blue with a grand habit), *Cecilia* (a deeper mauve blue), *Mollie* (rich yellow of charming form) and *Rock Blue* (a deep tone of purplish blue). These are charming plants for the rock garden.

Violas from Messrs. Seagrave, Sheffield, make an interesting display. A large number of sprays of blooms are set up in the orthodox fashion, embracing such sorts as *Marion M. Roberts*, *Dunbryan*, *Kathleen Howard*, *Kathleen Immortalité*, *Moseley Perfection* and *A. S. Frater*. A few lifted plants in front complete this exhibit.

Mr. George Underwood, Leicester, has a number of porcelain pans filled with very sweet and clean *Violas* set up on white stands—*Agnes Kay*, *Gladys Finlay*, *Bessie*, *Admiral of the Blues*, *Darkey*, *Moseley Perfection*, *A. S. Frater*, *Maggie Mott* and

CARNATIONS.

One of the many exhibits of Messrs. William Cutbush and Son, Highgate and High Barnet, is a very handsome group of Perpetual-flowering and Malmaison Carnations. These flowers are set up in this firm's inimitable manner in handsome vases, stands, &c., with a groundwork of plants in full blossom, interspersed among which are Ferns, &c., for effect. The more noteworthy varieties of the Perpetual-flowering section are *Mrs. McKinnon* (scarlet), the new *Lady Ingestre* (salmon pink), *Mrs. Fullerton* (mauve and cerise), *White Wonder* (white), *Mrs. Raphael* (salmon), *Marmion* (pink and white), *Crimson Glow* (a glowing crimson) and *Mrs. Tatton* (pink ground, flaked white). Of the Malmaison type the better examples are *Mercia* (salmon), *Lady Coventry* (scarlet), *Princess of Wales* (in grand form, pink), *Baldwin* (rose), *Nell Gwynn* (white) and the type. These all combine to make a most attractive display.

Carnations are now an inseparable adjunct of nearly every flower show. Ever since America sent us the Perpetual-flowering type they seem to have been growing in public favour. There are many enthusiastic growers who prophesy a much greater future, more especially since it has become known that nearly every variety does well as a summer bedding plant. The Perpetual Flowering Carnation Society has done much to bring the flower into prominence, and it goes without saying that such a huge show as that of Chelsea, with its enormous attendance, will do much to carry on the good work if the leading growers exert themselves to put their best before the public. That they have done this will be, we think, the unanimous verdict when the beautiful groups are visited. Some are arranged in the very large tent, where there is only the bare ground to start with; some in the smaller flower tent, where there is the usual orthodox staging. There are large groups, such as Mr. Engelmann's and Messrs. Stuart Low and Co.'s, and small ones, like those of Mr. E. J. Wootten and Mr. James Douglas. It will be, perhaps, more convenient for reference and for finding them if we take the different exhibitors according to the tent in which they are placed and touch upon some of the more interesting kinds which, we think, visitors will like to see.

Beginning with the Large Tent, and taking the different exhibitors in alphabetical order, we first of all come to Messrs. R. H. Bath of Wisbech, who among their many Tulips have one solitary Carnation; but one, if it is important enough, makes up for many. Premier, which we would describe as a deep primrose in colour, is a step on the road to the deep lemon yellow Perpetual, which now seems to be one desideratum of the Perpetual type.

Mr. Bertie E. Bell from Guernsey is famous for the way he grows Coronation, a striking rose, and British Triumph, a well-known and meritorious crimson.

On another table Mr. H. Burnett, who also hails from the same famous land of glass and flowers, has a grand exhibit, in which *Marmion*, the "Painted Lady" Malmaison; *R. F. Felton*, the large, deep pink; and *Mrs. Raphael*, the red Malmaison-looking Perpetual—or, should we say, the Perpetual red Malmaison?—are conspicuous.

In about the centre of the eastern side no one will fail to notice an exhibit quite apart from all the others in the style of its flowers. They are rounder, flatter-petalled, smoother-edged and, seemingly, of greater substance. Two lines from

MAY-FLOWERING TULIPS ARTISTICALLY STAGED BY MESSRS. BARR AND SONS.

Delbassale, *Geum Mrs. Bradshaw* and the pink-flowered *Pyrethrum Hamlet*, all in capital style.

Messrs. Frederick Smith and Co., Woodbridge, Suffolk, have some fine *Eremuri*, *Lupines*, *Heuchera* Edge Hall variety, *Astilbes* and other good things.

VIOLAS AND PANSIES.

An attractive exhibit of bedding *Violas* and a few of the better *Violettas* is set up by Mr. Howard H. Crane, Woodview, Highgate, N. The blooms are arranged in green-painted saucers of wet sand, and give a very good idea of the beauty of these free-flowering subjects. Some of the more noteworthy *Violas* are *Mrs. B. Eric Smith* (rich orange yellow), *Liuggi* (pale yellow, very large), *Swan* (white), *Cygnets* (lovely creamy white), *A. S. Frater* (white, edged blue), *Royal Purple* (effective royal purple), *Bridal Morn* (pale mauve blue), *Moseley Perfection* (enormous rich yellow) and a host of other good bedding

a number of beautiful sorts too numerous to mention.

Messrs. Gunn and Sons, Olton, Warwickshire, show numerous large baskets of *Moseley Perfection Viola*, seven baskets of *Viola cornuta purpurea*, and a few pans of *V. gracilis*. These are arranged as a table group with *Roses* as a background, and make an effective display.

Pansies and *Violas* are set up in pans by Messrs. Carter Page and Co., London Wall, E.C., and include such *Violas* as *Kathleen*, *Pembroke*, *Redbraes Yellow*, *Mrs. E. A. Cade*, *Virgin White*, *G. C. Murray*, *Olive Blyth*, *Lark*, *James Pilling* and a number of good fancy *Pansies*.

Pansies and *Violas* in pans make a pleasing feature of Messrs. Dobbie and Co.'s (Edinburgh) group. These are growing plants, and give a proper idea of the growth of each sort. Of the *Violas*, *Redbraes Bronze*, *Mrs. Chichester*, *Edina*, *Mrs. Norris*, *Elye*, *Fred Williams* and *Crimson Bedder* are shown. *Dobbie's Gem* is a fine bedding fancy *Pansy*.

an old and, we believe, rare poem on a British garden come to us:

"Managed well by skilful florist's care,
Preserve their compass truly circular."

This may have been written in the days of the short, fat, bursting calyces; but it is appropriate to describe the beautiful, long-calyxed Jean Douglas (Geranium scarlet), Annie Laurie (blush pink), Bookham Yellow (the upstanding yellow, The Ameer (glowing crimson) and Mrs. Andrew Brotherston (white, very thickly splashed mole-armine). Mr. Douglas also has some old-fashioned Pinks. One, Aviator, will appeal to many, and is a contrast to those which are shown by Mr. C. H. Herbert, whose little group is to be seen not far away.

Messrs. Stuart Low and Co. have a particularly interesting lot here, as well as a second group in the two-acre tent—Satin Robe (an improved Winsor), Gorgeous (the wonderful cherry carmine which is so good under electric light) and a series of perpetual Malmaison seedlings, one of which might almost be a replica of the famous Princess of Wales.

No one must miss the highly interesting series of new American novelties which Mr. W. Wells has. The following three were first distributed in England this spring: Champion (scarlet), Philadelphia (pink) and Peerless (cerise). Once we were dependent on Uncle Sam for all our good things, but it is not so now, as an enquiry at the different exhibits will soon convince the reader. Mr. E. J. Wootten, for example, has Lucifer (scarlet), Mousmé (heliotrope and scarlet) and Lord Chancellor (a free, small, deep crimson), all made on the premises at Eastleigh, England. And he is but one of many where the same thing may be found.

Now for the Large Tent where there is no conventional staging, but where each group is after the exhibitor's own fancy.

Messrs. Allwood Brothers have a palmy exhibit with the famous rose Mary Allwood and the scented white Wivelsfield White conspicuous, not to mention some Malmaison-looking seedlings, e.g., Exquisite (pale salmon), all, we believe, perpetual.

Pot plants are a change, and visitors will find such a one in the group of Messrs. William Cutbush and Son in one of the centre spaces. Lady Ingestre, Mercia and Lady Coventry should be noted here.

A second pot group, which we are taking out of alphabetical order, is that of Messrs. Young and Co., Cheltenham. From the advertisement in the wonderful Royal Horticultural Society's Book of the Show one may expect to see Mr. Taudevin beside his flowers. He will be there all right, or, like the Allwoods, Engelmann, Dutton, Cook, Burnett and others, he is always there or thereabouts. He will point out the beauties of the summer-flowering Cecilia or the deep rose pink May-Day-looking Lady Nunburnholme, or the dark clove Duchess of Devonshire—a fine trio. When in our wanderings among the maze of bright beds we came upon Mr. A. F. Dutton's display, we instantly thought of the Bohemian Girl who "dwelt in marble halls." How nice to have been her on a hot day! Mr. Dutton looked so cool, and his exhibit looked so cool—what mattered it now that he had searched half London before he found what he wanted. "Go and see," to slightly alter a familiar saying, and when you do, be sure to bury your nose in the white Niagara and make particular enquiries for Chelsea, an

exquisite rose and white fancy or old-fashioned Picotee, to our mind about the best of its class. It is an Ar variety.

In one of the Hospital end corners will be found the superb display of that very go-ahead raiser and grower, Mr. Engelmann. Plenty of beauties, old and new, may be seen in his collection. Queen Alexandra, the delightful pink sport of Scarlet Glow, the bright scarlet sport of Carola; Circe, a study in mauve and cerise; and Bella, a small pale apricot-coloured "Painted Lady." Three hundred and fifty years ago at least the Carnation "had been made pleasant and sweet by the wits of man" (Turner, c. 1550). Man is still making it pleasant, and we hope is going to make it sweeter. We want more scent to-day.

TULIPS.

Tulips are very much to the front. There are sixteen groups mentioned in the list of flower exhibitors, to say nothing of those others, such as Carter's, where the flower is only a sort of incident in a larger scheme or group. If the Carnation is "the Summer's Glory," "the Tulip is the Pride of Spring." Can it be otherwise when we see the splendid magnificence of this marvellous flower? Last year Messrs. John Jefferies and Son brought one of their Cotswold hills and covered it with bloom. The seed sown has borne fruit, and visitors will find to-day a Taplow hill (Messrs. Barr and Sons), a Wisbech hill (Messrs. R. H. Bath) and a Kidderminster hill (Messrs. Cartwright and Goodwin). Each is covered with fine bloom. Zulu, Remembrance and the splendid Professor Rauwenhoff on the latter; Louis XIV., Morales and Ellen Willmott on the first; and Petrus Hondius and King George V. on the Wisbech one, must all be sought out and found. Each is good of its kind. We suppose because "the powers that be" wanted another novelty, the hill pioneers (Messrs. Jefferies) are relegated to a side position. They have a pleasing array, in which Ouida, James Wild (a good bizarre) and the new Van der Heede may be noted.

Messrs. Dobbies', as usual, are magnificent, large and clean. Visitors will appreciate their bold masses of Velvet King, Sunset and Margaret (Gretchen).

The most novel display of Tulips in the whole show is that of the bedding arrangement of a firm which hails from Manchester—Messrs. Dickson and Robinson.

Mr. Compson has given us a bit of the real thing. He has made up real-looking beds, and to those who want ideas we say, unhesitatingly, pay this exhibit a visit. The maroon King Harold, with an undergrowth of Funkia Sieboldii fol. var., the scarlet Gesneriana major among the Columbines and the quiet, refined bed of Ph. de Communes, Turenne and La Tristesse, filled in with pale mauve Phlox divaricata, are samples of an exceedingly instructive and well-thought-out idea.

All the above-mentioned are to be found in the Large Tent.

In the Table Tent we find more conventional groups.

Mr. Watts of St. Asaph has some fine, well-grown flowers, Baronne de la Tonnaye, Ouida and Orange Globe being very good.

Messrs. R. Wallace and Co. stage for the most part Cottage varieties. They make a welcome change from so much "Darwin," for a considerable proportion of the public, we feel, appreciate the more pointed and less stiff types. Pride of

Inglescombe, Innovation and The Fawn are examples.

Messrs. Waterer and Crisp, Messrs. Sutton and Sons, Messrs. Hogg and Robertson, Messrs. R. and G. Cuthbert and Sons and Messrs. Dicksons of Belfast all have fine, large displays, and we wish we could individualise the varieties on each stand in detail. May Blossom, La Singulière, Plutarchus, Zomerschoon, Ascanio, Giant, Isabella, Panorama and White Queen (as seen at Messrs. Cuthbert's) are all worthy of mention.

We would like to call special attention to Mr. C. Bourne's group, and also to that of Mr. Dawkins's. This is the latter gentleman's first appearance "on his own" at Chelsea, and we take the opportunity of wishing him *bon voyage*. May the shade of Davey rest upon him, and may he find a public as willing to buy as the older florist did a century ago when the *cheapest* late Tulip was priced at 2s. each (1823). Rises take place now. Mr. Bourne has The Bishop, the bluest purple Tulip. Its jump in price is one of the mild sensations of the present.

We close this short account of what is on view in the way of Tulips with the assurance that time spent among them will be so much *well* spent, for, as Mr. Jacob says, "A garden to-day is not a garden unless it has some Tulips in it."

The Royal National Tulip Society is holding its annual show of florist and other varieties in the Council Tent. The love for these aristocrats of the floral world is an educated one. The taste for these sun-loving flowers is an exceedingly refined one. Hence they are not everybody's choice, but to their devotees they spell enjoyment and charm. Mr. C. W. Needham and Mr. A. D. Hall are giants here.

TREES AND SHRUBS.

This is a grand season for Rhododendrons and Azaleas, and these shrubs are among the most floriferous in the exhibition, while the highly coloured foliage of the Acers almost vies with the flowers in the brightness of the effect. For the purpose of convenience we will deal first of all with the trees and shrubs shown in the Large Tent.

Messrs. James Veitch and Sons, Chelsea, have a beautiful collection of flowering shrubs, in which Rhododendron Pink Pearl may be seen in the height of perfection. The brilliant red Rhododendron Doncaster is also good, while Philadelphus Virginal, Rosa Hugonis, the pink-flowered Cytisus Dallimorei, Viburnums, Clematises and Hydrangeas are shown in wonderful profusion.

Some choice Rhododendrons are shown by Mr. G. Reuthe, Keston, such as Dalhousei, Loder's White, Aucklandii hybridum, cinnabarinum Roylei, fragrantissima, also the Japanese variety Kämpferi, gemmiferum and yunnanense—a very interesting and uncommon collection.

Messrs. Fletcher Brothers, Ottershaw, Chertsey, are showing four triangular groups of Rhododendrons, and among the pick of varieties are Pink Pearl, Meteor, Lady Frances Crossley and Helen Schiffner.

Hardy Rhododendrons are magnificently staged by Messrs. John Waterer, Sons and Crisp, Limited, Bagshot, Surrey. The variety Alice, which by many is considered better than Pink Pearl, is shown in finer form than we ever remember having seen it. Corona, Cynthia and Francis B. Hayes are all admirably shown.

Mr. R. C. Notcutt, Woodbridge, is showing standard Brooms in great variety, the collection including *Cytisus Beanii*, *C. Dallimorei* and *Daisy Hill*: the latter makes a splendid standard. Rhododendrons and Azaleas, both in the tent and outside, are shown in many hues of colour by the same firm.

Lilacs are being shown by Mr. Charles Turner, Slough. His best varieties include *Mme. Kreuter*, *Mme. Leon Simon*, *Souvenir de L. Späth*, *Charles X.* and the lovely double white *Jeanne d'Arc*.

Messrs. W. and J. Brown, Peterborough, are showing Lilacs in pots, including the double white *Mme. Lemoine*. The group is edged with *Heliotropes Lord Roberts* and *The Speaker*.

Messrs. Barr and Sons, Covent Garden, have an interesting group of Japanese pygmy trees—fine specimens of *Cupressus obtusa*, ranging in age from twenty to one hundred and sixty years; Japanese Larches in shallow pots, and various specimens trained in quaint forms of sacred fans, storks and chickens. Miniature landscape scenes, containing rivulets, chasms and bridges, are examples of Japanese art.

Messrs. William Cutbush and Sons make a special feature of new *Hydrangeas Lillie Moullière*, *La Perle* and *Generale Vicomtesse de Vibraye*. The plants shown carried blue flowers, the plants having been treated with *Azure*. Japanese *Acers*, *Azaleas* and *Rhododendrons* are shown in profusion, while outside may be seen an extensive collection of Cutbush's Cut-bushes—examples of toparian art.

Messrs. W. Paul and Son are showing *Rhododendrons*, *Ceanothuses* and *Clematises*, the latter in both single and double varieties. A number of Brooms or *Cytisuses* and the fragrant *Crab*, *Pyrus angustifolia flore pleno*, together with Lilacs, make up a very pleasing group. *Wistarias*, *Ivies*, *Honeysuckles* and ornamental Vines are all to be seen in this comprehensive collection.

Mr. John Klinkert, Richmond, S.W., shows clipped Boxes in many weird forms. As examples of toparian art the trees were remarkably well grown and trained.

Clipped Yews, Boxes and standard Bay trees were shown in great numbers by Messrs. Piper, Barnes, Surrey.

A circular group of *Clematises* is shown by Messrs. George Jackman and Son, Woking Nurseries, Surrey. Among the varieties will be seen *Duchess of Edinburgh* (double white), *Empress of India*, *Lasurstern* and *Nelly Moser*. *Azaleas*, *Lilacs* and Brooms are also shown by this firm.

Mr. L. R. Russell, Richmond, is also showing *Clematises*, and outside he is showing *Azaleas* and *Ivies* mingled with *Ceanothuses* and Japanese *Maples* in wonderful variety.

Messrs. R. and G. Cuthbert, Southgate, have succeeded in creating a perfect blaze of scarlet, orange and yellow with their *Ghent Azaleas*. Many of the varieties are the result of crossing *A. mollis* and *A. sinensis*. The bright golden yellow *Anthony Koster* is a feature of this group.

A collection of old *Wistaria* plants grown in tubs or bowls. These plants arranged with Japanese pygmy trees in *Cupressus* and *Acers* make a very inviting *Wistaria* garden.

Messrs. Paul and Son, Cheshunt, Herts, are showing pot *Rhododendrons* uniform in size and beautifully flowered. *Pink Pearl* is, of course, a feature, and other good varieties are *White Pearl*, *Jupiter* and *Helen Paul*.

Messrs. Cheal and Sons, Limited, Crawley, Sussex, have a well-designed formal garden with

pillars and arches clothed with rambler *Roses*. The beds on either side are planted with *Viburnums*, *Azaleas*, *Rhododendrons*, *Lilacs* and *Ceanothuses*, with pleasing effect. At one end is a formal recess banked up with rockwork and retaining walls, suitably planted.

The Donard Nursery Company, Newcastle, County Down, are showing many choice and rare shrubs, including *Leptospermum scoparium* and the varieties *Nichollii*, *Chapmanii* and *Boscawenii*, *Tricuspidaria lanceolata* and *T. dependens*, *Pittosporum* in variety, *Enkianthus cernuus* and *Deutzia gracilis roseus*. Altogether a most interesting collection of rare shrubs.

Japanese *Maples* in endless variety are shown by Messrs. W. Fromow and Sons, Chiswick, W. The deep bronze-tinted foliage of *palmatum purpureum*, *p. atropurpureum* and *p. Crispii* associate with telling effect among the lighter tones of *Acer japonicum aureum*, *A. corallinum* and *A. reticulatum*.

FRUIT AND VEGETABLES.

From the Hon. John Ward, Hungerford, may be seen a first-rate collection of scarlet, green and white fleshed Melons. Superlative (scarlet) and *Emerald Gem* (green) are perhaps the pick of a very fine lot.

Messrs. Sutton and Sons, Reading, quite excel themselves in quality and arrangement of their superb collection of vegetables. Among the produce will be observed: *Cucumbers Unique*, *Lord Roberts*, *Satisfaction* and *Pride of the Market*; *Peas Hundred Fold* and *Duke of Albany*; *Tomatoes Invicta*, *Early Market* and *Magnum Bonum*; *Potatoes Ringleader* and *May Queen*; and many other kinds.

The Hon. Vicary Gibbs, Aldenham House, Elstree, sends a collection of vegetables of the high standard of excellence that we have learnt to associate with the name of Mr. Edwin Beckett, the capable head-gardener. The *Peas* are exceptionally fine, particularly *Duke of Albany* and *Quite Content*. *Asparagus*, *Cucumbers*, *Cauliflowers* and *Tomatoes* are all shown in the height of perfection.

A dainty collection of early vegetables is staged by Messrs. H. Cannell and Sons, Eynsford, Kent. *Tomatoes*, *Peas*, *Cucumbers*, *Cabbages* and *Potatoes* are all well shown.

Messrs. Carter and Co., Raynes Park, are to be complimented on the arrangement and the quality of their group of vegetables. *Peas*, *Cucumbers*, *Radishes*, *Beetroot*, *Celery*, *Turnips* and *Tomatoes* are to be seen in great variety, and the arrangement is all that can be desired.

The collection of well-kept *Apples* staged by Messrs. G. Bunyard and Co., Maidstone, is deserving of great praise. The collection includes *Lane's Prince Albert*, *Lord Derby*, *Bowhill Pippin*, *Newton Wonder*, *Clark's Seedling*, *Newtown Pippin*, *Annie Elizabeth*, *Beauty of Kent*, *Sandringham* and many others, also *Pear Uvedale's St. Germain*.

Early vegetables are nicely shown by the Thatcham Fruit and Flower Farm, Newbury. *Carrots Demi-longue de Hallé* and *Early Horn*, and *Peas Pioneer* and *World's Record* are foremost among the features of this collection.

Messrs. Laxton Brothers, Bedford, are showing a most tempting exhibit of *Strawberries*, *Gooseberries* and *Currants*. Fruiting plants of all kinds are shown, the exhibit containing numerous baskets of *Strawberries*, such as *King George*,

The *Earl and International*, in the foreground. The *Strawberries* are of superb quality and beautifully finished.

The King's Acre Nurseries, Limited, Liverpool, are showing fruit trees in pots, all nicely cropped with fruit of the highest excellence. *Nectarine Cardinal* is especially fine, and the same may be said of *Peach Duke of York*, *Plum Rivers Early*, *Apple Lady Sudeley* and *Figs* in variety.

SUNDRIES.

This important section of horticulture has now become a recognised feature of the exhibition, and on no previous occasion has so large and varied a display of garden requisites been seen to better advantage than at the present show. The whole of a large tent, in addition to many stands in the open, combine to provide the "hundred and one" necessary adjuncts to a perfect garden.

INSIDE THE LARGE TENT.

Messrs. Abbott Brothers, Southall, stage their well-known *Osterley table tray*, *cake stand* and *honey spoon* as special features.

Messrs. Barr and Sons, King Street, Covent Garden, W.C., present a most interesting display, showing garden tools, including their most useful bulb planter, cutlery and other garden requisites.

Nesting-boxes and hanging pots for alpine plants to use on fences and special manures are among the features shown by Messrs. Barrie and Brown, King William Street, E.C.

Messrs. Joseph Bentley, Limited, Barrow-on-Humber, are showing their famous horticultural specialities, which distinctly proves the great advance in horticultural chemistry during recent years.

Paper pots, seed pockets, filling machines and general sundries of a wide and varied character are staged by Messrs. Blake and Mackenzie, Limited, Islington, Liverpool.

A novel stand is arranged by the Boundary Chemical Company, 27, Cranmer Street, Liverpool, showing the use of their "Simplicitas" patent cord netting for training Sweet Peas growing in boxes. Lawn sand, weed killer and spraying syringes are also being shown on the same stand.

A thoroughly interesting and instructive display is that staged by Messrs. James Carter and Co., Raynes Park, S.W., showing the method by which all seeds sold by this firm are scientifically tested.

Messrs. Joseph Cheal and Sons, Crawley, Sussex, have a wide display of landscape plans and photographs relating to their work in connection with the garden.

Messrs. William Cooper and Nephews, Berkhamsted, have a most interesting stand of insecticides, weed-killers, spraying pumps, &c., on view.

Garden books and papers are prominently shown by *Country Life*, Limited, in the Lime Avenue in a prominent and picturesque manner.

The Economic Fencing Company, Billiter House, Billiter Street, E.C., have good examples of their well-known fencing erected for inspection and to demonstrate the simple method of construction.

The Four Oaks Spraying Machine Company, Sutton Coldfield, Birmingham, stage in their usual form a thoroughly representative display of garden syringes and sprayers of all sizes and suitable for all gardens, from the smallest to the largest. Modern scientific improvements, together with the best workmanship and material, are synonymous with the goods on view.

(Continued on page xvi.)

TWO MOSSY SAXIFRAGES.

SAXIFRAGA DECIPIENS AND S. PEDEMONTANA.

FOR the shady parts of the rock garden there are no more useful plants than the Mossy Saxifrages. During the whole of the year they provide beautiful green carpets of foliage that are very attractive at all times. In the late spring and early summer the white or rosy pink flowers are produced in great profusion, covering the whole cushion with sheets of bloom.

The cultivation of the Mossy Saxifrages is not difficult. They all like a light, rich, but well-drained soil that never gets dry. The best aspect for them is one facing north-west or north-east; but they will flourish equally well in full sunshine, providing they are supplied with plenty of moisture. They are among the easiest of plants to propagate, the best method being division of the roots soon after the plants have flowered. The divided pieces should be planted in a made-up bed on a shady border, and kept supplied with water till they are well rooted. Of the two kinds here illustrated, *S. decipiens* is one of three species that are most difficult to distinguish one from the other. Between both *S. caespitosa*, *S. sponhemica* and *S. decipiens* are intermediate forms that connect the three together in an unbroken chain. They all hybridise so freely in gardens that one cannot rely on seeds as a means of propagation if a certain form is desired. *S. decipiens* is a Northern European plant of rather more robust habit than the other two, with taller stems and larger white flowers. There are many named varieties of it grown in gardens, including *groenlandica*, *quinquefida*, *Steinmannii* and *Sternbergii*, not to mention all the red-flowered kinds like *S. decipiens grandiflora* and *S. d. sanguinea*. *S. pedemontana*, also known as *cervicornis*, is more distinct. It produces a dense carpet of rosettes, composed of mostly three-lobed leaves that are rather thick and strongly nerved. The flowers are borne in April and May on stems about six inches high. It receives its name from the fact that it was first introduced from the Alps of the Piedmont, but it is also found in the Pyrenees as well as on the Swiss Alps.

SAXIFRAGA DECIPIENS AND S. PEDEMONTANA FLOWERING TOGETHER IN THE ROCK GARDEN.

THE CROWN CAMPION.

In the Crown Champion, *Lychnis* or *Agrostemma coronaria*, we have an old-fashioned flower which has yet an abiding-place in many good gardens, and which has survived the rout of the hardy plants which took place when the bedding system was in full sway in most gardens. It is a general favourite still, although it has now hosts of worthy rivals in the field for the favour of the cultivator of hardy plants. It is fairly well known to the many, with its greyish silvery-looking leaves and stems and its

heads of pink, white, or crimson flowers on stems about two feet high, or sometimes rather less. It is not an absolutely perennial plant, as the writer has found not only in his own, but in other gardens; but there is little fear of losing it, as it seeds freely, and from self-sown seeds a numerous progeny will spring to maintain the family line. To make a beginning, a few seeds should be sown under glass in spring, or in April, May, or June in a shallow drill in the open garden, the seedlings being pricked off when large enough to handle. It is needless to give lengthy directions as to raising *L. coronaria* from seeds, however, as it is as easily done as any hardy annual or perennial can be. It may also be increased by side shoots taken

off in summer. Some of these will be rooted, but if they have not emitted roots they can be readily struck under a handlight or a bell-glass.

A dry soil answers best for this Crown Champion. I have seen capital plants growing in mere gravel, although they were not so tall as those in the border. The type plant seems to have red flowers, although some think that the one called bicolor, which has white flowers with a red centre, is in reality the typical one. Then there are a large-flowered variety called *grandiflora*, a pretty pure white one called *alba*, a brilliant crimson one named *atrosanguinea* (the best of all), besides the doubles, which the writer has not seen now for many years. *Dumfries*.

S. ARNOTT.

HARDY CYPRIPEDIUMS.

(LADY'S SLIPPER ORCHIDS.)

THE hardy *Cypripediums* are all attractive plants, and worthy of more extensive cultivation. Most of them can be grown with a little care and attention. Fond of somewhat shady and sheltered positions, they are, with few exceptions, found growing in open woods, with the spreading roots running among the decayed leaves that have been accumulating for many years. They may be grown in the rock garden in low-lying spots that are thoroughly well drained and also have the necessary shade.

They are not deep-rooting plants, so it will only be necessary to take out the original soil, if unsuitable, to the depth of about a foot. If the soil is heavy, plenty of drainage in the way of broken bricks will be needed; but if the soil is sandy, little will be required. For the majority of the different species a suitable soil may consist of equal parts of rough peat and well-decayed leaf-soil, some loam and sand, while old sphagnum moss incorporated with the mixture will be found helpful in retaining moisture. Charcoal is often used to keep the soil sweet. Most kinds will grow in this compost, some exceptions being our native *C. Calceolus* and the Siberian *C. macranthum*, which prefer a loamy soil with the addition of lime. For these, lime must be added in the form of broken limestone or mortar rubble.

The best time to plant *Cypripediums* is in the autumn, as soon as the plants can be procured. These should never be allowed to get dry, as the fleshy roots soon shrivel up if the plants are kept out of the ground too long. With the introduction during the last few years of some new species from China, there are now seventeen hardy *Cypripediums* in cultivation.

***Cypripedium acaule* (*C. humile*)** is a North American species with a pair of broad, hairy leaves, from between which it pushes up a flower-stem over six inches long, surmounted by a green bract and single flower. The sepals are whitish,

while the large pouch is of a bright rose colour veined with crimson. It is distinct from all others in the pouch being split right down the face, giving it a two-lobed appearance.

C. arietinum is a pretty little plant, less easy to grow than most other kinds. The sepals are greenish white, while the lip is white and suffused with rose on the front. It is found in somewhat damp woods in North America.

C. Calceolus, a native of this country, is excellent for naturalising in woods, especially where the soil is of a heavy and calcareous nature. When established, it makes large tufts of many stems, each producing two or three flowers, the sepal of which are deep brown, while the pouch is yellow.

This plant is found in many parts of Europe and Siberia.

C. californicum is an interesting species with tawny yellow sepals and a blush white pouch obscurely spotted with brown.

C. candidum is also very charming, with greenish brown sepals and a yellow lip.

C. fasciculatum bears several flowers on each stem, which often reaches a height of a foot. The sepals are greenish, as is also the lip, which has a purple brown margin. The above three species are less easy to keep than most of the others, and are all North American plants.

C. debile is an interesting little plant from Japan, with a pair of leaves like our native Tway-blade (*Listera ovata*), and a slender, drooping stem bearing a small single flower. The sepals are greenish, while the white pouch is spotted with brown.

C. guttatum is a rare Siberian plant, and is one of the prettiest as well as one of the most difficult to establish. It prefers soil of a light, open description, with plenty of moisture when growing, but rather dry when at rest. The flowers are of fair size, with white sepals and pouch, the latter being spotted and blotched with crimson-purple.

C. japonicum is remarkable for its pair of broad and distinctly ribbed leaves, from which

one or two flowers are produced singly on short stalks. They are large and handsome, striated and blotched with green, white, and rose purple. This plant grows freely in shade, but frequently strong crowns fail to flower.

C. luteum comes from North-Western Hupeh in China, where it was collected by Mr. E. H. Wilson, who also met with it in greater quantities on the borders of China and Tibet. It is an erect-growing plant, with solitary flowers, the sepals and petals being clear yellow, while the yellow pouch usually has a few spots of orange brown on its face. The stems are stout and leafy, and covered with a short, brownish pubescence.

C. macranthum.—This Siberian species is one of the most handsome members of the family, growing about a foot high and bearing large, almost uniform, rose purple flowers. It is partial

A DAINY LADY'S SLIPPER ORCHID: *C. MONTANUM*. THE TWISTED SEPALS ARE BROWN AND THE POUCH WHITE.

AN INTERESTING HYBRID: *CYPRIPEDIUM VENTRICOSUM* (*C. MACRANTHUM* × *C. CALCEOLUS*).

to a more loamy soil than most of the others, approaching in this respect more nearly *C. Calceolus*, with which it is often found growing in its native habitats. These two intercross and produce an intermediate plant known as *C. ventricosum*, which differs from *macranthum* in its longer, narrower sepals, narrower pouch and paler colour. *C. Thunbergii* is the Japanese form of this plant, with paler-coloured flowers.

C. montanum is a beautiful and distinct little species from North-Western America, with three or four flowers on each stem. The sepals are brownish

purple, while the pouch is white and striped with red inside. (Syn., *C. occidentale*.)

C. pubescens (*C. hirsutum*).—A handsome, free-growing species from North America. In a cool, shady spot it will thrive and produce stems up to 2 feet high, bearing large yellow flowers. The twisted sepals are pale yellow and spotted with brown.

C. parviflorum is a closely allied species of *C. pubescens*, with smaller yellow flowers, spotted and suffused with brown. It is also a native of North America.

C. Reginæ (*C. spectabile*).—One of the finest hardy Orchids and the easiest to grow. It will thrive in a shady border and form large tufts, with many of the stems over two feet high, bearing two or three flowers on each. In colour they are white, with the greater portion of the lip suffused with rich rose. In sheltered portions of the rock garden groups of it are very attractive, the necessary conditions being thorough drainage, rich soil and plenty of moisture. It comes from North America.

C. tibeticum.—A handsome species from Western China, and another introduction of Messrs. Veitch and Sons through their collector, Mr. E. H. Wilson. In habit it resembles *C. macranthum*, but its flowers are larger, with the sepals tessellated dark purple and a chocolate-coloured pouch. So far it has not proved very amenable to cultivation.

W. I.

GARDENING FOR BEGINNERS.

MUSHROOM CULTURE ON OLD HOT-BEDS.

IN the majority of small gardens the Mushroom is rarely cultivated, there being a prevalent idea that it cannot be grown without special beds and structures. Certainly, if one requires this delicious vegetable all the year round, a Mushroom-house becomes a necessity. However, there must be numerous gardens where there are one or two old hot-beds lying idle all through the summer, and it is in these that sufficient may be grown to supply the household for several weeks. Those who utilise frames for the raising of half-hardy annuals, &c., will have them empty about the end of June, the manure which originally composed the hot-bed being left in the frames until it can be dug in during the autumn months. These old beds of manure will give quite a good crop of Mushrooms without any trouble.

As a rule, a period of six to eight weeks elapses between spawning and the appearance of Mushrooms, so that June and July are very suitable months in which to spawn the beds. The manure will have lost most of its natural heat at this time of the year, but will have retained sufficient solar warmth to start the white films or "mycelium." It is essential that the spawn should be good, otherwise the Mushrooms will be few and poor in quality. For a 6-feet by 4-feet frame one brick of Mushroom spawn will suffice. This should be broken into eight or ten pieces, which should be forced into the manure at regular intervals over the bed. Do this by hand and not with a dibbler, as so many do, for this instrument leaves smooth, hollow spaces which prevent the spawn from spreading. Do not break the brick into more than ten pieces, for small pieces result in small Mushrooms.

As soon as spawning is completed, cover the bed with straw or litter of some kind and put on the lights. In about a week the spawn should have commenced to impregnate the manure. It is easy to see if all is well, for should the spawn be bad or not alive, the pieces will be considerably darker than when inserted. If, however, they appear greyish or mouldy, then the time has come for covering the bed with soil. The best soil for this purpose is undoubtedly that from an old pasture which has been stacked for about a year. It is Nature's compost, and the Mushrooms will revel in it. When applying, it should be moderately moist, the layer being from 2 inches to 3 inches thick. Beat it down solid with the back of a spade; it cannot be made too hard, as the Mushrooms will come through, no matter how hard the soil may be. The writer has seen the uncultivated Mushroom make its appearance through a hard-rolled carriage drive. Having beaten down the earth, again replace the litter, or, if this is not obtainable, the lights may be placed on the frame and the glass covered with sacking. Every endeavour should be made to keep an even temperature of 60°, which may be accomplished by varying the thickness of the covering material. The bed should be kept uniformly moist, for if allowed to become dry, the bed will almost certainly fail to produce. The degree of moisture may be ascertained by keeping two sticks thrust in the top and bottom of the bed, which should be withdrawn from time to time and examined. If found to be too dry, the bed should be moistened with a

syringe, using water of the same temperature as the bed. If litter is used, this must be removed before spraying, and returned as soon as the operation is over, putting on the lights to keep the temperature normal.

If no Mushrooms appear in eight weeks, do not assume that the bed is a failure, for it may happen that they will appear in another week or two. When they make their appearance, do not remove the covering material more than can be helped, otherwise the Mushrooms are apt to become brown on the top. When gathering, pull out the stalk, which would otherwise decay and stop the production at that part of the bed.

South Heath, Great Missenden. THROXENBY.

HOW TO GROW CANTERBURY BELLS.

For making a brilliant display of colour in early summer and midsummer few flowers can rival these

see that the young plants do not suffer from the want of water, and keep them free from weeds. If it can possibly be managed, transplant to their flowering quarters early in the autumn, as by so doing they become established before the winter sets in, and start straight away without a check when the milder weather comes round. Most amateurs have a shady border which it is always a difficulty to fill, and if any readers are in this predicament I would advise them to give these plants a trial.

Troon, Ayrshire.

G. B. W.

SOME SALIENT POINTS IN BEDDING OUT PLANTS.

THE work of clearing away spring-flowering subjects to make room for the summer-flowering ones is being attended to now, and much thought will be given to the arrangement of the new occupants of the beds. It is well to remember that the soil in the beds is poorer now than it was last autumn, and that

MUSHROOMS GROWING IN AN OLD HOT-BED THAT HAD PREVIOUSLY BEEN USED FOR BEDDING PLANTS.

old favourites, which have for so many years adorned our gardens. Plants raised from seeds last year will now be throwing up their flower-spikes, and if they are in a position at all exposed to strong winds, a neat stake should be attached to each, so that, should a storm come, one may rest assured that no damage can be done. A thorough soaking of liquid manure or a top-dressing of some approved fertiliser given at short intervals until the colour shows in the buds will be of immense benefit to the plants at this season of their growth.

Sowing Seed.—But while the grower of these plants is eagerly awaiting the result of his work during the last twelve months, he must not rest on his laurels if he wants another display next year, as the present is the most opportune time to sow seed. By sowing early, strong tufts are produced by the autumn, and only well-grown specimens make a good display the following season. Sow the seed thinly in drills far enough apart to allow the hoe to pass between, and when germination has taken place, thin out to about six inches apart. If the summer is very dry,

some fresh soil would be an advantage. In order that the soil may be kept at a certain level, some of it should be removed before the new soil is put in; then the latter and some well-rotted manure should be thoroughly mixed with the old loam. In the case of clayey loams, add some leaf-soil and a small quantity of peat for Begonias, and where the soil is fairly rich, be more sparing of the manure if Zonal Pelargoniums, Nasturtiums or Petunias are to occupy the beds. With regard to the form of the bed where sandy soils obtain, I have seen many formed with high centres, resulting in a pitch of nearly 30°. Very little water ever penetrated the dusty surface, and the plants put out never fully occupied the space they were intended to fill. In instances of this kind a flat surface is much more satisfactory.

In hot places, Zonal Pelargoniums, Petunias and Nasturtiums will succeed better than in damp, shady ones; while in the latter, tuberous Begonias, Fuchsias, Pansies, Violas and Calceolarias will thrive. It is advisable to pick off fully developed flowers at planting-time. SHAMROCK.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Early Muscat Vines.—If these were started early, the Grapes will have passed the stoning stage, and should be induced to finish ripening to as high a degree as possible. When colouring commences a constant movement of moderately dry air ought to be maintained, and the night temperature never allowed to fall below 70°, rising to 80° or 85° by day with sun-heat.

Thinning Late Grapes.—In all cases this work should be taken in hand as soon as the berries are sufficiently advanced, for if once delayed the work becomes increasingly difficult day by day, and many of the berries are injured in consequence. Avoid touching the bunches with the hand, and keep the scissors perfectly clean. The largest and best-placed berries should be left in such a manner that the full circumference of the bunches may be retained. Promote a moist atmosphere and give air with great caution.

Late-Planted Vines.—All lateral shoots may be stopped at the first joint, and keep the leading shoot from coming in contact with the glass. Shut up the house early in the afternoon in order to make the most of the sun-heat, and never allow the Vines to suffer from want of water at the roots.

Plants Under Glass.

Primula sinensis.—If seeds were sown in April, the plants will now require potting into small, clean pots. The soil may consist of rich loam and leaf-soil in equal parts, with sufficient sharp sand to keep it sweet and porous. Place them near the glass in a close pit, and syringe with clear soft water twice daily. Further sowings may be made now in finely sifted soil.

Cinerarias.—Young seedlings may be potted as soon as a second rough leaf has been made. Place them in a close, cool pit and shade from strong sun. When well rooted, ventilation should be freely given, and they must never be permitted to suffer from want of water at the roots. For successional plants sow again and grow in a clean, well-ventilated pit.

Cannas.—These plants appear to advantage in the conservatory during the summer, where they associate well with other subjects. They require a liberal supply of moisture at the roots, and will benefit by an occasional dusting of artificial manure. Plants intended for late flowering should be potted up into larger-sized pots. Rich loam and leaf-soil will suit them well.

Hard-Wooded Greenhouse Plants.—The latest batch of Azaleas will be in flower now, and will require careful attention to watering. As soon as the flowering period is over, the plants should be removed to an intermediate house and started into growth. Remove all seed-pods, and when growth commences any potting which is necessary should be done before the young growths are too far advanced.

The Flower Garden.

Bulbs.—There should be no delay in planting any bulbs which have been forced. If planted in the pleasure grounds while the foliage is green, they will retain their foliage much longer, and better results may be expected than if allowed to wither in the pots before being put out.

Salvia Pride of Zurich.—These plants should be gradually hardened and prepared for planting in the open. If pot-bound, they must be carefully watered, so that they may not become stunted before the time arrives when they may be planted out with safety. Weak liquid manure may be given at alternate waterings until they are put out.

Preparation for Summer Bedding.—As soon as the early flowering bulbs are over, the ground should be prepared for other subjects. Let the soil be thoroughly broken up, and, if necessary, a quantity of old Mushroom-bed manure or that from a spent hot-bed should be mixed with it. Beds in which Begonias are to be planted should receive special preparation in the way of good leaf-soil or some light, rich material, and may also receive a sprinkling of fine bone-meal. When all is ready,

the hardier plants, such as Geraniums, should be planted first, leaving Heliotropes, Begonias, Cannas, Iresines and other tender subjects till the last.

Dahlias.—Spring-struck plants may still be kept under slight protection, but old plants which have been forwarded in cold frames may have the lights removed, only to be replaced in case of frost. Planting may be delayed until the first week in June, especially in low-lying districts where late frosts are frequent.

The Kitchen Garden.

Broad Beans.—Another sowing of these may be made now, and, if necessary, a fortnight later. Broad Windsor is the best variety for this purpose, and will do much better if sown in trenches into which a quantity of decayed manure has been dug. Early sown Beans may have their tops removed immediately after sufficient flowers are open, and should black aphids appear, the plants ought to be syringed with a mixture of soft soap and water.

French Beans.—Plants which are pushing through the ground will require protection from frost or cold winds, but this crop will repay the cultivator for any extra trouble. Fortnightly sowings may be made from now onwards, in order to keep up a supply of tender young pods. The Belfast is one of the best for this purpose, and if picked young may be cooked and served uncut.

Potatoes.—The soil between the rows of early Potatoes should be deeply stirred previous to earthing up the plants. This will destroy numerous small weeds, as well as prepare the soil for the young tubers. In earthing up Potatoes the soil should not be drawn up to a sharp ridge, but left in such a way as to permit the rain-water to reach the roots.

Spinach.—Make frequent sowings from now onwards, choosing a cool north border for the purpose. Make a small sowing of New Zealand Spinach in a warm position. This may prove a valuable substitute for ordinary Spinach if hot weather sets in.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Broad Beans.—Where these were sown towards the end of January they will now be in a forward state, and if it is desired to have an early supply, the points should be pinched out as soon as there is a good show of blossom. Sometimes this is necessary where the crop has been attacked by fly, as it seems to be the only means of getting rid of it. Should the weather be excessively dry, the plants ought to have a good soaking of water, otherwise, if allowed to become dry at the roots, the blooms are sure to fall off.

Turnips.—Should the fly make its appearance on the young plants, no time must be lost in giving them a dusting of soot or lime. I have also found dusting with fine ashes that have been kept dry most effectual. For obvious reasons this dusting should be done in the early morning, and done thoroughly. Sometimes, however, all of these fail to save the crop, and there will be nothing for it but to make another sowing in somewhat richer soil.

Runner Beans.—As these Beans are less hardy than the dwarf varieties, it will not be wise to sow much before this date; indeed, if left until the beginning of June there will still be time to secure a crop in an average season. They may be sown in long single or double rows to screen the vegetable quarters, which at certain seasons of the year are rather unsightly. In any case a well-grown row gives a very pleasing effect when in bloom. When the young plants are a few inches high, they will require to be trained to the poles or stakes, although I believe many people top them once or twice during the season and do away with sticks. This practice is not to be recommended, more particularly in cold districts, as they take much longer to yield.

Watering Newly Planted Crops.—In dry weather these will require to be watered frequently.

This applies equally to seedlings as well as to others of larger growth. This watering is very beneficial in hastening the fresh rooting and setting the plants into growth from the beginning.

The Flower Garden.

Violets.—Young plants that were put out towards the end of last month will require to be carefully attended to at the present time, especially if the weather is hot and dry. Where there is difficulty in keeping them supplied with water, they may be shaded from the direct rays of the sun by placing some ordinary Pea sticks among the plants until they are fairly started into growth. By all means syringe them over on the evenings of fine days.

Polyanthuses.—Seed may be sown now out of doors, or, where only a few plants are required, seed may be sown in a box and placed in a cold frame. When the seedlings are large enough to handle, prick them out into a spot which is partially shaded, and work in a good quantity of leaf-mould to promote a quick growth. Established plants will have passed out of flower, and if it is desired to increase the stock, they may be split up and planted in a position as recommended for seedlings.

Sowing Perennials.—As a rule these plants are not sown early enough, more especially in late districts. Where there is a difficulty in getting plants sufficiently established by the autumn, I would recommend sowing not much later than the present date. Very often they are sown in boxes and pricked out, and finally transplanted into the open border. No doubt there is a good deal to be said for this system; still, where it is at all possible, I think we get better results by sowing in the open. I find we get much stronger and hardier plants, which are therefore better able to pull through the winter.

Rock Garden.—The majority of the plants will now be at their best, and as they pass out of flower they should be gone over from time to time, cutting off faded flowers and keeping down weeds. Make a note of those plants that are required for seed and put a label to them to that effect, otherwise they may be inadvertently cut off in the general clear up. *Primula rosea* grown beside a stream has been especially fine this season, and where it is intended to increase the stock, the plants should be divided and replanted with care, as they resent any careless handling.

The Hardy Fruit Garden.

Raspberries.—As the young growths advance, keep them well thinned out, only retaining the most likely shoots to produce next season's crop. We usually allow far too many canes to remain, with the result that they grow into a perfect tangle, and even the best of them are indifferently ripened. If the plants were not mulched with manure, as previously advised, no time should be lost in seeing to this very necessary work.

Strawberries.—These will now be in flower, and more than likely a very abundant crop of weeds will be making their appearance. These should be removed at once, as if left they seriously interfere with the swelling of the fruit, besides the chances of their running to seed. Have all the protecting material put down at once.

Fruits Under Glass.

Orchard-House.—As all the fruit will now be swelling, it will be necessary to maintain a buoyant atmosphere. On fine days use the syringe freely to keep aphids in check, and it will still be necessary to exercise care in ventilating. Keep the young growths pinched rather closely, as if this is done systematically there need be no fear of the fruit receiving a check from this pinching.

Peaches and Nectarines.—Trees that are approaching the stoning stage should be kept somewhat cooler; indeed, they must not be excited in any way. When, however, they commence the second swelling, they should be assisted with frequent applications of liquid manure. The crop must be regulated according to the state of the trees, and the temperature should be allowed to rise considerably by closing the house early in the afternoon. On the approach of the ripening stage they must have a constant circulation of air.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

ALL the plants, except, perhaps, a few of the late-struck ones, intended for flowering on single stems in small pots will now be growing in open quarters. The special ones referred to will require the protection of a cold frame with the lights off for a week or so longer.

Close Spacing of Plants.—When young plants are first removed to open quarters, it is advisable to stand them rather close together for a week or ten days. If, however, they remain so for a longer period, many lower leaves will suffer. Exclusion from full light sadly weakens them, and, although they do not fall off at once, they do so prematurely later on in the season. Place the plants in rows at least a foot apart until they are finally repotted, and then, after that operation, the large pots may be placed close together for a week or so before they are arranged in rows several feet apart for the summer months.

Feeding and Repotting must be done every week where a cultivator has to keep up the general good health of a large collection of plants. I would not hesitate to shift a plant which badly needed more rooting space in a 4½-inch pot to a 6-inch one in the middle of May, and so defer the final potting of that plant by a fortnight in consequence, than let it remain in the smaller pot and then transfer it to the flowering pot a fortnight earlier than is reasonable, or else let it remain the extra time in the smaller pot and deteriorate to a certain extent. This occasional shifting on of young plants by degrees tends very materially to maintain the whole collection in a high state of health. There are always many plants in a collection at this season that are benefited by occasional doses of liquid manure, and some with very hard stems and toughening leaves will be benefited if given a dose of nitrate of soda at the rate of a teaspoonful to a gallon of water. Such plants must possess a fair number of roots. When this is applied, the soil must be still in a moist state from a previous watering with clear water.

Poor Loam for Final Pottings.—The compost acts as a storehouse for food and a home for the roots of the plants. A vast amount of nourishment can be given through the medium of the poorest soils, but where possible a rich loam should form the great bulk of the compost for the final potting. All cultivators, however, cannot procure such good loam, and must be content with that of a poor nature. The poor loam, however, can be improved if it is procured several weeks prior to the date of using it. First chop it into medium-sized pieces with a spade, and then reduce it by hand pulling. Spread it out in an open shed or in a shady place outside, and pour some rather strong liquid manure on it—enough to saturate the whole mass through. Then throw up the loam to form a conical-shaped heap and cover it with boards or mats until the time comes for the final potting. The other ingredients may with advantage be added to it ten days before. This is a good plan to adopt with composts, both rich and poor. The mistake is often made of chopping the turf into small pieces; but experienced growers know the advantage of pulling the loam to pieces by hand.

Avon.

THE TULIP TRIALS AT WISLEY.

THE second and last meeting of the joint Tulip Nomenclature Committee was held at Wisley on May 6 and 7, when the Cottage and Darwin varieties were all carefully gone over and the names put right or noted as correct.

An accurate colour and base description of each variety is being prepared, and after next season, when the trials will be repeated, a list will be issued under the joint auspices of the Royal Horticultural Society of England and the Bulb Growers' Association of Holland. In this there will be a description of all the Cottage and Darwin varieties, with illustrations of typical bases and a list of synonyms. The committee is constituted as under: Dutch members—Mr. E. H. Krelage, president of the Dutch Bulb Growers' Association; Mr. J. Roes, chairman of the Tulip committee of the Dutch Bulb Growers' Association; Mr. Jan de Graaff, a member of the Council of the Dutch Bulb Growers'

wanted, and should do much to instruct the Tulip-loving public as to how to recognise the various types of breeder, Cottage, Darwin, Parrot, &c.

The Tulips at Wisley were in excellent condition, and it was evident that great pains had been taken in their culture, or after the trying time of drought, and then of wind and rain, which they had gone through, it would have been otherwise. Readers should make a mental note of the repetition of these trials next year with the idea of paying them a visit. It is anticipated that additional lots will be sent for planting. As there were about four thousand planted last autumn, which will nearly all be replanted next autumn, as well as any fresh ones sent in, there should be a great display, which it will be worth while anyone seeing and studying.

MAY-FLOWERING TULIPS.

(DARWINS.)

NICOLAS VAN KAMPEN AND SON were celebrated florists who flourished in Haarlem in the eighteenth century. So wide was their trade that

A VIEW IN THE TULIP TRIAL GROUNDS AT WISLEY.

Association and a member of the Royal Horticultural Society's Daffodil and Tulip committee; and Mr. Thomas Hoog, a member of the firm of G. C. van Tubergen of Haarlem, famous for the collection of Tulip species. British members—Mr. E. A. Bowles, chairman of the Royal Horticultural Society's Daffodil and Tulip committee; Mr. P. R. Barr, a member of the Royal Horticultural Society's Daffodil and Tulip committee and of the Council of the Royal National Tulip Society; Mr. G. W. Leak, a member of the Royal Horticultural Society's Daffodil and Tulip committee; Mr. A. D. Hall, the Rev. Joseph Jacob and Mr. Walter T. Ware, members of the Royal Horticultural Society's Daffodil and Tulip committee and of the Council of the Royal National Tulip Society; and Mr. C. W. Needham, treasurer of the Royal National Tulip Society.

I might also mention that a scheme of garden classification is under consideration, and it is proposed to issue this at the same time as the descriptions and synonyms. Such a scheme had

they issued lists of bulbs in English and French, as well as in their own language. I have such a list before me now, dated 1770. It contains the names and descriptions of all the Tulips, early and late, in their extensive collection. It is hardly necessary to say that these are almost entirely striped or rectified varieties. A casual remark in the description of an early one named L'Abîme (The Abyss) tells us what their feelings about the self-coloured or breeder forms were. Here it is: "The breeder of Hecuba, perfect in every respect, but only a breeder." "But only a breeder"; there's contemptuousness for you. But so it was, and so it continued to be until very modern times indeed. I have seen many illustrations and many lists of Tulips with descriptions from the time of this list of van Kampen's up to the present day, but it is only within the last thirty or thirty-five years that the self varieties which we now call "Cottage" have appeared, and at a later date still, the "Darwins." I have often puzzled my head to know

how it was that these plain or self-coloured forms were never valued in the past. I have many views on the subject, but none quite bears the test of probability and experience. This is my latest. I have in bloom now—or I had until yesterday, May 11, when by far the worst hail-storm that I have ever had in Tulip-time visited my garden—four large beds of old Dutch breeders. As the result of a hint that these were the type of flower that the Pilgrim Fathers used to cultivate in the old land before the Mayflower sailed, my friend Heer Jan de Graaff tells me that the people of the New England States are mad about them. They are undoubtedly a little sad and dull-looking, and I am now wondering if this can be the key to such a remark as "only a breeder." Put such kinds as Vertumnus, Charles Dickens, General Ney and Le Grand Conquereur, which are some of the best of them, side by side with Petrus Hondius, Farncombe Sanders and Pride of Haarlem, and ninety-nine people out of a hundred would prefer the latter for garden decoration on account of their brighter and gayer colouring.

I find the old saying of every dog having its day is, roughly speaking, true of Tulips. Where they are not wanted for cutting and where there is no drawing-room to think of, bright pink and lavender and mauve Darwins seem to be the ones most admired at the present time. Erguste and Euterpe are always singled out, the first being a blue mauve, and the second a pink mauve and rather a larger flower and taller plant. Both are very lovely. A third variety of an even more fascinating shade is the old Cottage Darwin-looking variety Salaman, with its pure white base and silvery tone. In its general shape it very much resembles a Darwin. It is useful for a succession, as it blooms a week later than the two mentioned. In the larger and more robust-looking deep greys and dark mauves there is the same difference between the two most often seen, La Tristesse and Remembrance, as between Euterpe and Erguste. The first have a more rosy look in their young state and developing with age into more of a bicolor, as the three inner petals take on a pearly grey, which contrasts sharply with the darker purple of the exterior ones. The largest and tallest is Ronald Gunn. He looks as if he had gone to a fancy-dress ball as a billiard cue. The white tip is characteristic of youth. With age it either disappears or the grey edges of the petals develop and it is lost. This is a very handsome Tulip. Of the real darkies, such as La Tulipe Noire, Ph. de Commynes, Faust, Black Night and Zulu, none is more effective, nor has any been more admired with me, than Fra Angelico. It has a large, round, open flower, and always looks so rich and glossy. Background is everything to these dusky gentlemen. I have more than once seen bedding effects marred by this not having been thought of. There comes to my mind now a row of bright reds and yellows, and in their midst unaccountable gaps. Have there been failures? No; it is only the dark Ph. de Commynes or Leonardo da Vinci that do not show. As Fra Angelico is one of the earliest Darwins, I would suggest Faust for a second dark, or (only I fear the price is high) Ravenswing. Both are exceedingly handsome, long-shaped flowers, and contrast well with the rounder-shaped "Fra." Bright pink and cerise shades have been much noticed this season. I have only a hundred or so bulbs of the fascinating Louise de la Vallière, but no one passed it without remarking upon its beauty. I call it a warm

soft rose, with just a suspicion of a salmon shade all over it. Then there is Petrus Hondius, a large and more open bloom, not quite such a tall grower and with more carmine in its composition—exceedingly bright; in fact, one of the brightest of all Darwins. A later bloomer which somewhat takes after Farncombe Sanders in colour is Galatea. I have found it very satisfactory in every way—bright, large and tall.

The scarlet red shades seem down on their luck. A lovely richly coloured bed of the truly magnificent City of Haarlem is invariably passed by. So is Feu Brilliant, and so are Nerine, Scarlet Beauty, Laurentia and Teddy. And yet the latter's nearest companion, Maiden's Blush, a pretty rose pink with a very wide, pronounced blush edge, is usually singled out. Another of these pinky rose bordered varieties that almost everyone has passed some appreciative remark upon is La Fiancée. Tall and *embonpoint* she stood among her compeers. It seems she must be noticed even to the very end. I think I have four of the very best yellow-browns: Gondvink, the tall, large, tortoiseshell-comb coloured one; Clio, the rice baked biscuit; Golden Bronze, rich gold and brown; and Quaintness, a somewhat pale-looking brown, with the edges and the interiors of the petals of quite a yellow shade. These are among the kinds that are so popular over in America, and as I am very partial to them myself, I think it shows Brother Jonathan's good taste. The dark purples, by which I mean such varieties as Frans Hals, The Bishop, Jubilee, Viking, Moralis, Velvet King, Valentin and The Giant, seem to be, with the exception of Moralis and Valentin, redder than usual this spring. I thought the same one year before, but I am never able to decide whether it is imagination or reality, for I know how difficult it is to carry an accurate impression of colour even from day to day. Probably Valentin has been more admired than any other Tulip in my garden. The silvery-looking bluish purple of its immense flowers, borne as they are on long stems, at once catches the eye, and it keeps on doing it; it is such a wonderful luster. Out first, it is still there even when the Darwin season is far advanced. My great favourite, the deep blue purple The Bishop, attracted everyone last year whenever it was shown, and was eagerly bought up. There is nothing with quite the same rich deep blue tone among the purples, for usually they incline very much to the red side. Viking is as near to it in colour as any, but it is more of a bicolor, the exterior of the inner petals being so much paler than the outer ones that the solid self look of The Bishop is wanting. Moralis might almost be described as a very dark blue. It is so far away from the red-toned purples that it might well be put in a class by itself. A dark breeder, by name Sappho (syn. Regal Purple), is very much the same colour, and is covered with a similar bloom, just like the well-known Kirke's Plum. Everyone should try Moralis, but it must not be forgotten when assigning it a place that it is one of the darkest of the darks, and must have suitable setting if justice is to be done. The ruby reds must not be forgotten. They are not magentas (that most unfortunate colour that no one, or *hardly* anyone, likes); but they have each of them a certain amount of blue in their composition. They range from the splendid old Pride of Haarlem to the comparatively unknown Jeffries, which always brings to my mind a parcel of unset pigeons' blood rubies that I once saw in Rangoo Tara

(syn. William Goldring) is a very old favourite with me. It has a large flower of a bright ruby red shade, borne on a plant of medium and quite sufficient height. Palisa is the only other one of this colour group that I will mention. I call it one of my 1914 finds. It happened in one place to be next to Sierrad van Flora, and the two made such a capital and novel combination that I feel I may suggest it as a possibility for next season. Both will be found among the cheaper ones, which is a point in their favour. The colour of Palisa is a bright-looking, deep-toned ruby red.

Wall-papers, cloth clothes (for I dare not suggest that there is the same perplexity among the fair sex as among us men) and Tulips are all in the same category when with many spread before us it comes to making a final decision. Even now I want to erase some of what I have just written and put in other names. I do envy a man who can choose, such, let me say, as Mr. Leak of Messrs. R. H. Bath, Limited. He and I were among those who went to Wisley to judge the Tulip trials. Although there was not every Darwin in the world there, the number of those that were was legion. We both utilised our bit of breathing-time before we left by quickly going over them. When the sand was nearly run out, he surprised me by saying, "I have selected what I consider the six best." It will probably interest my readers as much as it did me to know what a man of such wide experience chose. In alphabetical order they are as follow: Alata, a warm pink with a lovely blue base; Andromaque, a fine deep cherry crimson; Anton Mauve, a tall plant after the type of Ronald Gunn and Remembrance, but the mauve in the exterior segments is much redder, while the edges have the same silvery shade; Georgia, just missed being a magenta, and as a woman who has just missed being pretty is plain, so, *vice versa*, just missed magenta means lovely—it has a white base, and is of the open shape of Bleu Aimable; Scarlet Perfection, an eye-opener; and Venus, a beautiful old rose with a white base. JOSEPH JACOB.

A LITTLE - KNOWN ROSE.

ONE of the most delightful and brilliant coloured of the Hybrid Perpetual group is, strangely, very little known; indeed, I do not know any English list that contains it. The name is François Coppée. It was raised by Ledechaux and introduced in 1895. The colour is a brilliant velvety crimson, a mixture almost of Xavier Olibo and Eugène Fürst; indeed, it somewhat resembles the latter in form, but has a more fiery scarlet towards the edges of the petals.

We shall make a great mistake if we allow some of these old Hybrid Perpetuals to be lost. Where are there any among the Hybrid Teas Roses to equal them for colour, form and fulness? Take our old favourites Victor Hugo, Louis van Houtte and Charles Lefebvre. Why, they are equal to anything among the Hybrid Teas. Of course, they do not give us much in the autumn; but still, they are superb, and we must retain them at all costs, even if they have to be relegated to the spare garden. A row or two of these gems planted in the kitchen garden would be of great usefulness to blend with the yellows and pinks of the Hybrid Teas when they are culled for the house, and if they are obtained on the Briar, they will give a fine display quite late; at least, most of the varieties will do so. DANECROFT.

THE GARDEN.

No. 2219.—VOL. LXXVIII.

MAY 30, 1914.

NOTES OF THE WEEK.

Attendance at the Chelsea Show.—We understand that the attendance at the Chelsea Show created a record. No fewer than 23,000 persons paid for admission. When we remember that there are about twenty-seven thousand Fellows' tickets available, and that these are used freely throughout each day, some idea of the total number of visitors is obtained.

An Early Harebell.—All who have a rock garden, whether large or small, should include Steven's Harebell, *Campanula Stevenii*. It is the first of the genus to greet us, and the attractive blue flowers are borne in such profusion as to almost hide the plant. There is a variety, *nana*, which differs very little from the type, except that the flowers are practically sessile among the leaves. The white variety also is very beautiful. All must be planted in well-drained soil.

A Useful Early Border Plant.—*Thalictrum aquilegifolium*, the Tufted or Feathered Columbine, is without doubt the best of the Meadow Rues. In flower it is particularly charming, and is sure to attract attention when seen in well-established groups, as the corymbose panicles of creamy purplish blossoms are very striking, and the foliage handsome and distinct. There are several well-marked varieties, all of which are worthy of cultivation. They are not particular as to soil, but should be left alone for a few years.

Pentstemons and Antirrhinums.—These are to a large extent displacing the more tender subjects in the adornment of our flower gardens, and this is not to be wondered at, seeing they give a wealth of bloom over such a long period and can be grown by the novice. No time should be lost in getting them into their flowering quarters, as everything depends on a good start. In planting, do not overcrowd in the bed, otherwise they cannot produce such handsome spikes as we associate with these plants.

Ten-Week Stocks and Asters.—These should now be ready for planting out, and in doing so it will be advisable to give them a little more attention than they often receive. We are usually very careful about attending to the little details as to the sowing of the seed, but the planting out is often done in a very haphazard way, with the result that half the beauty of these delightful annuals is lost. Should the soil be of a heavy nature, fork in some light material, such as old potting soil, and some well-rotted

manure. In planting, select a dull day, and with this little extra care it is surprising the difference one gets in the results.

Damage Caused by Lightning at Kew.—Two trees were struck by lightning during the severe thunderstorm which swept along the lower reaches of the Thames Valley on the evening of May 22. One of the trees was a large Sweet Chestnut standing near to the stables in the Arboretum, and the other a Cedar in the Cedar Avenue near to the Pagoda. In the latter instance the bark of the tree was stripped in spirals, the shattered bark and cones being distributed on the ground around the tree. Two flagstones

Growing Tomatoes in the Open.—Plants must be well hardened before they are set out, and if showing their first bunch of flowers, so much the better. The soil should be well prepared and a small quantity of decayed manure incorporated with it. If space is available on a south or west wall, there can be no better position for them.

Our Chelsea Show Number.—We wish to thank the numerous readers who have written such highly appreciative letters about our Special Chelsea Show Number. This special issue was quickly sold out, but to meet the demand we had a few extra copies printed. Anyone who failed to secure one can obtain a copy direct from this office, post free 2½d. We also thank them for their kind congratulations and the judges' award of a silver Flora medal. THE GARDEN was the only horticultural paper to receive an award from the judges.

Sun Roses for Dry, Sunny Banks.—

Few plants are more valuable for such positions than the *Helianthemums*, which are now giving their masses of flowers, from purest white to deep crimson, with almost every intermediate shade of colour imaginable, completely hiding the foliage and producing such a blaze of colour as is seldom found in any other class of plant. The warmer the position the brighter and freer they flower, and they are ideal subjects for such places, where the majority of plants would fail. They are readily raised from seed or from cuttings.

Royal Gardeners' Orphan Fund.—

At the twenty-sixth annual dinner, held recently under the presidency of Baron Bruno Schröder, the sum of £1,200 was collected in aid of this very deserving charity. This is the second highest amount that has been collected at the

A GRECIAN WOODRUFF, *ASPERULA SUBEROSA*, IN THE ROCK GARDEN. IT HAS DAINTY FLOWERS OF A PLEASING PINK SHADE.

in the pathway near to the Japanese Gate were moved from their positions by lightning, one of them being turned completely over.

A Grecian Woodruff (*Asperula suberosa*).—This beautiful little plant, with dainty pink flowers and woolly foliage, is well adapted for a dry corner in the rock garden. Like most other plants with woolly foliage, it needs protection against damp, especially during the winter. June is its month for flowering, but this year, owing to the spell of warm and dry weather, it is flowering a little before its time, and many an alpine garden is all the more interesting owing to the presence of this pretty mountain flower. It is synonymous with *Asperula Aethoa*.

annual dinner. There is reason to think, however, that further subscriptions will be needed to meet the many distressing cases that are brought before the committee. Since the election of candidates in February there are already sixteen orphans awaiting the help extended by this charity. The Fund makes an allowance to aid in the maintenance and education of the orphans until they reach the age of fourteen years, and assists them in the purchase of clothing or tools or in providing apprenticeship fees when they are commencing to earn their own livelihood. The secretary is Mr. Brian Wynne, 19, Bedford Chambers, Covent Garden, London, to whom all communications should be sent.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Protecting Gentians with Glass.—I also had very good results from covering the Gentians as recommended by Mr. R. A. Malby in *THE GARDEN* last year.—R. H. H.

Tulip Yellow Rose.—This is a very old double variety, seemingly derived from *Tulipa suaveolens*. At any rate it is sweet-scented; but its greatest charm is its colour—like splashes of yellow May butter. I used not to like it on account of its flowers being so heavy that they always bent to the ground. But that failing, like some others, is not without its compensations, and the large, sprawling lumps of yellow lying on the ground are forgiven for their exquisite colour tones, and in sunny weather they are not at all out of place in that lowly position.—R. P. BROTHERSTON.

Beautiful Seeds.—As I have been an interested reader of *THE GARDEN* for several years, I have been rather disappointed that mention is seldom

Tulips branched last year, with the exception of *Fashion*, which is known to have a leaning that way. There are no more interesting plants than these late Tulips, and if anyone is thinking of going in for them for the first time, let me suggest that they include in their lists *Isabella* and *Fashion*, for it is most fascinating to watch the extraordinary change in colour which takes place in these Tulips during the four weeks that each flower is out. Some Tulips fade early, but these two improve steadily. Another Tulip of great interest is the mahogany *Dom Pedro*, which I saw spoken well of in *Country Life* last year, and as a novelty it is well worth having.—(Dr.) R. C. LOWTHER, *Grange-over-Sands*.

School Shows.—As a result of a recent article of mine on the subject of school shows, I have had an interesting communication from the Chairman of the Grange School Board, Banffshire, who has initiated a show for the three schools under the Board somewhat on the lines of our own. The Grange Show was entirely confined to members of the *Narcissus* family. Essays and notes on the growth of the bulbs, and coloured and black-and-

note on the above subject. I do not expect my sport will prove constant, for the plant from which it sprang was gathered as a white-flowering variety, and it also flowered white last year with three or four flowers. On watching it this year it was found to have one flower of the normal blue, one quite white, excepting the green-speckled throat, and, lastly, that flower with the two shades together. I have not had the heart to disturb the plant, as we cannot congratulate ourselves that *G. acaulis* has satisfactorily established itself; but I hope to find out yet whether all these three varieties come from the same plant. Following up my note in your issue for July 26, 1913, page 376, on "*Gentiana verna* in Grass," when I reported a first success of twenty-eight flowering plants from my annual sowings, I may briefly state that this spring there were 114 such, besides innumerable small seedling plants, and having scattered 100,000 seeds (which means millions of grains) last autumn, I hope I shall live to see the lovely sight of them flowering yet.—E. HEINRICH.

Fragrance in Sweet Peas.—As one who has grown Sweet Peas for a few years, and who has chosen the varieties recommended by the National Sweet Pea Society, as well as others of my own choice, I can, with regret, bear out what your correspondent B. W. Lewis says in *THE GARDEN* of May 23, page 255, with regard to the loss of perfume in the newer Sweet Peas. But there is one Sweet Pea (which I grow for garden decoration and cutting) which stands out clear in front of all others in good points on my heavy soil. It is the strongest grower, and gives the largest bloom (excepting *King Manoel*) of a pleasing colour, four on nearly every stem, which is very long, and last, but far from least, it possesses a most delicious perfume. It is the bicolor *Mrs. Cuthbertson*.—H. P. B., *Bristol*.

Too-Much-Alike Auriculas.—In response to "Taplow's" request for a list of alpine varieties, I beg to submit the names of a few selected from my stock of seventy different named kinds. These cover a wide range of colours, and have been in commerce for several years, and should not be expensive. If so, I would suggest to your correspondent that he joined one of the societies which make a speciality of this fascinating flower, and I think he will find the members ever ready to supply him with a few surplus plants. Gold centres: *Chamoise*, *Charmer*, *Duke of York*, *Ettrick*, *General Buller*, *George Cadbury*, *J. F. Kew*, *Majestic*, *Muriel*, *Pluto*, *Unexpected* and *Violet Vanbrugh*. Light centres: *Admiration*, *Argus*, *J. T. Bennett-Poë*, *Blue Bell*, *Phyllis Douglas*, *Prince of Tyre*, *Thetis*, *Mildred Jay* and *Janet*. I wish to state that this list includes some varieties which are not quite up to the standard required for show purposes, but have been included on account of their charming colours; for instance, *Admiration*, a lovely shade of porcelain blue; and *Chamoise*, deep apricot. As alpine varieties make numerous offsets, a good stock is soon attained. If your correspondent only requires the plants for decorative purposes, he should obtain a packet of seeds from Mr. James Douglas or Messrs. Phillips and Taylor, and he would get a wonderful range of colouring; but some patience is required, as it takes two or three years to obtain good flowering plants. Some of the brightest colours come pin-eyed, a serious defect in the eye of a judge; but a place can be found for them on the rockery or slightly shaded border.—LANCASHIRE. [We are compelled to hold over until next week other interesting correspondence on this subject.—ED.]

SEEDS OF *CARALLUMA SIMONII*. THE SILKY STRANDS ATTACHED TO EACH ARE VERY BEAUTIFUL AND FORM A READY MEANS OF DISTRIBUTION.

made about Cacti. There must be many lovers of these curious plants, so I have pleasure in sending herewith a photograph that I have just had taken of the ripe seed of a succulent plant called *Caralluma Simonii*. The blooms are of a dark brownish colour and shaped like a star. The plant from which this seed was taken bloomed in 1912, and last year the pods were formed. These pods have just opened, revealing a dozen or so fine silken puffs, one of which I am sending you. Some of your readers may be interested in this picture, and I should be glad if you are able to use it.—ALFRED BENTLEY, 27, *Wards Road, Seven Kings, Essex*.

May-Flowering Tulips.—One of my late Tulip beds has proved of unusual interest this year, since a large number of the stems have carried four or three full-sized flowers. These include *Fashion* (4), *Jaune d'Œuf* (4), *Inglescombe Pink* (3), *La Merveille* (4), *Ravenswing* (2), *Globe of Fire* (3), *Fairy Queen* (2), *Calypso* (2), &c. Nearly all the *Fashion* bulbs have three strong stems, the branch taking place above the leaves. I daresay this is quite common, but none of these

white sketches of the flowers added interest and utility to the competition, and were adjuncts which may be brought in where circumstances permit. From correspondence between the masters of the schools and Mr. Pritchard, I cannot help feeling that the educational side is thrust rather too much down the children's throats. Overdone, it may have the diametrically opposite effect to that which I for one would wish these shows to have, viz., the fostering or the sowing a love of flowers for their own sake. I would not like a school show which is only the Black Currant jam for the powder. I think, too, it is better to have several sorts of flowers grown, and not only Daffodils. If it was Daffodils one year and Hyacinths the next, it would not be so bad; but give me variety.—JOSEPH JACOB.

Gentiana acaulis Sporting.—As on the occasion of the recent opening of our spring flower show at Munich I had the honour of presenting to one of the Royal Princesses a peculiar flower of *Gentiana acaulis* showing the true Bavarian colours, pure white and blue (lengthways divided), I was much interested in Mr. R. R. H. Hayes' (Keswick)

Chair Cane for Sweet Peas.—The writer of an interesting note in *THE GARDEN* recently advocated the use of chair cane for training Sweet Peas. He said it costs 6d. a pound. I can only find prices running from rs. 6d. a pound upwards.—**E. P. DEAN.**

The Double-Flowered Gorse.—Apart from the fact that when in bloom this is a really gorgeous shrub, it has also other highly meritorious features. The principal one is that it will thrive in dry, stony soils, even on hot banks where practically nothing else can be depended upon; in fact, under such conditions it is far more floriferous than in a deeper and richer soil. One especial point to bear in mind is that the double-flowered Furze or Gorse very much resents transplanting; hence it should be grown in pots till placed in its permanent quarters. Cuttings put in sandy soil in a shaded frame in August will soon root.—**H. P.**

Primula Leddy Pilrig.—The hybrid *Primula* called *Leddy Pilrig*, which obtained a first-class certificate from the Royal Caledonian Horticultural Society at their spring show on April 29, is quite a good plant, and rather pleasing with its whorls of soft rosy flowers. It was raised at *Pilrig House*, Edinburgh, by Mr. Robertson, the gardener there, and its parentage is given as *P. beesiana* and *P. bulleyana*. Some good authorities are disposed to doubt the correctness of this, but the raiser has doubtless the best knowledge of the matter, although there are suggestions of the pulverulenta "blood" in the appearance of the plant. The *Primula* has the foliage of such plants as *P. pulverulenta*, *P. bulleyana* and others, and looks as if it would prove a free grower and good bloomer. There are only a few plants in existence as yet; but, as it is likely to increase well by division, it should soon be plentiful.—**S. ARNOTT.**

Cytisus Daisy Hill.—The note which appeared on page 241 of *THE GARDEN* regarding the two beautiful Brooms (*Cytisus præcox* and *C. albus*) brought to my mind another very pretty variety which is not often seen, but one which, on account of its unique and distinctive character, deserves to be more largely planted than it is. *C. Daisy Hill* emanated from that well-known home of hardy plants at Newry, Ireland, whence it takes its name. It is quite distinct in coloration from any other Brooms of my acquaintance, being a combination of yellow, rose and violet crimson, which must be seen to be fully appreciated. In every other respect it resembles the common yellow Broom, and is equally as hardy and floriferous. Those interested in these handsome, easily grown shrubs and in search of something novel should secure a plant or two of this variety, and I feel sure they would be delighted with the charming effect made by the rather unusual combination of colours. While on this subject I would call attention to another choice *Cytisus*, which flowers during the late summer and autumn, at which period its rich golden blossoms are much appreciated. This is *C. elongatus*, a neat, erect-growing shrub of great beauty, carrying graceful sprays of bloom from 1½ feet to 2 feet long. It grows equally as freely as the other Brooms, but is more neat and compact in habit. It flowers with lavish profusion and ripens its seeds freely, thus affording a ready means of increasing the stock. Both of these shrubs last year flowered with great freedom in Mr. Brough's garden at Ochilview, Perth, standing out conspicuously among the comprehensive collection of choice shrubs grown there.—**W. L.**

Primula floribunda.—Since the advent of *Primula kewensis*, one sees very little of *Primula floribunda*, though it is, I think, so pretty and so continuous flowering that its merits ought on no account to be passed over. It is a native of the Himalayas, and has been grown in this country for fully thirty years. Grown from seeds, which is the best way of increase, it forms a rosette-like tuft of leaves, which soon produces several offsets. The flower-stems, which in good examples are numerous, reach a height of about nine inches, and bear small, bright golden yellow flowers disposed in whorls. Fresh spikes are continually pushed up, so that its season of blooming is a very lengthened one. There is a variety—*Isabellina*—in which the flowers are of a paler yellow than those of the type, but, to my mind at least, it is much less effective. Seed of *P. floribunda* ripens freely, and from this young plants should be raised, as those obtained from division are much less satisfactory. Apart from its own intrinsic merit, *P. floribunda* is of especial interest as being one of the reputed parents of *P. kewensis*, which originated as an accidental seedling.—**H. H.**

Our Native Flowers.—It is very interesting to note how much alike our native flowers are, even in widely separated districts. I was forcibly struck with this when reading in *THE GARDEN* for May 9 about the fine display of Furze and Marsh Marigolds near Bournemouth. Here, in South Ayrshire, we have had very fine shows of both the above-mentioned plants during the past fortnight, and the bright blossoms still continue to beautify the landscape. Another shrub which is very abundant in this district is the Sloe, or Blackthorn, and this has been flowering with lavish profusion this spring, great drifts of snowy blossoms being in evidence everywhere, the purity of the blossoms being thrown into bold relief by the black stems of the shrubs. I have never seen such a profusion of the woodland Windflower (*Anemone nemorosa*) as is to be found in this locality. Myriads of the lovely starry blossoms are met with everywhere, in sun or shade, just as numerous as the Daisies in field and glade. The blue Wood Hyacinth is now opening its drooping blue bells in the woods; in many places, so thickly are they crowded together that nothing else can grow. The Golden King-cup (*Caltha palustris*) is particularly robust this year, probably because it has had no lack of moisture. Sulphur Primroses and blue Forget-me-nots bestud the hedgerows and brighten the roadsides with their dainty blossoms, associated with the modest little Dog Violet (*Viola canina*). With such a wealth of beautiful gems among our native flora, why should travellers risk their lives amid the Swiss glaciers or Italian earthquakes to see flowers no prettier and scenery no grander than our own?—**W. L., South Ayrshire.**

FORTHCOMING EVENTS.

June 2.—Scottish Horticultural Association Meeting.

June 3.—Royal Horticultural Society's Exhibition.

June 4.—National Hardy Plant Society's Show at the Royal Horticultural Society's Hall. Linnean Society Meeting.

June 5.—Dundee Horticultural Association Meeting.

June 6.—Société Française d'Horticulture de Londres Meeting.

June 8.—United Horticultural Benefit and Provident Society's Committee Meeting.

"THE GARDEN" PLANNING AND PLANTING COMPETITION.

OUR competition for planning and planting the little garden has created widespread interest, and, judging by the number of letters we have received, there is a very great demand for good designs for little gardens. Full particulars of the competition were published in our issue of the 18th inst.; but for the benefit of those who may not have seen that issue we may briefly state that we are offering cash prizes of the total value of £33 12s., as well as a number of book prizes, for the best designs sent in. On page IV. of this issue we insert the coupon that must be sent with four penny stamps to cover cost and postage of the sheets on which the outline plans are printed, and on which the designs must be drawn. A number of questions have been raised relating to the competition, and, as we stated in our issue of May 18, these questions will be fully answered in our next number. Those who have not seen the rules and conditions governing this competition may secure them by applying to The Editor of *THE GARDEN*, 20, Tavistock Street, Covent Garden, London, W.C., and enclosing 1½d. in stamps to cover cost of postage.

THE JAPANESE PLUM IN AMERICA.

YOUR reference to the Japanese Plum (*Prunus triflora*) in April 18 issue, page 195, and the pessimistic report of its value as a fruit tree, lead me to say that this species has had a striking and peculiar career in America.

It came conspicuously into public notice about twenty-five years ago, at which time a large number of varieties were distributed by American nurserymen. Some of these were direct importations from Japan, others were seedlings accidentally picked up in America, while a few were artificial crosses made by gardeners here. For a time it seemed that these Japanese Plums would supersede all others in our commercial orchards, and even in the gardens of amateurs. Some ten or fifteen varieties became very popular and were planted everywhere. In some cases these did prove a commercial success, at least for the time being. They proved at least to have many valuable qualities combined with certain distinct defects. They are easily propagated, grow rapidly in the nursery, are easily transplanted to the orchard, come quickly into bearing, and some of the varieties yield enormously. They are excellent for preserving, jelly making, &c., and being of good size and attractive colour, sell fairly well in the open market. The trees are, unfortunately, short-lived and subject to the attacks of insects and diseases. Many of the varieties which at first promised well have in the long run proved worthless. So many disappointments have come from planting the different varieties that the popularity of this species has now greatly waned. In the meantime the Japanese Plum has been extensively used in hybridising. It crosses very readily with other species—much more readily than the common garden Plum (*Prunus domestica*). In the Central States, where Plums of native American species are extensively grown, these hybrids have arisen in large numbers. Several

of these hybrids, especially those between *P. triflora* and *P. hortulana*, have shown much value and are being propagated and cultivated on a considerable scale. It was also found that *P. triflora* would cross readily with *P. Simonii*, and that the offspring was usually a conspicuously fine fruit. Varieties of this cross nearly always have large fruits of solid flesh, which handle well in the market, though the quality is usually inferior. Several of these varieties were put on the market and widely distributed by the nurserymen. For a time it seemed that they would achieve a commercial career, but at present they have largely disappeared. There is hardly a more interesting chapter anywhere in the history of pomology than the story of the Japanese Plums in America. They have had a wide and varied development, all the events of which have taken place so recently that the facts are well known to nearly all horticulturists now living.

F. A. WAUGH.

Massachusetts Agricultural College.

HARDY JAPANESE PRIMULAS.

JAPAN has made an unexpectedly small contribution to the hardy Primulas which are in cultivation, and, even if we include those which are yet to be brought to our gardens, the known species and their forms are wonderfully few in number. Only eleven species are native, eight of them endemic. Counting microforms which are considered distinct enough to receive separate names, there are, in all, some fourteen distinct named Japanese Primulas, although, as usual, all botanists are not prepared to accept this enumeration. Of those which are in cultivation, the pride of place must be given to two species, both of which have become highly important garden plants. These are *Primula japonica* and *Primula Sieboldii*, the latter often known as *P. cortusoides amoena*, though not a form of *P. cortusoides* of Linnæus, which is not Japanese. No fewer than eight species of Professor Bayley Balfour's arrangement of the Primula species are represented in the few Japanese Primulas. Taking in alphabetical order, and dealing with *P. Sieboldii* under its proper name, we come first to

Primula eximia (Greene).—This belongs to the *nivalis* section, one containing many charming Primulas, though represented in Japan solely by this, which is a microform of *P. nivalis* (Pallas). It is a sturdy, robust little plant, with flowers of a good size when compared with the plant itself. The authority for the name is Greene, in "Pittonia," III. (1897), page 251. This Primula is glabrous and has oblanceolate or oblong spoon-shaped leaves, which are entire or minutely crenated, acute or obtuse, and on short petioles. They

are without farina. The robust scape rises well above the leaves, and bears an umbel of from six to ten flowers of a purple colour. It occurs in the Kurile Islands, and also extends into the Aleutian and Pribilof Islands. It is desirable that this plant should take the place which the typical *P. nivalis* fails to fill properly in our gardens.

P. japonica (A. Gray).—Described by Asa Gray as far back as 1857, it was not until 1871 that this now indispensable Primula was introduced into our British gardens through the enterprise of Mr. William Bull. It is impossible to overpraise this handsome plant, whose tiers of whorled flowers are so effective in the garden. It is

THE WHITE-FLOWERED JAPANESE PRIMULA: *P. JAPONICA* ALBA.
THIS LIKES MOIST SOIL AND SEMI-SHADE.

naturalised in many places in the more open woods and by the sides of streams and ponds, and is one of the most valuable of all the hardy Primulas. A large colony in flower is a sight well worth seeing. It varies considerably in colouring, but the dark purple form is still the best. The colours range from deep purple to pink, rose, and almost pure white, though in the purest varieties I have seen there is always a coloured ring round the eye. The so-called improved varieties are no improvement. I have seen hybrids of *P. japonica* crossed with *P. Bulleyana*, but these are of no use, being simply both parents practically spoilt—*P. japonica* with only

a slight trace of *P. Bulleyana*. It is a native of Central and Northern Honto, Yezo, and is also cultivated in Japanese gardens. It is unnecessary to give cultural directions, as it will thrive almost anywhere, although preferring a moist soil and a shaded or semi-shaded position. It comes freely from seeds.

P. Kisoana (Miq.).—Why this has not been in cultivation in this country is rather a mystery. It has been grown in Japanese gardens for more than 200 years. Pax refers it to the section Fallaces, but undoubtedly Professor Bayley Balfour is correct in placing it among the Cortusoides. It has petiolate leaves, which are rounded, heart-shaped, also crenate or lobed, while the whole plant is practically villous-pubescent. The scape bears from two to five flowers of a deep rose colour. It should prove quite hardy in this country. A native of South-West Japan.

P. modesta (Bisset et Moore).—*Primula farinosa* is represented in Japan by two plants, although that known as *P. Fauriæ*, Franch., is really only a xeromorph of the above, which is, therefore, sufficient to notice at present. Pax considers *P. modesta* only a subspecies of *P. farinosa*, which it closely resembles; but the farina is golden instead of silvery. It is as hardy as *P. farinosa* or *P. frondosa*, and loves a moist situation. The flowers are purplish. From Yezo to Shikoku, and introduced to cultivation in 1911 by the Royal Botanic Gardens, Edinburgh.

P. Reinii (Franch. et Sav.).—Although not very widely known, the beautiful little Primula Reinii of the Fallaces section of Pax and the Reinii of Balfour has been in cultivation for some years. Its hardiness has not been fully tested, but it deserves a trial at the hands of lovers of the race. It has petiolate, hairy foliage, rounded or kidney-shaped, cordate at the base, with scapes a little longer than the leaves, and bearing an umbel of from two to six pale violet flowers, which are large for the size of the plant. With me this Primula is not hardy in the open, but I can manage it in a cold frame. The section Reinii is marked by the petiolate-rounded leaves, small calyces and cylindrical capsules, protruding beyond the calyx.

P. Sieboldii (E. Morren).—A great deal of confusion exists in gardens regarding the name of this plant. It is frequently sold as *P. cortusoides* or as *P. c. amoena*. *P. cortusoides*, as already mentioned, is not Japanese, but Siberian, and extends in Nature from the Urals to the Altai. This and *P. saxatilis* have adpressed calyx segments, while those of *P. Sieboldii* are patent. *P. Sieboldii* has been in cultivation in Japan for very many years, and it was known to the botanists of Europe in 1838, when it was described under the name of *P. cortusoides* variety *patens*, Turcz., by Turczaninow. In 1873 a cultivated plant was described by Morren under the present name

of *P. Sieboldii*. It had been grown in British gardens before that time, but the date of its introduction is doubtful. It was, however, sent from Japan to Messrs. James Veitch and Sons by their collector, Mr. I. G. Veitch, in 1861, under the name of *P. cortusoides*. Its natural habitat appears to be in moist meadows, but it is best known as a cultivated plant. Its flowers vary greatly, not only in colour, but also in size and form. The colours range from white to rose and purple, and the shape of the blooms is extremely varied, some being rounded and others deeply lobed. It is an easy species to cultivate, but is sometimes lost in winter from the dormant crowns being overlooked when the garden is being cultivated. It is generally hardy. There are numerous garden varieties of *P. Sieboldii*.

Other Japanese species of *Primulas* are *P. Jesoana*, Miq., an unintroducted species allied in appearance and in its botanical features to the other *Primulas* of the *Geranioides* section. It is reported to be of little attractiveness. *Primula tosaensis*, Yatabe, of the *Reinii* section, will hardly prove hardy in this country. Some of the Japanese *Cuneifolia* section, comprising *P. cuneifolia*, *P. hakusanensis*, Franch.; *P. heterodonta*, Franch.; and *P. nipponica*, Yatabe, are in cultivation. *P. macrocarpa*, Maxim., is of purely botanical interest. *P. Miyabeana* (Ito et Kawakana) is from Formosa and close to *P. japonica*, but has not been introduced here. JOHN MACWATT.

Morelands, Duns.

A BEAUTIFUL HABERLEA.

UNTIL a few years ago only one *Haberlea* was known to cultivation, viz., *H. rhodopensis*, native of the Rhodope Mountains. This plant the writer has seen growing in large patches, mingled with the pure white form, in cool, shady places near to the Shipka Pass in Bulgaria. It is an exquisite plant, and the flowers resemble those of the *Streptocarpus*, to which it is related, for both plants belong to the Natural Order Gesneraceæ. *Ramondias*, however, are much closer relatives to the *Haberleas*, and they succeed under similar conditions, viz., on shady banks, packed between rocks and given a fairly leafy compost. The new *Haberlea* named *Ferdinandii-Coburgii* is a grand acquisition to the genus, and it was deservedly granted an award of merit by the Royal Horticultural Society when shown in the early summer of 1911 by Mr. G. Reuthe, Keston, Kent. As may be seen in the accompanying illustration, it has medium-sized, round leaves, and a very free-flowering habit. The flowers are of a bright rosy colour tinged with pale purple blue and deeply spotted in the throat. It is hardy, and worthy of a place in those gardens where little-known alpine plants are cherished. In many gardens *Haberleas* and *Ramondias* are grown with a fair amount of success between vertical rocks. In nature it is supposed that the rosettes of leaves which lie flat against the rocks are thus protected against injury by falling debris from above.

G. Q.

HARDY FLOWERS FOR VASES.

SOME USEFUL HINTS.

THERE is a feeling against hardy flowers for vase furnishing, for which there is no good reason. Over and over again I have been assured that border flowers and wild flowers are wanting in long-standing properties, and that the tender foliage and flowers of shrubs and trees are equally singularly unsatisfactory in that respect. I use all manner of things so long as they are pretty, and by taking a few precautions have no cause to join in the cry against any of these. I have been using the loveliest twigs and branchlets of Morello Cherries, *Prunus Pissardii*, white-flowered Transcendant Crab and Tower of Glamis Apple, as

Lay them in a basket for half an hour and afterwards let them lie on a table till the time to arrange them comes, and it is no wonder that they last for only a short time, and sometimes fail to ever look up or assume their pristine brightness. So important is it that some kinds be placed in water that it is worth while to carry a pail of water and immerse the stems in it as soon as they are cut. Wild flowers need much the same treatment; at any rate, they should be carried home without delay and the stems plunged into water, preferably warm water, till they can be arranged. Some flowers require to be plunged or floated entirely in water. Of such are the beautiful *Helleborus* species, so useful in spring. Improperly treated, these droop at once. In even a few hours they become eyesores; whereas, when thrown into a tank of water and left at least twelve hours till the cells are surcharged, they last

HABERLEA FERDINANDII-COBURGII, FLOWERS BRIGHT ROSY BLUE.

well as of Apples of various shades of pink, though I find the pretty *Pyrus floribunda* rather fugacious and the buds prettier than the flowers. *Deutzias* are now in, *Banksia* Roses in long sulphur ropes, and *Spiræa van Houttei* and others, with bronze-leaved Oaks and thinnings of coloured Rose shoots.

Exceedingly beautiful are the single Tree *Pæonies*, which range in colour from white to crimson and salmon-tinted flowers of exquisite beauty. These and many others last well if, when cut, they are with the least possible delay plunged deeply into water. But what usually occurs is to carry them about or lay them down long enough for the sap to have evaporated so much that incipient withering sets in, after which the chance of the flowers and foliage lasting is reduced to the limit. Exactly the same thing happens with border flowers

a week. I have known them to stand in a cold room for a fortnight if given a second immersion.

There is yet another important point to be observed in selecting border flowers; that is their age. I once used a quantity of *Michaelmas* Daisies to decorate a church, and was warned that they would not stand over the Sunday. The lady who had gained this experience with *Asters* had forgotten to choose young flowers or those that had not been fertilised by insects, and so it happened that those she deprecated the use of, being young, stood perfectly, though they had the extra compensation of having been plunged in water for hours after picking. The advantage of using only young flowers has frequently been noticed, and with bulbous plants it is usually carried out. R. P. BROTHERSTON.

ROSE-GROWING IN TOWN GARDENS.

NOTES ON EXHIBITING.

Shading.—Rose shades are usually made of material that is impervious to light, but it is a mistake to imagine that all blooms will improve in colour from being kept in the dark. Many varieties will only attain their full colouring under the direct rays of the sun. Generally these are in the Tea class, or closely allied to it, Roses which have sprung from natives of a warmer clime. They are impatient of wet and frequently slow in opening, so that they need protection rather than shading. Excess of sunshine will completely spoil the colour of many other kinds, such, for instance, as some of the Pernetiana type, those of delicate shades of yellow and pink, and most of the red Roses. In the case of these it is well to supplement the shades by gumming tissue paper round the rims, allowing it to project a few inches underneath. A great deal may be done with the shades to retard a Rose's development, often a matter of importance at show-time; but in judging beforehand the length of time a bloom will take to expand, the exhibitor has one of his hardest tasks, and this can be learned only by studying the habits of each individual kind, noting whether it is slow or quick in unfolding its petals, and then, as often as not, a change in the weather will upset all one's calculations. As the blooms expand, greater care in spraying becomes necessary. Insecticides should be avoided temporarily and green fly removed by hand. On warm evenings syringing overhead with lukewarm water is very beneficial, but this is not advisable when the weather is cold. The hoe must be kept constantly at work, and this should always be the Rose-grower's chief implement.

Tying and Dressing the Blooms.

In the dressing of the blooms many points may be gained or lost, and the would-be exhibitor should practise it as much as possible some time in advance of the exhibition. The first step is to tie the flowers round the centre with white wool, the kind that is known as double Berlin being the best for this purpose. It should be cut into lengths of about nine inches, and the fastening is done by a double twist of the wool, which prevents it from slipping and allows of it being loosened when necessary. On no account should it be knotted. Generally speaking, it is of no use to keep a bloom tied for more than three or four days; but this depends upon the variety and the weather. In a hot spell many Roses will fly open and become useless in three days, which during a cooler period might often be kept in good form for a day or so longer. Full flowers may sometimes be restrained for a week. The more backward blooms will be tied only a day or two before the show, and most of

these will assume a better and more natural shape if the guard petals are allowed to fall before the ties are placed in position round the second row of petals. Others it may not be necessary to tie at all, but these will be slow-opening kinds which are just caught right and can be trusted not to "fly." Experience is the best guide, and the grower should study his Roses and practise with them before the show-time arrives. The actual dressing of the blooms is performed on the show bench after the tie is removed, the last thing before the judging.

It ought to be done with a large camel-hair brush, and should consist mainly in arranging the outer row of petals. These ought to be gently pushed

PRIMULA FARINOSA GROUPED IN THE ROCK GARDEN SHOWN BY MR. J. WOOD AT CHELSEA LAST WEEK.

back, but on no account should they be turned inside out in an endeavour to keep them open, as is sometimes done. This is "overdressing," and should disqualify a bloom. The arrangement of the boxes must be carefully thought out, care being taken to afford as much contrast as possible by keeping apart Roses of similar colouring. Dark reds are always valuable, and these are usually scarce; but one or more should be included if possible, even if of slightly smaller size than others that are available. The largest blooms must be in the back row, the smallest in front. As many spare blooms as possible should be taken, so that those which show a split centre may be discarded.

P. L. GODDARD.

SOME GOOD ROSES WITH FULL FLOWERS.

WHILE it must generally be admitted that a large majority of the newer Roses are of very wonderful colouring, and are most beautiful from an artistic point of view, it is also a fact that a great many of them are what one might call "thin" in build; that is to say, the petals are few in number. These thin Roses are very useful when used for massing in large beds, where the individual bloom is not of so much account as is the general effect produced by the mass, and they are also very lovely in the bud stage; but I have found that there are many Rose fanciers, especially among those with limited space at their disposal, who will have nothing to do with this class of Rose, and will only cultivate those varieties which might be termed "solid." A bloom of one of these more double Roses will keep shapely for a very much longer period than the thin type, either on the bush or when cut. To search through Rose catalogues in quest of these varieties with good lasting qualities is not only a long and tedious task, but often ends in utter failure, growers being disappointed to find that many a so-called double Rose turns out to be far from "solid." Such searchers will, I hope, find the following list helpful and reliable. All the varieties mentioned are good garden Roses and strong growers.

Mrs. Foley Hobbs, one of the finest recently introduced Teas, bears large and perfectly formed flowers of delicate ivory white, and is very free both in growth and flowering.

Molly Sharman Crawford (T.) is in the bud a delicate eau de nil white, and pure white in the full bloom. A good upright grower with beautiful foliage.

Mayflower (H.T.) is one of the best of the newer cream Roses, the pink tints suffusing the petals giving it a charming effect.

Excellenz M. Schmidt Metzler is a grand addition to the snow white Hybrid Teas, the blooms being of wonderful size and quality.

Entente Cordiale (Pernet-Ducher, H.T.) is a lovely creamy white, tinted with carmine. It is rather small in growth, but quite hardy and remarkably free-flowering.

Wm. R. Smith is a vigorous-growing Tea of great beauty. It is creamy white, tinted with pink and violet.

Mrs. Arthur Munt (H.T.) is very similar to the foregoing, but a little deeper in colour, especially in the autumn, when it is often quite a deep peach.

Mrs. Harold Brocklebank (H.T.) is a most persistent bloomer of good upright habit. The blooms are creamy white, the outer petals tinted

salmon rose and the centre buff. One of the best garden Roses.

Alexander Hill Gray (T.) is the best of the newer yellow Teas, being most prolific and a fine grower. The rich lemon yellow flowers deepen as they expand.

Natalie Bottner (H.T.), called by some the Yellow Druschki, is, I am glad to say, much fuller than its namesake. The soft creamy blooms are very pleasing, but open badly in damp weather.

Miss Alice de Rothschild (T.) is well described as a dwarf Maréchal Niel, the deep citron yellow blooms being very similar to that old favourite Rose.

Sunburst has, since its introduction in 1912, won a great name for itself. In colour it is variable, some blooms being very light cadmium yellow, while others are deep orange yellow, either shade being very beautiful. The blooms are exceedingly long.

Frau Oberhofgartner Piecq (H.T.) is a new yellow Rose of great merit, and as an exhibition flower will be sure to make good headway, the golden yellow Hybrid Teas being hard to find.

Duchess of Normandy (H.T.) is a salmon flesh sport of Dean Hole, and as an all-round Rose should win as good a reputation as its forbear.

Mrs. Geo. Shawyer is a fine, vigorous Hybrid Tea of great value. The clear rose-coloured flowers, although very large and full, are carried on erect stems.

Margaret (H.T.) should be in every Rose-lover's garden, for the clear soft pink flowers are perfect in every way and produced in profusion. It is an ideal town Rose. [We find this mildews badly.—ED.]

Desdemona (H.T.) is a decided advance in the light pink section, the rosy opaque flowers being very large and full.

Countess of Shaftesbury (H.T.) is, I think, one of the most lovely pink Roses. The exquisitely formed silver pink blooms are invaluable for cutting, and are produced in abundance the season through.

Duchess of Westminster, a clear madder rose, sometimes attains to a remarkable size of bloom, and is a very distinct novelty.

St. Helena (H.T.), besides being of good size and form, is sweetly scented. The upright flowers are pink on a cream ground, and are very handsome.

Lady Alice Stanley (H.T.) is a grand bedding variety. The coral rose blooms are produced in clusters, but each is of large size and good shape.

Mrs. Wallace H. Rowe (H.T.) is of very novel and distinct colouring, being a peculiar mauve, but very pretty.

Jonkheer J. L. Mock (H.T.) is a finely built Rose with very high centre. The petals outside are bright cherry red, inside silvery white, and when true to colour it is most effective; but, unfortunately, it often comes very dull, and is, in fact, quite disagreeable.

G. C. Waud (H.T.) is a most brilliant Rose, a glowing orange vermillion, and its colour is very lasting.

George Dickson (H.T.) is a truly marvellous Rose. The velvety black crimson blooms are of immense size and finely built. Its only fault is that it hangs its head.

Earl of Gosford (H.T.) is in general appearance not unlike the old favourite Victor Hugo, the heavy black shadings on the crimson ground making it a very striking bloom.

Essex.

W. A. E.

NOTES ON VIBURNUMS.

THE Japanese Snowball Tree (*Viburnum plicatum*) is now flowering to perfection in many English gardens. A large bush clothed with clusters of white flowers resembling those of the Guelder Rose is indeed a wonderful sight. It is easily one of

VIBURNUM RHYTIDOPHYLLUM, A RARE HARDY SHRUB FROM CHINA. IT BELONGS TO THE GUELDER ROSE FAMILY

the six most beautiful shrubs for English gardens. There are other delightful members of this family, and of them our native Wayfaring Tree is one of the most popular. It is often seen in the wild state scattered here and there on the outskirts of the woodland or as a roadside shrub. It is common in our hedges, but none the less beautiful, and grows freely in almost any soil, especially on hillside overlying chalk.

From Central China comes the little-known *Viburnum rhytidophyllum*, destined to be a very popular wall shrub in the course of time. The creamy white flowers are borne in large heads during May. The illustration on this page shows a remarkably fine plant flowering freely on a south wall at Kew. In the same garden it has been grown in open beds, but here the result is not nearly so satisfactory.

THE BEST CONIFERS FOR LAWNS.

IN the pure air of the country, where soil and climatic conditions are alike favourable for the growth of conifers, a number of species may be included among the most useful trees for lawn specimens. They grow vigorously, form shapely plants, and the leaves of the evergreen kinds are attractive throughout the year. Ideal conditions for conifers are found in the South and West Counties of England, throughout Wales, the greater part of Scotland, and Ireland. Anywhere, in fact, where the ground is naturally moist and climatic conditions are on the moist side and the atmosphere is pure, they may be expected to succeed.

But there are places where the conditions are less favourable, and still good coniferous trees are grown, as may be seen in the drier parts of the Eastern Counties. The most unsatisfactory conditions are impure atmosphere and very heavy and chalky soils. Anyone who is intimate with the climatic conditions of such counties as Devonshire and Perthshire will recognise at once the peculiarities of climate which tend to produce the best conifers. A mature

Cedar of Lebanon is always recognised as a decided asset to a large garden, especially when the garden surrounds an ancient house; but, unfortunately, such trees have sometimes been placed in positions where they interfere with the building or are crowded by other trees. This being the case, anyone who contemplates planting such a wide-spreading tree should ascertain first that it will have sufficient room to develop to its

PRIMULA SECUNDIFLORA, A BEAUTIFUL NEW HARDY SPECIES FROM CHINA. IT HAS WINE-RED FLOWERS.

fullest extent without crowding other subjects. But planters would be well advised to select the glaucous variety of the Atlas Cedar (*Cedrus atlantica glauca*) in preference to the Lebanon Cedar, for it is a decidedly more beautiful tree, especially when young. The Deodar (*C. Deodara*), too, is a suitable tree to plant in the Southern Counties, but is generally less hardy than the other kinds.

The Incense Cedar (*Libocedrus decurrens*) is another decorative tree. Its beauty, however, centres in its stiff, columnar habit. It takes up little room, but its full beauty can only be seen when it stands quite clear of other trees. It may attain a height of 40 feet or 50 feet.

The Douglas Fir (*Pseudotsuga Douglasii*) and its glaucous-leaved form grow into majestic trees 70 feet to 80 feet or 100 feet high, furnished with branches from base to summit, in those places where suitable conditions prevail. But they must have shelter, otherwise their tops are liable to be broken. The bottom or lower slopes of a moderately deep valley often offer an ideal home. Such trees must be given ample space, for they are only seen at their best when standing quite clear of other vegetation.

The Redwood of California (*Sequoia sempervirens*) is another tree which is only seen at its best when planted in a sheltered situation with

a golden colour. For this reason it is called the Golden Larch. Another handsome deciduous conifer is found in

The Maidenhair Tree (*Ginkgo biloba*). This grows quite 70 feet high, and is easily recognised by reason of its wide, flat leaves, which bear a resemblance to a gigantic pinnule of a Maidenhair Fern.

Saxegothea conspicua is only suitable for the warmer parts of the country, but in the few places where it thrives it forms a remarkably handsome plant. Of very graceful outline, the branches are well clothed with Yew-like leaves, which are less sombre in appearance than those of the common Yew.

Cupressus lawsoniana forms a beautiful tree when placed in an open position, while many of its varieties are equally, if not more, attractive. Good ones are *glauca*, *Silver Queen*, *intertexta*, *gracilis aurea* and *lutea*. The juvenile or *plumosa* forms of *C. pisifera* are also very beautiful, *plumosa aurea* and *sulphurea* being very suitable for small gardens. The true Cupresses, such as *Cupressus sempervirens*, *C. lusitanica*, *C. macrocarpa* and other kinds, are all fine trees when at their best, but they are only suitable for the warmer counties.

Thuya plicata, or *T. gigantea* as it is often called, usually grows into a shapely specimen, although there is a tendency for the branches to

plenty of room for development. Its irregular outline fits it better for garden decoration than the more formal, conical habit of *S. gigantea*. A position for the latter tree needs selecting with considerable care. As a rule, a sheltered corner somewhat apart from the lawn is more suitable than a conspicuous position.

The Umbrella Pine of Japan (*Sciadopitys verticillata*) is well fitted for a position where space is limited, for it grows less rapidly than many other kinds and takes many years in attaining a height of 20 feet. Its deep green, flat leaves are arranged after the fashion of the ribs of an umbrella; hence the common name.

Pseudolarix Kämpferi is a rare tree with deciduous leaves. Its light green foliage is conspicuous throughout the summer, but is most attractive during the autumn, for at that period it turns to

become thin about the top. *T. orientalis*, on the other hand, forms a dense bush or tree up to 20 feet or more high. The best of the

Hemlock Spruces for general planting is *Tsuga mertensiana*. It is of vigorous habit and graceful outline, and succeeds throughout the country. *T. pattoniana* and *T. brunoniana* are also very beautiful trees, but their culture must be restricted to the warmer counties. Among the Spruces, the blue or glaucous leaved form of *Picea pungens* is one of the most beautiful. It is quite hardy, but is sometimes attacked by a leaf-casting disease. Other decorative Spruces are *P. Omorica* and *P. Morinda*.

The Firs or Abies offer many representatives. *A. amabilis* and *A. nobilis* are very showy when at their best, but they are subject to a disfiguring disease which frequently cripples them to a serious extent. *A. lowiana*, *A. concolor*, *A. brachyphylla* and *A. Pinsapo* are all decorative kinds.

Among the Pines, *Pinus Pinea*, *P. excelsa*, *P. Cembra*, *P. Coulteri* and *P. ponderosa* may be selected as a representative set. D.

VIOLA GRACILIS BLUEJACKET.

BLUEJACKET is the deep blue form of *Viola gracilis*, differing from the purple blossoms of the typical *gracilis* in a truly delightful manner. The flowers are, if anything, even smaller than *gracilis*, being identical in size and in habit of growth to the exquisite little sulphur yellow *Marjorie*, which is becoming such a favourite garden subject. The deep blue of Bluejacket contrasts exquisitely with either *Marjorie* or *Golden Fleece* (a deeper yellow form), and as it produces its flowers just as profusely, there is no reason why it should not be as freely used as the type. We use it in quantity here in the gardens at Holland House and like it immensely, and purpose raising a large stock for spring bedding as well as for further decorative effects on the slopes of the rock garden. Such floriferousness, allied with the dwarf tiny foliage and the large Violet-like blossoms, combine to make Bluejacket an ideal spring flower. It is truly perpetual; summer drought has no terrors for it, for plants burnt down to the ground-level in a dry season will come up fresh and green with the early rains and re-establish themselves in readiness for another flowering season.

PRIMULA JAPONICA SANGUINEA.

THE true sanguinea variety of *Primula japonica* seems even now to be a somewhat scarce plant in gardens. At its best it is fully equal to the grand *P. pulverulenta* for effect. It is not quite so graceful as *P. pulverulenta*, but the colouring is so rich and brilliant that it would be well if this sterling *Primula* was grown in very large quantities. Even if only a small grouping is secured for a water-side effect or for a cool spot elsewhere in the garden, *sanguinea* will prove a very attractive subject. It would be a good thing for the popularity of the best forms of *P. japonica* if all the poorer and mottled varieties and seedlings were entirely swept out of gardens, leaving a clear field for the superior selected self colours. If one could ensure that the best pink, rose, scarlet-red, and crimson shades were selected and perpetuated and all the inferior forms discarded, then *sanguinea* and the other rich forms of *japonica* would rise to a higher level in garden appreciation, and we should get more of the beautiful *Primula* colour drifts which are such an acquisition to the informal garden.

Clacton-on-Sea.

P. S. HAYWARD.

NEW AND RARE PLANTS AT THE CHELSEA SHOW.

FIRST-CLASS CERTIFICATE.

Adiantum grossum.—A handsome evergreen sub-erect species from Tropical America, which, comparatively, might be referred to *A. macrophylla*, with much more rounded pinnæ. The exhibited example was nearly two feet high, displaying vigour and freedom of growth. From Messrs. H. B. May and Sons, Edmonton.

AWARDS OF MERIT.

Platyserium Cordreyi.—By reason of the rarity of garden forms of this genus, apart from the intrinsic merit of the variety, this would appear to have deserved "first-class" rank, an honour probably yet in store. It has been evolved from *P. Alciorne*, the hoary fronds of 2 feet or more in length considerably ornamented by the deep fingered lobes at their apices. We regard it as an acquisition as well as an addition to the Fern tribe.

Pteris flabellata plumosa.—This, if not of the plumose density of some of the *Nephrolepis*es, is at least a remarkable variation, and if sporting should follow, might prove invaluable to the gardener and decorator. These came from Messrs. H. B. May and Sons, Edmonton.

Calceolaria Stewartii.—This is a golden yellow flowered variety, its outstanding features freedom of blossoming and the hall-mark of general utility. As exhibited, the plants were not more than 1 foot high, the pouches of comparatively large size. From Messrs. James Veitch and Sons, Chelsea.

Adiantum gloriosum Lemkesii.—Obviously a Farleyense form with more crested pinnæ, the mass of young fronds rising from the centre of the plant being coloured a warm reddish tone. A graceful and beautiful variety, of which a nice group was on view. Shown by Messrs. Lemkes and Sons, Alphen, Holland.

Campanula tomentosa Maud Landale.—A pretty variety of this biennial Bell-flower, the bluish erect bells appearing from the axils of woolly stems and leaves. Shown by Miss Maud Landale, Limpsfield.

Begonia Lady Carew.—A double-flowered, tuberous-rooted variety, having rose-coloured flowers in huge rosettes of 6 inches or so across. The shade of colour is very bright and effective. From Messrs. Blackmore and Langdon, Bath.

Primula secundiflora.—A remarkably beautiful novelty discovered by Mr. Forrest when collecting in China for Messrs. Bees. It was found on the Lichiang Range at an altitude of some 13,000 feet, and the photographs taken by Mr. Forrest on the spot depict a plant of considerable freedom of flowering. Botanists look upon it as identical with *P. vittata*, but it is quite distinct from the plant usually recognised as such, and vastly superior. For gardening purposes and to give our readers an idea of the plant, it might not inaptly be compared to a red-flowered *P. sikkimensis*, the colour a rich wine red. It is a moisture-loving plant. Shown by Messrs. Bees, Liverpool. See illustration on page 284.

Oxalis adenophylla.—This charming species, with many-lobed, glaucous leaves and rose-coloured flowers, was shown by Messrs. Bees, Liverpool, and Mr. G. Reuthe, Keston. It is one of the choicest of rock garden plants, meriting all care.

Pinguicula reuteriana.—A delightful novelty from the Alps of Dauphiny. The peduncles are

4 inches or so high, one-flowered, the rosy pink lined flowers pretty in the extreme. From Mr. G. Reuthe, Keston, Kent.

Carnation Scarlet Carola.—This is a counterpart of the original crimson variety in all save colour, which is self-descriptive. It is a bold and striking variety. From Mr. C. Engelmann, Saffron Walden.

Iris Gold Crest (*I. pallida* × *I. Cengialti*).—The greater leaning of the variety is towards the first-named parent, the flowers somewhat modified in size and more compactly built. The colour, a bright, lustrous violet blue, is very fine; the gold beard or crest, which justifies to some extent the name, very pronounced. Raised and exhibited by Mr. W. Rickarton Dykes, Charterhouse, Godalming. See illustration below.

Clematis Empress of India.—A very beautiful addition to the race. The handsome flowers are coloured a rosy mauve with lilac shading. Doubtless in the open the richer colour would be enhanced. From Messrs. George Jackman and Sons, Woking.

Telopea speciosissima (Waratah).—A handsome inflorescence of this rarely seen Australian shrub was shown by the Rev. A. T. Boscawen, Ludgvan Rectory, Long Rock, Cornwall. The flowers, arranged in a dense, conical head, are tubular and coloured a reddish scarlet, the crenated leaves not unlike those of *Ardisia crenulata*, but longer and even more coriaceous and shining. Its flowering in this country is somewhat rare. A cultural commendation was also awarded to the exhibitor.

Pittosporum Mayi Silver Queen was exhibited by the Donard Nursery Company, Newcastle, County Down. It is a pretty variety, with silvery variegated foliage shown to advantage against the almost black, wiry stems.

NEW ORCHIDS.

First-Class Certificates.—*Miltonia The Barons* and *Miltonia J. Gurney Fowler*, both shown by Messrs. Armstrong and Brown, Tunbridge Wells; *Odontoglossum Queen Alexandrina*, from Messrs.

Charlesworth and Co., Hayward's Heath; *Miltonia vexillaria Solum* and *Miltonia vexillaria Lælia Sander*, both shown by Messrs. Sander and Sons, St. Albans; *Lælio-Cattleya Medina Excelsior*, exhibited by Messrs. Flory and Black, Slough; *Lælio-Cattleya haroldiana Bronze King*, from Messrs. S. Low and Co., Enfield; *Miltonia Princess Victoria Alexandra*, from M. C. Vuylsteke, Ghent; and *Odontioda Bradshawia Perfection*, shown by Messrs. J. and A. McBean, Cooksbridge.

Awards of Merit.—*Brasso-Cattleya shilliana* and *Odontoglossum Chanticleer*, from Messrs. Armstrong and Brown, Tunbridge Wells; *Lælio-Cattleya Fascinator Mossia Purity*, *Odontoglossum Dusky Monarch* and *Lælio-Cattleya Sunstar*, shown by Messrs. Charlesworth and Co., Hayward's Heath; *Odontonia Roger Sander* and *Cattleya Magali Sander*, exhibited by Messrs. Sander and Sons, St. Albans; *Cymbidium Venus*, from Messrs. Stuart Low and Co., Enfield; and *Miltonia Adonis* and *Odontioda Prince de Galles*, shown by M. C. Vuylsteke, Ghent.

IRIS GOLD CREST, A CHARMING NEW HYBRID SHOWN BY MR. W. R. DYKES.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Late Peach Trees.—The fruits on these trees require their final thinning. Select the fruits which are best placed with regard to sun, and remove some of the leaves from those which it may be necessary to leave under the wires. The aim of the cultivator should be to leave the fruits evenly distributed over the tree and as many of them on the upper side of the tree as possible, and due regard must be paid to the nature and condition of each tree in deciding how many fruits they are to carry.

The Orchard-House.—Apple and Pear trees in pots require careful attention. The pots have now become well filled with roots, and consequently more water and stimulants will be necessary. Examine them several times daily, and give sufficient water when necessary to thoroughly soak the ball of soil. As soon as the crop is sufficiently advanced, a careful thinning of the fruits should take place, removing all deformed and worthless fruits first.

Plants Under Glass.

Pot Roses.—Most of the plants will have finished flowering, and should be removed to their summer quarters, where the pots may be half plunged in ashes at a sufficient distance apart to permit sun and air to pass freely among them. It often happens that these plants are neglected after the flowering period is over, and consequently the flowers are of an inferior quality the following season. Give frequent waterings with liquid manure, and keep a sharp look-out for aphid and mildew, which must be checked as soon as possible. The buds should be removed from all shy-growing plants, in order to build them up and prepare them for next season's forcing.

Calceolarias.—These are valuable plants for the conservatory, and to have them in flower early it is necessary to sow the seeds about this date. Sow in well-drained pans of fine soil and cover the seeds very lightly. Cover the pans with sheets of glass and place them in a close, cool pit. When the young plants are through the surface, they must be placed quite near the roof glass, but never be exposed to the full glare of the sun. Pot as soon as large enough, and never allow them to become pot-bound until they are placed in their flowering pots.

Humea elegans.—Now is a good time to sow seeds of this beautiful plant for the decoration of the conservatory or flower garden the following season. Sow in light, sandy soil and protect from sun.

The Flower Garden.

Sweet Peas.—The latest batch of plants which have been raised in pots should be planted out as soon as possible in ground which has been thoroughly prepared for them, and a sowing may be made in the open garden to produce blooms in the autumn. The early batch of plants will benefit by mulching with decayed manure.

Mignonette.—A good sowing should be made now to produce blooms in August and September. Sow in a cool position and make the soil moderately firm. When the plants are large enough to handle, they should be freely thinned, and they must never be allowed to suffer from want of moisture at the roots.

Climbing Plants.—Attend to the requirements of all climbing plants at regular intervals, keeping them well thinned out so that those which remain may be trained in a free and natural manner. Clematises and Loniceras are among the first to become entangled, and, unless they are kept well within bounds, they will soon be ruined for the season. Climbing Roses must also be kept well thinned out, and the shoots from the base of the plants secured in such a manner that they will not be broken by rough wind. Insect pests should be carefully watched for and destroyed as soon as possible. If dry weather prevails, a mulching of farmyard manure ought to be placed over the roots to prevent evaporation.

The Hardy Fruit Garden.

Cherry Trees.—Most of the trees have set a good crop this season, and in many cases the fruits

will require thinning if the finest quality is desired; but this should be carefully performed, and not too freely until the fruits begin to swell. Keep a sharp look-out for black fly, which is often troublesome, especially during cold weather. Maggots are also troublesome, and must be destroyed as soon as noticed. Do not allow the foliage to become overcrowded for want of disbudding. A good mulching of decayed manure may be given to trees which are exposed to the sun. As soon as the fruits begin to colour, protection from birds must be provided.

Early Strawberries.—The earliest plants growing on sheltered borders are now swelling their fruit, and they will benefit by a watering of weak liquid manure, which should be carefully applied to the roots without coming in contact with the fruit or foliage. If good specimens are desired, a careful thinning of the fruits must be done. Protect the crop from birds as soon as colouring commences.

The Kitchen Garden.

Peas.—To produce Peas throughout the autumn, weekly sowings should be made from this date to the middle of June, and, if possible, the ground for these sowings should have been trenched and manured for the purpose. Deep cultivation is the best means of avoiding mildew, which often proves troublesome during the autumn. The Pea is a gross-feeding plant, and should receive a liberal supply of moisture at the roots through August and September. The space between the rows should be mulched with farmyard manure. Distinction, Autocrat and Rearguard are good varieties for this purpose, and seldom suffer from the attacks of mildew. Midseason Peas should be staked as soon as the plants are a few inches high. Water and mulch freely if the weather is dry.

Early Carrots.—Let these be thinned as soon as possible, and keep the hoe at work between the rows. Sow again for use during the autumn. The latest batch intended to furnish supplies through the winter and spring may be sown about the middle of June. At Frogmore our largest sowing is made in June, and these roots generally escape the Carrot fly or maggot.

Vegetable Marrows may now be planted in the open and protected from frost or rough wind. Plants in pits should be kept well thinned out and watered freely with liquid manure.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Lettuce.—From this date sowings had better be made where the plants are to remain, as planting out the thinnings in hot weather entails a good deal of work in keeping them supplied with water. Care should be taken to sow thinly, and when the young plants are about three inches high, thin out to at least 9 inches apart. This will apply more particularly to the Cabbage sorts.

Peas.—In cold districts it will be advisable in sowing Peas from now till the middle of June to sow some of the earlier sorts. These late sowings are sometimes not very satisfactory, as they suffer from mildew, so that it will be necessary to give them a little extra care and attention. Select a piece of ground that is partially shaded from the direct rays of the sun, and see that they do not suffer from drought.

Carrots.—Maincrop Carrots will now require thinning, and, as advised for the earlier sorts, this work should be done in showery weather. Where wireworms and the Carrot maggot are troublesome, put some mowings from the lawn between the rows, and repeat this from time to time until all danger is past.

Kidney Beans.—The main crop should now be sown, and as this is naturally the most important, a good position should be selected. One of the great evils in the cultivation of this crop is overcrowding, and there is no occasion for it, as better crops are secured when the plants are allowed plenty of room. They should be given at least 2 feet between the rows, and thinned out to from 9 inches to a foot between the plants. Plants that have been brought on under glass may now safely be planted out.

The Flower Garden.

Sweet Williams.—There has been such a wonderful improvement of late years in the strains of these old-fashioned flowers that it is more than likely their popularity will be increased. Some of the self colours, such as Pink Beauty and Sutton's Scarlet, are particularly fine, and well adapted for planting in masses where colour effects are wanted.

Thinning Hardy Annuals.—Those that were sown last month should now be ready for thinning. It is of the utmost importance that they be thinned early and severely. If this is done, not only will the blooms be larger and finer, but they will last twice as long as those allowed to be crowded together.

Plants Under Glass.

Cyclamen.—Young plants from seed sown in August will now be ready for a shift into 4½-inch pots. Pot moderately firm in a compost of loam, leaf-soil and sand, with a sprinkling of bone-meal, and in doing so care should be taken not to damage any of the foliage. For a time after potting keep the plants shaded, and spray them over several times on fine days, as it is important that the foliage should always be moist. By the end of June they may be safely transferred to frames, keeping them well up to the glass, and by all means see that they are not subjected to draughts.

Perpetual-Flowering Carnations.—The plants rooted towards the end of last year will now be ready for potting into their flowering pots. For this potting use a good rich compost, in which only a small quantity of leaf-soil has been added, and pot rather firmly. After this potting place them in a cool house, and for a time very little water should be required; indeed, for a day or two a slight spraying with the syringe should suffice.

Indian Azaleas.—These will now have completed their growth and should be moved into cooler quarters. They must not, however, be placed out of doors at this time; indeed, if a convenient light structure is available, where they will get plenty of light and air, they had better not be put out at all.

Sowing Primulas.—The seed should only just be covered with fine soil or sand. Place the seed-pan in a moderate temperature and shade from the sun. Be careful to prick out the seedlings as soon as they can be handled, and put them back into heat until they are large enough to pot on.

Cinerarias.—Where the plants are not expected to be in bloom before March, the seed need not be sown before this date. Unlike Primulas, they resent a high temperature. Stand the seed-pan in a cold frame, and, if not exposed to the sun, it will not be necessary to shade them in any way.

The Hardy Fruit Garden.

Apples.—The fruits on the most forward of the young trees will now be sufficiently advanced so that they may be gone over and judiciously thinned. It is a great mistake to allow large clusters of fruit to remain on the trees, which will more than likely never make good specimens. It is far better to have a few good fruits than a score of indifferent ones that in the end will not be fit even for cooking. If time will permit, these young bearing trees will be greatly benefited by an occasional watering with liquid manure.

Fruits Under Glass.

Vines in Early Houses.—When the berries have finished colouring, the temperature should be reduced; indeed, fire-heat should only be used on dull days. Vines in succession houses will be coming on rapidly, and the houses should be closed down early in the afternoon to get the benefit of as much fire-heat as possible. On fine evenings the top ventilators should be opened slightly for a short time to clear excessive moisture.

Melons.—As the fruit is approaching the ripening stage, only sufficient water should be given to keep the plants from flagging. Air should be admitted top and bottom; this will add materially to the flavour of the fruit. Melons should be kept at least four days after being cut before being sent to the table.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)

INFORMAL FEATURES IN A GARDEN SCHEME.

SO wide is the geographical distribution of the exotic plants with which gardens are adorned at present that it is not surprising the old attitude of arranging them in stereotyped borders, if not wholly surrendered, has been at least modified to such degree that for these wildings of other lands a freer arrangement, both in garden design and in the system of grouping them, is being generally adopted. To this influence much of the present character of informal gardening is due. It seeks, beyond all things, to illustrate plant-life in its highest possible development, grouping them under conditions that approximate to those in Nature; and creates a sense of individuality in the garden scheme, investing it with a charm that would otherwise be non-existent. It is idle to suggest that a heterogeneous collection of plants indigenous to widely different localities can be accommodated under border conditions with the hope of permanent success; while apart from this consideration is the fact that a garden gains in interest and effect when the transition from one part to another is gradual and discloses by its occupants or arrangement that different conditions are illustrated.

Reasons such as these give distinction to rock, bog, water and other special gardens to which distinctive names have been given, indicating the prevalent type of plant-life for whose well-being they have been created. The principle underlying this idea is apparent, as, in the first instance, alpine and hill-loving plants are mentally associated with elevated ground and rock, and in reproducing these under artificial conditions we emphasise the most prominent features, choosing a more or less elevated position partly on account of the greater available light, and because such a position accentuates the apparent height. One may contend that the use of rock is only a fanciful idea, gaining its importance chiefly from the effect it produces; but its mechanical action in draining and conserving moisture in the soil is of far greater moment. Its pictorial aspect is only worthy of attention when it is carefully held subservient to, and gives forceful expression to, the living plants with which it is adorned. Some criticism of an adverse character is at times directed to the fact that in numerous instances rock gardens are accompanied by an accessory background in the form of trees or shrubs; but as these are salient features in any English landscape, it does not appear feasible to eliminate them. The additional element of truth that would accrue scarcely compensates for their loss, and when the taller arborescent growth does not encroach upon or overshadow the rock garden, its double function as shelter and background is always an asset of great practical value.

The transition from rock to water garden is rendered most natural by interpolating the bog garden between. Its drier portion, encountered directly on leaving the rock garden, will foster growth native to the open uplands and heath. By gradual descent moister conditions will unfold themselves, until quite sodden ground will occur in close proximity to, and at times be carried directly from, the margins of an open expanse of water, while natural conditions approximating to those indicated foster the widest range of exotic plant-life at no great expense beyond the initial cost. In their absence much may be done by

artificial means to render such a scheme feasible, either on a large or a small scale. One of the best agents for forming an impervious lining over porous soil is well-puddled clay, a material that is generally easy to procure and at no great expense. For open water, the ground after excavating should have the sides and bottom lined with clay to a depth of 6 inches to 9 inches, while ground intended for bog-beds should have a thickness of 4 inches to 6 inches puddled over the bottom and sides, care being exercised that the clay is not allowed to dry and shrink before the water and soil are given their respective positions.

Were the ground not too restricted, a happy expression would be to wed the water scheme on its northern limits to the woodland, and if some portions of the latter were partly cleared of the forest growth and the ground cleaned and manured, introducing wide belts of Primrose, Polyanthus, Forget-me-not, Doronicum, Arabis, Aubrietia, Iris, Lupine and Foxglove, with Tulips, Daffodils, Scillas, Muscaris, Snowdrops, Aconites, Ornithogalums, Camassias and allied subjects, a feature of unusual beauty and of perennial interest would be incorporated in the garden scheme. One would naturally be tempted to link this part up with the other garden features by introducing informal groups of wild Roses of this and other lands, and any of their numerous progeny that are free in growth and effective in flower. It would be easy to name Roses that would look natural if skirting the northern extremes of the bog ground, while sympathy with the rock garden would be expressed in *Rosa nitida*, *R. lucida*, *R. pyrenaica* and the prostrate-growing *wichuraiana* type. Gradually, as the rock garden passed from view and the more formal lines of terrace, parterre or mansion disclose themselves, a more orderly arrangement will prevail; and the transition from the informal or natural garden to that which is strictly formal is nowhere easier or more pleasantly united than by the aid of Roses alone.

Coombe Court Gardens.

THOMAS SMITH.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely

packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

TULIP BULBS FOR INSPECTION (H. L.).—The bulbs are perfectly healthy, but the plants have suffered from some check while they were growing. Probably they became too dry or were suddenly exposed to a different temperature from that to which they had become accustomed.

"FIRE" IN TULIPS (C. Q.).—The Tulips are badly attacked by the disease called "fire." This disease is usually very prevalent when the Tulips are exposed to cold winds or frosts during the growing period, and is also likely to be carried over from one year to the next by means of the resting bodies which the fungus *Sclerotinia parasitica*, to which it is due, produces. These resting bodies may be present either in the soil or in the bulbs just between the bulb scales or about the neck of the bulb. We find that protecting the young growths of the Tulip is a great aid in warding off the disease.

TREES AND SHRUBS.

SHRUB TO NAME AND TREATMENT (Mrs. A. T.).—The specimen sent for determination is the Bladder Nut (*Staphylea pinnata*), a native of Southern Europe. The red-berried Elder to which you refer is *Sambucus racemosa*, a shrub common throughout the Northern Hemisphere and plentiful in some parts of Switzerland.

PRUNING DOUBLE-FLOWERED GORSE (E. B. G.).—The double-flowered Gorse may be kept away by cutting it back as soon as the flowers are over. If it is kept pruned from the time it is 1½ feet high, there will be no need to cut it hard; but if it is allowed to become leggy, it will then need to be cut back into the hard wood. Although it usually breaks well from old wood, such is not always the case, and it is as well to avoid too severe pruning whenever it is possible.

TREATMENT FOR LILACS (H. M.).—Providing your Lilacs are healthy, you may cut them back safely in the manner you describe. The work should be done as soon as the flowers fade. Do not allow suckers to grow from the rootstock, however, for they will weaken the main branches. It is also advisable to keep the centres of the plants free from very weak shoots. An occasional application of liquid cow-manure may be given with beneficial results during the period of growth, and a surface-dressing of well-decayed manure above the roots will assist in the promotion of new growth.

THE GREENHOUSE.

ABOUT AN ASPIDISTRA (M. P. H.).—Either (1) the plant is in a draught, (2) the leaf sent is fading from old age, or (3) the soil is becoming poor. Try watering with a solution of sulphate of ammonia. As much as will cover a sixpence dissolved in a gallon of water may be used once a week.

FRUIT GARDEN.

RED CURRANT LEAVES (D. M. H.).—The Currant bush appears to be attacked by aphids, and should be sprayed with Quassia and soft soap.

MELON PLANT FOR INSPECTION (C. L. S.).—The browning of the Melon stem does not appear to be due to any insect or fungus attack, but looks more like burning or scorching.

INJURY TO RASPBERRIES (H. B. J.).—Your Raspberries are badly attacked by the Raspberry cane moth (*Lampronia rubiella*), the caterpillar of which bores into the young shoots and destroys them. If you cut away and burn the affected shoots now, you could do much towards destroying the pest outright.

MISCELLANEOUS.

THE LESSER STITCHWORT (C. P.).—The Lesser Stitchwort is *Stellaria graminea*, the two names being used together in Syme's "English Botany." It can be distinguished from the Greater Stitchwort by its narrower leaves and smaller flowers. The two can be easily separated. Both are quite common.

SWEET PEA LEAVES FOR INSPECTION (F. R.).—The yellowness of the leaves is a symptom of some mal-nutrition, but the material is insufficient to enable us to say what the precise cause of the trouble is, or whether it is in any way connected with streak (which we greatly doubt). Cold winds sometimes bring about an appearance such as the leaves show.

WATER AND CEMENT TANK (C. T.).—We have not experienced anything of a detrimental character resulting from the use of water from a newly made cement tank, and have known of several instances of Water Lilies being planted before the first water was run off. If, however, you fear to use the first water, let it stand for a few days and then let it run off. The differences between *Cheiranthus* and *Erysimum* are very small, and rest chiefly in the form taken by the cotyledons or seed leaves. In *Cheiranthus* they are usually accumbent and in *Erysimum* they are incumbent. Botanists are not agreed upon the point that the two genera should be kept distinct.

VARIOUS QUESTIONS (F. W. L. F.).—Before giving advice on the stopping of *Chrysanthemum* plants for the production of exhibition blooms, we should require to know which varieties you are growing. Usually, the natural break—which occurs on the majority of varieties

from the beginning of May to the end of June—gives the most desirable results. Naturally late-flowering sorts should have been stopped before this date. Plants intended to bear more flowers of smaller size for cutting should be stopped in April and again early in June. Yes; plant *Oxalis cernua* in the autumn. The name of the flower sent is *Clivia miniata*.

NAMES OF PLANTS.—*Zelie*.—*Paulownia imperialis*.—*C. H. F.*.—*Pyrus Torminalis* (the Wild Service Tree).—*Miss M. G. H.*.—*Raphiolepis ovata*.—*G. B.*, *Lympstone*.—*Ceanothus dentatus*. The plant described is a very fine specimen.—*J. D.*.—*Pyrus Aria* (White Beam).—*J. F.*, *County Durham*.—*Prunus Padus* (the Bird Cherry). It will grow freely in ordinary garden soil.—*H. C. C.*, *Limerick*.—*Rhododendron formosum*. Hardy in South-West Ireland.—*Black Hambro*.—*Lonicera tartarica*.—*Mrs. Sartorius*.—1, *Pyrus pinnatifida*; 2, *Cytisus monspessulanus*.—*C. P.*, *Bournemouth*.—1, *Pseudotsuga Douglasii*; 2, *Syringa vulgaris* variety. The other two specimens were too much withered to identify. Both specimens in the second batch are of the Douglas Fir (*Pseudotsuga Douglasii*), though one is apparently from a tree in poor health.—*A. G. G.*.—1, *Crassula* species; 2, *Cuphea miniata*; 3, *Ruellia Portellæ*; 4, *Primula malacoides*; 5, *Chlorophytum elatum variegatum*. The Peach is affected by mildew, due to bad ventilation. Try flowers of sulphur or a solution of potassium sulphide.—*C. H.*, *Worthing*.—1, *Asphodeline lutea*; 2, *Asphodelus albus*; 3, *Camassia esculenta* variety.—*Miss Lloyd*.—*Saxifraga Sibthorpii*.—*H. B.*.—1, 2 and 3, garden seedlings of *Phlox subulata*; 4 and 5, the Irises were beyond recognition; 6, *Fuchsia fulgens*.—*H. A. C.*.—Garden varieties of *Azalea* which have no distinctive names.—*J. M.*.—1, *Crassula lycopodioides*; 2, *Tolmiea Menziesii*; 3, *Pyrus Torminalis*; 4, *P. Aria* variety; 5, *P. intermedia*.

ORCHIDS AT THE CHELSEA SHOW.

THERE were thirteen groups of Orchids, an unlucky number truly, for the magnificent collection of Sir George Holford, which has so often formed a flower show in itself, went unrepresented. The groups stretched the whole length of the north and south sides of the Large Tent. Amateurs were represented by the Duke of Marlborough, Sir Jeremiah Colman and Mr. James Horlick. We saw no epoch-making flower, though there were the usual large number of novelties. The feature of the Orchids was their extremely high general level, and we have no hesitation in saying they have never been bettered at any of the earlier shows.

Messrs. Charlesworth and Co., Hayward's Heath, led off the groups on the northern side of the tent with a design as pleasing in the sustained balance of colour from end to end as in the rich variety and fine culture of the varieties included. The centre-piece was a mass of *Odontiodas* in shades of scarlet, overhung with three white sprays of *Odontoglossum armainvilliers xanthotes*. Two immense pans of *Cattleya Skinneri* on either hand, with their clear shade of purple rose, clashed a little perhaps with the scarlet, but led to lovely masses of *Cattleya* hybrids and *Miltonias* in some particularly good varieties. Hybrid *Odontoglossums* occupied the wings, and these, with intermediate banks of *Lælio-Cattleya Fascinator* on one side and *Lælio-Cattleya Aphrodite* on the other, were linked together at the back by an arrangement of *Miltonias* and *Cattleyas*. This scheme was novel, but impressed us as being a little too flat. The way in which the yellow of *Lælio-Cattleya Euripides* and other hybrids at the base linked up the yellow of the *Oncidiums* overhanging the banks of *Cattleyas* was, however, very pleasing. The group was full of good things. The soft shades of *Thunia Veitchii*, the fine-flowered specimen of *Calanthe veratrifolia*, and such *Odontiodas* as *Charlesworthii*, *Diana*, *Bradshawia* and *Joan* were a few that caught the eye at once.

The Duke of Marlborough, Blenheim (gardener, Mr. G. Hunter), had an interesting collection, but the group lacked a connecting thread which, by connecting allied plants and related colours more closely, would have often added beauty by leading the eye to special points. *Dendrobiums*

nobile virginale and *Deareii* were well flowered, *Cattleya Undine* was another pretty piece of white, and *Brasso-Cattleyas Impératrice de Russie* and *Maronia* were fine plants.

Messrs. J. Cypher and Sons, Cheltenham, had a novel arrangement built up in a square plot from the ground. The four corners were capped with nice plants of *Cocos weddelliana*, while linking two sides was an arch carrying some fine plants of *Dendrobium wardianum*. Under this arch one got the prettiest effects, *Renantheras*, *Cattleyas*, *Epidendrums* and many fine forms of *Lælio* and *Brasso Cattleyas* glinting through films of greenery. There was a lovely piece of Temple's variety of *Cattleya Skinneri*, and *Lælio-Cattleya hyeana* was very fine; but did not those broad-leaved, warm-coloured *Crotons* seem rather too heavy for the delicate white sprays of *Phalænopsis* next them?

Messrs. Sander and Sons, St. Albans, staged a collection on the north tabling which in arrangement and fine quality at once impressed one as one of the perfect things of the show. Twenty-four magnificent *Brasso-Cattleyas* and *Brasso-Lælio-Cattleyas* formed the face of a central trophy, of which the sides showed *Miltonias* in many soft shades. *Trichoplias suavis* and *Hennisii* formed a base, which in a trailing line was continued right and left to the ends of the group. *Phalænopsis* and *Renanthera* were an outstanding combination repeated on each side, and there were grand terminals of *Cattleyas* and *Odontoglossums*. From so many good things it was difficult to select just those few we have space to mention. *Miltonia vexillaria* G. D. Owen, darkly blotched, must be one of them. The white *Cattleyas Mossia* *Wagneri* and *Magali Sander* were very fine indeed. Others were *Cypripedium rothschildianum* The King, *Odontoglossum ardentissimum verulamium*, *Odontioda Roger Sander* and *Miltonia Dreadnought*.

Messrs. Armstrong and Brown, Tunbridge Wells, ended the tabling at the north end of the tent. Here was a regal collection of species and hybrids, regal in name and culture alike, containing such novelties as *Odontioda Coronation*, *Odontoglossum Queen Mary*, *Brasso-Lælio-Cattleya Prince of Wales*, and the old *Dendrobium thrysiflorum* carrying twenty flower-spikes. There was a grand plant of *Cœlogyne pandurata*. *Cymbidium Pauwelsii* was fine. A lovely effect was produced by the slender sprays of *Odontoglossum thompsonianum* leaning through a broad bank of pure white *Phalænopsis*. The real feature of the group, however, was its rich *Brasso* and *Lælio Cattleyas*, which repaid a long examination.

James Horlick, Esq., West Dean Park, Chichester (gardener, Mr. W. H. Smith), sent one of those groups interesting in themselves, and doubly interesting because they were unique. Under a background of Palms was a wonderfully flowered batch of *Vanda teres* arranged in the shape of a crescent on the ground. We really thought them too full of flower, and wished they could have been spread out to cover twice the space. The crescent enclosed a centre-piece of *Calla Pentlandii*, the species with deep green, unmottled leaves and very large, rich golden yellow spathes, which are touched with crimson at the base. Bamboos, *Grevilleas* and Maidenhair Ferns lightened the whole group. An admirable collection.

Messrs. Mansell and Hatcher, Limited, Rawdon, Leeds, were at the south end of the tent, and their group maintained that high standard of artistic staging which they were among the very first to introduce. A bold centre-piece of glistening white *Phalænopsis* was surrounded at a lower level with a belt of the deep red of *Renanthera imschootiana*.

Right in the centre was a glowing carmine piece of *Odontioda Chanticleer*. At either end were masses of *Cattleya Mossia* in many forms, cut off from the centre by recessed batches of *Odontoglossum* hybrids. *Odontoglossum amabile Royal Gem*, *Lælio-Cattleya Eudora* and the yellow of *Odontoglossum crispo-harryanum* were a few of the specially good things.

Messrs. J. and A. McBean, Cooksbridge, showed a batch, in which we found more pleasure in examining individual plants than in admiring the colour scheme as a whole. The arrangement was too "spotty" with the irregular dotting of the *Odontiodas* along the whole frontage. But who cares? Here were *Cattleya Mossia* with twenty-eight flowers, *Oncidioda Cooksonæ* with forty-nine flowers, and grand plants of *Oncidium mcbeanianum* (a new *macranthus* hybrid), *Lælio-Cattleya Helius* (a shade of salmon), *Odontoglossum armainvilliers alba*, *Lælio-Cattleya Anak*, *L.-C. Ganymede* (with yellow wings), *L.-C. callistoglossa ignescens* and, best of all, *Odontioda Perfection*, with flowers of *Chanticleer* colour and *Charlesworthii* size.

Sir Jeremiah Colman, Gatton Park, Reigate (gardener, Mr. J. Collier), sent a beautiful group, of which the first thing to tell was that all the *Odontiodas* (and the group was dominated by them) were Gatton seedlings. One plant carried over two hundred flowers on three spikes, and another over one hundred and seventy. Lady Colman has given her name to specially lovely forms of *O. Bradshawia* and *O. Vuylstekeæ*. Two striking terminals to the group were *Cœlogyne dayana*, the Necklace Orchid, and *Dendrobium acuminatum*, a unique plant which carried five spikes, each with ten to twelve flowers. *Phalænopsis*, *Miltonias* and *Odontoglossums* gave relieving touches of soft colour, and there were many more good Gatton seedlings, but the general scheme of the group was its profuse masses of scarlet *Odontiodas* sprayed out from the slender greenery of *Asparagus albanensis*.

Mr. Harry Dixon, Spencer Park Nursery, Wandsworth Common, had a number of interesting plants. There were several nice forms of *Cattleya Mossia*. *Lælio-Cattleya canhamiana* × *Mendelii* and *Lælio-Cattleya Mendelii* May Queen were both good.

Messrs. Stuart Low and Co., Bush Hill Park, had the largest display on the south side of the tent. The centre-piece was an outstanding trophy of *Phalænopsis*, contrasted with *Odontiodas* and *Renantheras*. The two extremities were solid effective clumps of *Renantheras*, while between were masses of *Cattleyas*, *Lælias* and hybrids broken by little groups of rarities and curiosities. There were *Cyrtopodium punctatissimum*, with curious mottled yellow flowers, overtopped by its enormous horn-like pseudo-bulbs; *Cyrtopodium andersonianum*, with tall spikes of clear yellow; the delightful little blue *Vanda* (*V. cærulescens*), the Bull's-head *Vanda* (*V. cristata*) and strange *Saccolobiums*. The race of yellow *Lælia flava* × *tenebrosa* seedlings also deserved special notice.

Messrs. Flory and Black, Slough, staged a small group in which *Cattleyas*, *Odontoglossums*, *Lælio-Cattleyas* and *Odontiodas* were represented; likewise a pretty mass of the orange *Lælio-Cattleya* G. S. Ball, surrounded by the white of *Phalænopsis*.

Mr. C. F. Waters, Balcombe, Sussex, had a central mass of *Cattleyas* with batches of *Miltonias* on either hand, and the whole was overhung with white *Odontoglossums*. It was a pretty bank of colour, but as one stood back one had a feeling that the arrangement was too flat.

THE GARDEN.

No. 2220.—VOL. LXXVIII.

JUNE 6, 1914.

NOTES OF THE WEEK.

Severe Frosts in May.—In many parts of the country severe frosts were experienced during the nights of the 25th and 26th ult. Mr. Harriss informs us that at Lockinge 8° and 9° respectively were registered on those dates. A great deal of damage has been caused in many places, especially to early Potatoes, French Beans and Roses.

Newly Planted Trees and Shrubs.—Trees and shrubs that were planted last autumn or in the spring should have plenty of water given to them now, for it is just at this time that such plants suffer. Evergreens will greatly benefit by an occasional syringing overhead.

Primula La Lorraine.—This new hybrid, raised by Messrs. Lemoine et Fils of Nancy, promises to be a good garden or cool-house plant. It is a hybrid between *P. Sieboldii* and *P. Veitchii*, and partakes of the characters of both its parents. The flowers are pleasing in colour, and the habit of the plant quite good.

Megaseas as Foliage Plants.—Broad-spreading forms of *Megasea* (*Saxifraga*), with the rich and varied colours of their large leaves, are worth growing for their foliage alone, as when once established they are attractive at all seasons, whether it be on the higher parts of the rock garden, in the wilder parts of the grounds, or by the side of streams, and at the present time are among the most effective of foliage plants.

Planting Annuals.—This work should be finished with as little delay as possible. A showery day ought to be chosen for the purpose, but failing this, the soil should be thoroughly moistened a day previous to planting. Large quantities of the various kinds for cutting can be planted on good, rich soil, so that during the season those plants which are placed in the pleasure grounds may be left uncut.

A Handsome Fumitory.—In *Corydalis nobilis* we have a distinct and extremely attractive plant, and, without doubt, the most desirable of the whole genus. It is of robust habit and perfectly hardy, always yielding an abundance of flowers at this season of the year. They are of a rich golden yellow with chocolate spots on the lip, and are borne on strong stems, leafy to the top, and rarely exceeding 1 foot in height. These rise from a mass of bright green, Fern-like foliage. It is an excellent plant for a damp spot in the rockery,

although it may be planted along the border with equal effect, and can be readily increased by division or raised from seed.

Sowing Mignonette.—Seed may be sown in good rich soil, and a sharp look-out kept for slugs, which are very fond of this plant while in a young state. Soot may be freely sprinkled about the plants to keep slugs in check, and will also prove a valuable stimulant to the plants throughout the season. Several sowings may be

ment can be effected in one season. The grass, of course, will take on a slightly brown tinge, but it soon recovers and comes stronger than ever.

The Bridal Wreath (*Francoa ramosa*).—Plants that are throwing up plenty of flower-spikes should be supported by neat sticks; place them in a cool pit and protect from strong sun. Seeds of this plant may be sown now to produce plants for next season. Sow in pans of fine, sifted soil and cover with sheets of glass. Pot on as soon

as ready, and grow the plants in a well-ventilated pit on a bed of ashes. Protect from sun and never allow them to suffer from want of moisture at the roots.

Cucumbers in Unheated Pits.—Hot-beds may now be made up either in brick pits or in the frame ground, where wood frames may be used. The material should be thoroughly prepared before the bed is made up, and this ought to be trodden tightly together before the box frame is placed in position. The soil should be allowed to become thoroughly warm before the plants are put out, and some covering must be applied at night.

Vases and Boxes.—In the making up of these useful adjuncts to the flower garden it must be remembered that as their season is so very short and the space limited, none but good established plants should be used. Many fine effects can be had by making use of good-sized plants of some of the hardier varieties of Fuchsias as a centre plant, while the rest of the vase or basket could be filled with smaller-growing plants, such as Ivy-leaved Pelargoniums.

Horticulture at the Panama-Pacific Exposition.—Horticulture, we are told, is to be well represented at the Panama-Pacific International Exposition, to be opened at San Francisco on February 20, 1915. A valuable cup is to be offered for the best new seedling Rose that is shown, and many attractions are promised. One of these is a wonderful new Rhubarb,

ANDROSACE PRIMULOIDES AND OTHER CHOICE ALPINES ON A DRY WALL IN A DEVONSHIRE GARDEN. (See next page.)

made from now until the end of June on rich soil which has been made firm by treading.

To Eradicate Daisies on Lawns.—Where Daisies are present to any extent they very soon crowd out the finer grasses, and means should be taken to at least check them. For this purpose there is nothing better than finely powdered sulphate of ammonia applied in dry weather at the rate of 1oz. to every square yard. This must be repeated from time to time, and if this is persisted in, it is really surprising what an improve-

ment we are informed, is "extraordinary for its exceptional length of stem, which is 2 feet to 3 feet long." No doubt many of our readers will journey to San Francisco purposely to see such wonderful Rhubarb—unless, as is quite likely, they happen to have some with longer stems at home. A new Sweet Pea, which is not an annual, but a perennial, is to be another feature. The flowers of this, we are solemnly told, will "no more fade than will the green of living Ivy," and blooms will remain fresh till the end of the year.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Androsace primuloides in a Dry Wall.—I am sending you a photograph of *Androsace primuloides*. The plants are growing in a dry wall facing south, and were very small in $2\frac{1}{2}$ -inch pots when they were planted in October, 1912. Now they are two fine clumps a foot or more across, and a mass of bloom. In dry walls we can grow *Androsaces* here without any trouble or covering with sheets of glass in the winter, as the drainage is perfect and they get every bit of sun. In the same photograph will be seen a clump of *Saxifraga pyramidalis*, also *Sedum pilosum* and *Campanula carpatia*. The last two have flowered since the photograph was taken. The *Androsaces* are growing in garden loam mixed with sea-sand and small

in the sunny South and West, where the bushes give the most satisfaction in this country. Layering is the most ready means of propagation.—A. O.

Cinerarias from Cuttings.—*Cinerarias* are so universally grown from seeds that the fact that they can be readily increased by means of cuttings is not generally recognised. Such, however, is the case; in fact, there are a few hybrids that do not produce good seed, and therefore can only be propagated from cuttings. Again, even among the florists' forms it may be desired to increase a few of marked beauty or possessing some features that cannot be depended upon to come true from seed. To ensure cuttings, the old plants should be shortened back after flowering, when young shoots will be pushed out from the base. As soon as these are about two inches in length they may be taken as cuttings, and if inserted into pots of sandy soil and placed in a close propagating-case in gentle heat they will soon root.—H. P.

A SPRAY OF CORNUS NUTTALLII WITH LARGE CREAMY WHITE FLOWERS.

stones.—E. A. FROUDE, *Kingsbridge, South Devon*.

A Beautiful Cornel or Dogwood: *Cornus Nuttallii*.—This Dogwood, which is a native of Western North America, is the most attractive species of the genus from a floral standpoint. Strictly, however, the attraction lies in the showy bracts, four to six in number, surrounding the closely packed head of flowers. These bracts are creamy white, 1 inch to 3 inches long, forming the so-called flower, which may be 4 inches or even more in diameter. *Cornus Nuttallii* is a deciduous tree up to 50 feet to 60 feet, occasionally more, in height, in Western North America. As grown in this country it is usually a bush or small bushy tree. The flowers are formed at the tips of the young shoots in autumn, gradually developing during the winter and expanding in the spring. Flowering early, the bracts and flowers are often damaged or crippled by frosts and cold winds. It is thus very desirable to plant Nuttall's Cornel in a sheltered spot, except

Primulas Causing Rash.—I see in the issue of THE GARDEN for May 16 "J. D.'s" remarks re *Primulas obconica* and *malacoides* causing a rash. Both these valuable decorative plants cause the same rash on myself, and at one time I was about to get rid of them when it occurred to me to try an ointment that I always keep by me for bruises. The rash always comes out on myself within half an hour from the time of handling the plants, so the next time I felt it coming I smeared my hands and arms over with the ointment, and was delighted to find it took away all irritation almost immediately. I should not like to say that it would cure everyone in the same way; but I think anyone who is fond of these plants and is afraid to grow them on that account would do well to try the ointment. I do not wait for the rash to come out now, but directly I have finished handling the plants I treat my hands. The name of the ointment is "Healo," made by Mr. Maurice Smith, chemist, Kidderminster. Should any of your readers try the remedy, I should like to hear

the result. I might add I hold no brief for Mr. Maurice Smith.—C. H. CLARKE, *The Garden, The Heath, Bewdley, Worcestershire*.

Primula pulverulenta Mrs Berkeley Producing Seed.—In the course of recent visits to the garden at Clandon Park, Surrey, and to the nurseries of Messrs. R. Wallace and Co., Colchester, I have seen this charming *Primula* seeding with as much freedom as, or even greater than, the species. The point is of interest, as Dr. Macwatt has repeatedly stated in the columns of THE GARDEN that this variety is sterile. It was pointed out to me at Colchester that both pin-eyed and thrum-eyed plants are in existence there. It is just a suggestion, but possibly the cross-fertilisation of the two forms is necessary in order to yield fertile seed. In any case, the fact that both forms exist is proof that there are two stocks of this variety, for either form would continue to reproduce the same kind of flower so long as it was propagated vegetatively. With *Primulas*, at least, it is not safe to generalise regarding their sterility. Thus, it was not many years ago that *P. kewensis* was described as a mule hybrid, i.e., one not capable of producing fertile seed. We now know that this hybrid produces seed with remarkable freedom.—C. Q.

A Good Red-Flowered Saxifrage.—Probably the best red Mossy Saxifrage which has come under our notice is the fine variety *Beacon*, which was raised here a season or two ago. In size the flowers are fully equal to *bathoniensis*, but the colouring is much deeper, reminding one of the brilliant depth of crimson which we get in the small-flowered *Guildford Seedling*. The stems are stiff, the blossoms held erect, and the habit of growth is distinctly good. In our opinion it is even better than our own *Fire King*, which is now in the hands of Messrs. Piper of Bayswater. Last season we formed the opinion that *Fire King* was even better than *sanguinea superba*, and if our opinion is correct, then it emphasises still further the value of *Beacon*. The whole race of Mossy Saxifrages seem productive of too many varieties, but it is well to record the appearance of any that are especially noteworthy.—P. S. HAYWARD, *Clacton-on-Sea*.

***Tricuspidaria dependens* in South-West Scotland.**—Probably the finest plant of the wonderfully beautiful *Tricuspidaria dependens*, still frequently known as *Crinodendron Hookeri*, in Scotland is that in the rock garden of Mr. W. D. Robinson-Douglas of Orchardton in Kirkcudbrightshire. It has been at Orchardton for a considerable number of years, and has stood the tests of several severe winters. None, however, proved so injurious to this fine shrub as that of 1912-13, when a wet autumn, so mild that Roses were cut the day before the severe frost came in the same garden, was followed by a sudden and very severe spell of hard weather. The temperature went down to about zero—an unusual thing in this garden close to the Solway—and remained very low for some days. In the spring *T. dependens* was a sorry spectacle, and there were but few green leaves left on it. During last summer it made a wonderful recovery, and although slightly less in stature, it now shows hardly any traces of its ordeal. At the time of writing it is laden with hundreds of flower-buds, and in a short time will be a very beautiful spectacle. It is planted on a slightly elevated mound in the rock garden and facing south; it is some 8 feet or 9 feet high, and on its mound rises well above the spectator.—S. ARNOTT.

The Asarabacca Plant.—This plant is, I fear, known to very few. I have visited a good many gardens in the United Kingdom, but it was only four summers ago that I stumbled upon it in the old garden at Midmar Castle, Aberdeenshire, and I would have been unable to identify it had I not had for a companion the local doctor, who is a good botanist. The botanical name of the plant is *Asarum europæum*. Its dull brown flowers are not very attractive, but its Cyclamen-like leaves, growing in pairs, are very ornamental. It is worthy of a place at the foot of the rockwork or in a shady border; or, better still, it may be employed as an edging under the shade of trees, as I saw it at Midmar Castle.—CHARLES COMFORT.

A Good Forget-Me-Not.—About twelve months ago an article appeared in THE GARDEN from the pen of Mr. C. Blair of Linlithgow, in which he enumerated some good things worth growing—I think that was his phrasing. Among the plants mentioned was a *Myosotis* named Barr's Alpine Blue, which the writer strongly recommended, and which we at once obtained. For some time past and at present we are verifying the excellent account Mr. Blair gave of this variety. The colour is a most attractive shade of blue, much resembling *M. rupicola*, which variety one might imagine entered into the parentage of the above. Compared with Barr's Alpine Blue, several varieties now catalogued are not worth growing.—C. T., Highgate.

The Ginger Plant for Decoration.—It is from the rhizomes of this East Indian plant, *Zingiber officinale*, that we get our supplies of ginger, and on that account it is of great commercial value. I would like, however, to draw attention to it as a decorative plant, especially for the house. A well-grown plant with its Canna-like foliage, which stands the wear and tear of house decoration, is an object not to be despised. Its leaves are also highly aromatic, and are to me always more suggestive of cinnamon than of ginger. If an old plant is broken up in the spring and nice pieces are potted up into 6-inch pots, they soon make fine decorative plants if grown in a stove temperature. They should be grown in a light, rich soil, in which the rhizomes run freely.—C. C.

Too-much-alike Auriculas.—Your correspondent "Taplow," on page 239, opens up a subject which I am afraid cannot be answered briefly. He mentions that few of the varieties of Auriculas named in trade growers' lists are entered for competition, and if he excludes those that are relatively high priced, he still further reduces the number. This is, as applied to the alpine section, mainly caused by the fact that many varieties which were exhibited ten or fifteen years ago have been superseded by more recent introductions of greater merit, and not, as in the case of Sweet Peas, because they are too much alike. There are cases where Auriculas are so much alike as to be hardly distinguishable, but these cases are not many. Mrs. H. Turner and Defiance are much alike, and though once in the front rank, are rarely seen now. Among more recent and meritorious varieties may be mentioned Exquisite and Unexpected, or Miss Violet Vanbrugh and Muriel; but this does not in any way prevent them being exhibited. In the slow growth and increase of the plant will, I think, be found the reason why the bulk of the catalogued varieties of alpine Auriculas are not seen on the exhibition table. Many of the best exhibition varieties at the present time have been raised by amateur growers, and are

exhibited by them. In some cases these raisers will not part with plants, and they certainly are not tempted to dispose of their best productions until they have materially increased their stock. When they do part with plants, it is usually among their friends and members of their respective societies, by whom they are for some time shown before they find their way into trade lists. Argus and Thetis, two good exhibition varieties, were a long time before they found their way into a dealer's list, although they had been shown for many years at the National Auricula Society's (Midland Section) shows. By the time many of the varieties have increased sufficiently to sell at a cheap rate, other varieties are raised which supersede them on the exhibition table; at least this is so as regards the alpines. Among the show Auriculas there are many of the more moderate priced which are still of great value for exhibition, although the two best grey edges, George Lightbody and Richard Headley, still command a fairly high price, in spite of their

MR. E. HARRISS, HEAD-GARDENER AT LOCKINGE.

sixty years, due to slow growth and increase coupled with a large demand. A dozen good alpines taken from trade growers' lists, excluding new and expensive varieties, would be Argus, Duke of York, Janet, Miss Berkeley, Ettrick, Mrs. James Douglas, Phyllis Douglas, Charmer, Majestic, Mrs. Martin Smith, William Smith and Ilene. I would suggest that your correspondent joins one of the sections of the National Auricula Society and gets into touch with growers who hold stocks of good things not catalogued. I have forwarded the report of the National Auricula Society (Midland Section) for the last three years for your correspondent's perusal.—G. J. S. [Will "Taplow" please send us his name and address, which we have mislaid, so that we can forward the report?—ED.]

FORTHCOMING EVENTS.

June 10.—Conference on Hardy Plants at the Anglo-American Exhibition at Shepherd's Bush. (Provisional.)

PLANNING AND PLANTING THE LITTLE GARDEN.

WE are pleased to state that our competition for planning and planting the little garden is creating a great deal of interest. For the benefit of new readers we may state that we are offering cash prizes to the total value of £33 12s., as well as a number of book prizes, for the best designs for planning and planting the little garden. Full particulars of the competition were published in our issue for May 18, and a copy of the rules and conditions will be forwarded to anyone on receipt of 1½d. in stamps. The application coupon for the outline plans will be found on page iv. of this issue. All questions relating to the competition will be fully answered in our issue for June 20, and not in the present issue, as erroneously stated last week.

Important.—Some correspondents are evidently under the impression that they cannot enter the competition after June 6. They can do so as late as they wish. The only fixed date is September 1, 1914, for the delivery of the completed designs.

TWO INTERESTING VIOLAS.

Viola Red Dawn.—With our extensive culture of *Viola gracilis* hybrids it is not exceptional for a new and noteworthy variety to arise from among its fellows. The form under notice is one of the best of the present year, and offers a pleasing contrast in colour to the majority of existing varieties. The colour is a pleasing rich rosy red, and the flowers are rounded in formation and held erect upon stiff stems. The growth is very dwarf, the tufts of foliage keeping to the ground-level, and the leaves are less smooth and more rounded than in most *gracilis* varieties. If, like its better-known predecessors, it retains the same ability to withstand drought, then Red Dawn will assuredly be in the front rank of rock garden Violas. To those of my readers who know the fine yellow variety Golden Wave, I may say that Red Dawn is almost identical in every way, except in its attractive colouring.

V. gracilis Golden Gondolier.—One of the most striking hybrids of the *V. gracilis* section we have yet raised is the variety provisionally named Golden Gondolier. It possesses the same close, dwarf habit as the cream and yellow variety Gondolier (which with its hordes of blossoms neatly set above the low foliage streaming through a big drift between the rocks makes one of the grandest drifts of blossom in the whole rock garden), which is notable for its big drifts of blossom. Golden Gondolier is very floriferous, with small, ovate leaves produced in tufts against the ground. It is far neater than *gracilis* itself, and, like the other mountain Violas, can withstand drought and flourish in poor soils. The colour is a lovely clear golden yellow, without any ray markings or other colourings to mar its shining beauty. As a subject for rock massing it will prove very attractive, and will be an even more valuable plant than Golden Fleece, Golden Wave or aurea (previous *gracilis* forms), all of which were raised here.

(Clacton-on-Sea,

P. S. HAYWARD.)

GARDENS OF TO-DAY.

LOCKINGE.

CHARMINGLY situated in a well-wooded vale of the Berkshire Downs, the gardens at Lockinge, the country seat of Lady Wantage, have for many years been famed throughout the United Kingdom not only for the wonderful examples of fruit that are annually grown there, but also for the charming flower-beds and natural glades that are to be found running parallel to the mansion. This fame is due in no little measure to the skill of the late Mr. Fyfe, who was gardener there for many years.

It was our good fortune, during the opening days of May, to spend a particularly pleasant week-end with the head-gardener, Mr. E. Harriss, and through the kindness of Lady Wantage we are able to reproduce herewith photographs showing a few of the many charming features. The site at Lockinge must have been ordained by Nature to become a garden. Starting at the east end of the pleasure grounds is a vigorous spring of clear, sparkling water, which wends its way now through wooded glades and anon over rocky beds, right past the mansion, losing itself in a large ornamental lake, on the surface of which coots, wild duck and swans disport themselves. It was a great pleasure to find this natural source of beauty unspoiled by artificial attempts at embellishment. At various places along the stream-side suitable shrubs, such as Japanese Maples, hardy Bamboos, *Cytisus præcox* and *Cotoneasters*, have been planted to form more or less conspicuous features in the landscape, yet with such good taste as to render them parts of the scenery itself, instead of, as is too often the case, being glaring examples of misplaced energy. The same may be said of the herbaceous plants that find a happy home either in moist beds by the streamside or among the noble rocks that overhang the banks at the steepest parts. In the beds we found such simple yet delightful plants as Primroses, Forget-me-nots, Arabis, Aubrietias, May-flowering Tulips and hosts of others, all planted with judicious care so as to harmonise with their surroundings.

On a rather steep plateau, overlooking the stream at its widest part and commanding a fine view under the noble Elms and Beeches that stand as sentinels over Lockinge, is the wild garden, which at the time of our visit was rendered beautiful by the latest of the Daffodils and the earliest of the May-flowering Tulips. These are all planted in grass, and it was interesting to note that some of the Tulips, notably *Pride of Haarlem*, were at least as vigorous as the first year after planting, while others showed that they would need replenishing. It would therefore seem that it is not an impossible task to naturalise Tulips in

grass, providing the proper varieties are chosen. Along the northern front of the mansion we were particularly charmed with a narrow border filled with splendidly cultivated Wallflowers of several colours. At one end these were partly overhung by a magnificent bush of *Berberis stenophylla*, while near by, in a nook formed by evergreen shrubs, were two beautiful examples of *Pyrus floribunda*, a Japanese Apple that ought to be much more extensively cultivated where flowering shrubs or trees are appreciated.

On the south side we found a charming little grey stone church nestling close to the mansion, its twin gables and solid square tower forming a delightful feature in the landscape. The formal beds that are situated here were, at the time

VIEW IN THE ROCK GARDEN AT LOCKINGE. TO THE RIGHT OF THIS IS A DELIGHTFUL STREAM OF WATER.

of our visit, resplendent with Wallflowers, Violas, Forget-me-nots, Tulips and other spring flowers, the whole being so arranged as to give a pleasing and harmonious effect.

Specimen plants in tubs are a great feature at Lockinge during the summer months, and although we were too early to see these in their flowering positions, we found them in the plant houses undergoing their final hardening. *Agapanthus*, *Fuchsias* and that beautiful scented-leaved and rose-pink flowered *Pelargonium Clorinda* were a few among many that are utilised for this purpose. In the open were some remarkably fine plants of *Rose Dorothy Perkins* in tubs, the healthy appearance of the *Roses* auguring well for a glorious display of pink festoons later on.

While writing of *Roses* we must not forget the most charming of all, and one for which Lockinge is justly famed. We refer to *Fortune's Yellow*, a *Rose* that many find difficult to cultivate, and the flowers of which are a glorious mixture of rose pink and old gold. There are two wonderful plants in these gardens. One, in the conservatory, has an enormous stem and scrambles in a delightfully free and easy manner over the iron rafters of the building, where, at a height of 20 feet or more it makes wonderful garlands with its exquisite fragrant flowers. The other plant is in the corridor of the fruit houses in the kitchen garden. Although scarcely so large as that in the conservatory, it flowers more freely, and we shall ever remember the glorious sight that it presented. Truly it is

a wonderful *Rose*—when grown as they grow it at Lockinge. In the plant houses we were pleased to find some beautiful *Clarkias* in pots, large colonies of *Gloxinias*, *Coleuses*, *Lilies*, *Orchids* of many kinds, *Schizanthuses*, a very fine lot of *Malmaison* and *Perpetual-flowering Carnations*, and a great many other plants too numerous to mention in the space at our disposal.

Leaving the pleasure grounds and plant houses, we must give a passing note to the kitchen garden, in which, of course, the fruit houses are situated. It is, perhaps, in this department more than in any other that Mr. Harriss excels. Here, on May 1, were *Black Hamburg Grapes* ready to cut, and fine bunches at that. We should say that some of them—indeed, a good many—would have turned the scale at 3lb. a bunch, and we have seen much worse examples displayed at July and August shows. *Foster's Seedling* and *Buckland's Sweetwater* were also nearly ready for cutting, while later houses contained some very fine *Muscats*, which had set particularly well and which had just undergone their final thinning. *Peaches* and *Nectarines* in pots, as well as the usual trees in borders, were all in excellent condition, but perhaps, next to the *Grapes*, the *Strawberries* were the most interesting. We do not remember seeing a better lot anywhere; seldom have we found as good. The

variety used mostly is *Royal Sovereign*, and there is no doubt that for all-round purposes it is the *Strawberry* to grow. *Figs* that were just ripening were also excellent, one fine old tree of *Brown Turkey* carrying a really wonderful crop. *Melon Hero* of Lockinge, *French Beans*, *Peas* ready for gathering, and new *Potatoes* of good size and quality were a few of the many other interesting features that occupied our attention here. During the past year substantial, roomy and convenient new bothies have been erected for the journeymen gardeners, an item that will be of interest to the many who have spent the early days of their gardening careers at Lockinge, about the gardens of which volumes might be written had we the space to devote to it.

RHODODENDRON INTRICATUM

A New Dwarf Species for the Rock Garden.

Hudson & Keenan, Ltd., Printers, London, S.W.

COTTAGE TULIPS.

DARWIN Tulips can be defined with very fair accuracy. Their stems are tall and strong. The lower portion of the flower is rectangular in outline. The petals possess considerable substance, and are coloured with some shade of purple, mauve, red, or pink. But in a few cases they are so dark as to be nearly black, and so light as to be practically white. Their bases are black, blue, or white, or some combination of the same, but never yellow. Something like the above will, I think, be found to be the definition of a Darwin in the Tulip list which the Royal Horticultural Society is proposing to publish before long. All other late-flowering varieties, with the exception of the Parrots, which have lacinated petals, and the species, which are the wildings of Nature, are *ipso facto* Cottage. Hence the section includes all yellow-based flowers, such as Clio or Golden Bronze; all such dwarf ones as Glare of the Garden and Golden Crown; all pointed-petalled and elegantly shaped beauties such as Mrs. Moon and La Merveille; all slender, wiry-stemmed forms, such as Picotee, Mrs. W. O. Wolseley and retroflexa; all old-fashioned striped blooms like Chameleon, Columbus or Zomerschoon; all breeder types of other strains, such as Inglescombe Pink or Prince of Orange. Undoubtedly there are some, especially among those that fall under the last heading, that so very nearly resemble a true Darwin that the non-Tulip person will be perplexed, and I am afraid it must be so until a sort of instinctive knowledge is acquired which somehow or other tells us at a glance in which category a doubtful one should be placed.

It is a matter of history that the introduction of the wonderful Darwin strain by Messrs. E. H. Krelage and Son of Haarlem almost a quarter of a century ago did more than all else to bring the Tulip race to the prominent position in horticulture which it holds to-day. Not right away, all at once, for many of the early introductions were poor and small, and did not appeal to flower-lovers as the later and better kinds did, but it was a beginning. Cottage varieties were in the same position to some extent. Many of the best and most beautiful either had not been found or were only existing in such small quantities that neither Barr nor Hartland could put them into commerce. But they never "hit" people all at once on first sight as the Darwins did, and as they still do, and yet they have many devotees. "I am so fond of the pointed ones" is often said to me as a visitor will stop before a bed of the rich deep crimson Mrs. W. O. Wolseley or the pale warm cherry-coloured Prince Charming or the taller and more orange shaded La Merveille.

"I do like these for my rooms" a lady will say as she stands before a mass of Picotee or retroflexa, "they are not so stiff to arrange as those

strong-stemmed ones." These two remarks give two great reasons why we cannot do without the Cottage type. We must have change. It is a law of life. The flower specialist gets it in minute differences, the all-round person in broader diversities, such as that between pointed and round petals, bright and paler coloured blooms, taller and shorter height of stem. Hence Cottages are foils to the Darwins. Again, for decoration in vases the more graceful varieties must always hold their own wherever they can be *home grown*, for I freely allow that many of the prettiest and most graceful are not such travellers as Clara Butt or Mr. Farncombe Sanders, and can never be *market* flowers, as they are. These we must grow ourselves, and if we can only give them a bed or two in the kitchen garden, we may always have them, once we have purchased the bulbs, provided we look after them. I am, however, forgetting that my original intention was to

because of its height and size is a conspicuous feature. Many have said it is their favourite of the yellows. On a dull day I suppose the Tulip of all others that is most frequently selected as the one sort that "*I must have*" is the charming warm buff pink Mrs. Kerrell. It is exceedingly lovely, not only in colour, but in shape. Inglescombe Pink is a Tulip of much the same shade. This year it has been more taking even than usual, as the pink tone has persisted for a long period. It is a fairly tall grower with a conventional flower. Orange King, which has very straight-looking petals, is a beautiful orange with a pink or rose flush all over them. It is a singularly effective bloom, and although there was not a very large patch of it, it usually caught people's eyes. Now that it can be had at about 2s. to 2s. 6d. per dozen, it ought to be more used than it was in its dearer days. Salaman, a tall, Darwin-like plant, with fine silvery mauve blooms, was

FORMAL FLOWER-BEDS ALONG THE SOUTH FRONT OF LOCKINGE.

describe some of my garden favourites of the present year. A good deal depends on the weather. If the day is bright and sunny, Louis XIV. is almost invariably singled out with very often a remark like this: "What a lovely dress those colours would make!" The deep rich purple, with the rich brown edging of the petals, is very fine indeed. The large tortoiseshell comb coloured Gondvink and the rich amber Golden Bronze (syn. Toison d'Or) are always good in bright light, and are seldom passed by unnoticed. For a long time I have in my own mind coupled these together with the beautiful nicely baked biscuit brown Clio as the best of all the brown-yellow shades; now, however, I must add Prince Albert, a sort of pointed Gondvink, and Coridion (not, please remember, the Darwin Corydon—the names are sometimes muddled), which has a warm rosy grey petal with a broad edge of buff, and which

to be found in three places. It was greatly admired. I myself am inclined to put it at the head of all of this tone of colour, be they Darwins or Cottage. The brilliant scarlet Marksman and the rather dull orange red Fairy or Panorama both had many admirers, and can be confidently recommended as *At* garden plants. Of the striped kinds, Chameleon is the one most frequently picked out. Unfortunately, it is a very slow increaser, and its curious but attractive heliotrope, maroon and yellow colouring will never be very common in gardens.

I am glad to say that there are plenty of low-priced varieties that can quite hold their own with those more expensive ones which I have already alluded to. Such are Isabella (no end of people asked its name), Picotee, Golden Crown (an immense favourite), La Merveille, Inglescombe Pink, gesneriana lutea, Fairy Queen,

CYRTISUS PRÆCOX AND JUNIPERS EFFECTIVELY GROUPED WHERE THE STREAM ENTERS THE LAKE.

gesneriana spathulata, Didieri alba and Primrose Beauty, each of them good and to be found in the usual lists.

JOSEPH JACOB.

SEASONABLE NOTES ON AURICULAS.

ANY plants that were not repotted last month must now be given attention, as it is advisable for all such work to be accomplished by the end of June, excepting, of course, those plants that may have been selected for bearing seed. These ought never to suffer for lack of moisture at the roots, or the seed will not be of good quality and germination will be slow. The hot months of the year are somewhat trying for Auriculas, and wherever possible a cool position should be chosen. If ordinary wooden frames which can be easily moved about are employed, no difficulty will be experienced in finding a congenial spot. In most gardens there is generally a north wall sufficiently high to protect the plants from strong sunlight, and such a position is ideal for Auriculas throughout the summer months.

General Treatment.—The plants that were potted first are now beginning to root nicely, and may receive water at more frequent intervals; but till they reach that stage only enough should be given to maintain the foliage in a rigid condition. They will, in all probability, lose a few of the lower leaves, which must be removed directly they will part easily from the stem, and the same remark applies to the old flower-stalks, which will soon begin to turn yellow and gradually wither up. The collection ought to be gone over occasionally and the plants carefully examined,

especially during the period in which the old flower-spikes are being picked out, as it sometimes happens that water accumulates at the base and causes the rot to set in. If this is noticed in the early stages, and a little powdered charcoal or sulphur is applied at once, no harm will accrue. In growing Auriculas I always arrange the alpines in one frame and the show varieties in another, because during the summer and autumn months the lights are removed as much as possible, both day and night. I never mind the alpines getting a few showers of rain on them, but with the show kinds it is not advisable, on account of many of them being covered with farina; hence the advantage of providing them with separate frames.

Cleanliness.—One of the most important factors in Auricula culture is cleanliness, and directly any green fly is seen, the frames should be vaporised without further delay; while an occasional fumigation will kill all the woolly aphids that may be clustering around the necks of the plants. Another most destructive pest is the caterpillar, a similar insect to that we meet with on the Cabbage tribe. It is only troublesome at this time of the year, and is usually found underneath the leaves. If the attack is a mild one, the insects may be picked off; but should they be at all numerous, fumigation is the only effectual remedy. They must be exterminated at once, or the plants will be rendered unsightly for several months.

Additions to the Collection.—No doubt the enthusiast has paid a visit to one of the Auricula shows and noted any that took his fancy; but the following are desirable sorts, and are worthy of a place in any collection: Alpines—Admiration, Majestic, Dazzle, Ettrick, Golden Dustman, Miss Berkeley and Edith Winn. Show—Daffodil, Harrison Weir Bellona, Marmion, Prince Charming and Rifleman.

T. W. BRISCOE.

COLOURED PLATE.

PLATE 1495.

A NEW DWARF RHODODENDRON.

R. INTRICATUM.

THE accompanying coloured plate depicts one of the most distinct of the new Rhododendrons introduced by Mr. E. H. Wilson from China.

Messrs. James Veitch received seeds from him in 1904, and three years later—on April 2, 1907—the Royal Horticultural Society gave the plant a first-class certificate under the name of *R. nigro-punctatum*. From the true *R. nigro-punctatum* the subject of the coloured plate is readily distinguished by the short stamens; and while *R. intricatum* is in full flower at the end of March and early in April, *R. nigro-punctatum* flowers in May, and has fewer flowers in a truss.

R. intricatum is a dwarf alpine shrub common in the Tachien-lu district of Western Szechuen at 11,000 feet to 15,000 feet elevation, where the plants attain a height of 2 feet to 3 feet. Comparatively slow in growth and forming neat little

compact evergreen bushes, this is one of the best, if not the best of all the dwarf-growing Rhododendrons for the rockery and alpine garden. The small, oval leaves are a quarter of an inch to two-thirds of an inch long, and half as wide, dark green above, white beneath, freely clothed on both surfaces with shining brown scales. The flowers are in terminal clusters of three to six blooms, about half an inch across, and very freely produced. Lavender blue will perhaps best describe the dainty shade of colour. When in flower the neat little bushes are very attractive, almost suggestive of a bunch of Violets in the distance. At Kew this year several very beautiful plants were to be seen effectively grouped near King William's Temple, and these were a source of great interest to visitors.

Seeds and cuttings provide ready means of increase. The best time to insert the cuttings is in late summer, when the young shoots are partially mature. Use sandy peat and plunge the pots in a propagating-frame with slight bottom-heat. The tiny plants commence to flower when only a few inches in height. Their rate of growth is comparatively slow. Plants seven years old from cuttings, though forming freely branched bushes, are not yet a foot in height.

R. fastigiatum is a closely allied species, also from China, recently introduced by Mr. G. Forrest. The flowers are similar in colour to *R. intricatum*, but it has distinct protruding stamens, flowers a month later, and the leaves are ovate-lanceolate. This must be one of the quickest Rhododendrons to flower from seeds, plants from a sowing in the spring of 1911 flowering fifteen or sixteen months later in the autumn of 1912. A plant exhibited by Mr. G. Reuthe, Keston, Kent, received an award of merit from the Royal Horticultural Society on April 7 this year. The average height of mature plants is said to be from 1 foot to 2 feet.

FURTHER NOTES ON PEAT "ROCK GARDENS."

IN fulfilment of the promise I gave in my article upon peat "rockworks" which appeared in THE GARDEN of April 18 last, I now give a list of plants tried, or upon trial, in them; but before doing so I should like to deal with such queries of general interest as have been put to me by readers of THE GARDEN.

By the "top spit" of the bog I meant that portion of the top of the bog upon which the Heather grows. This, when dug out with a sharp spade and the Heather or other growth trimmed off, not only looks much better than the slabs of peat cut from the interior of the bog, but also retains its shape. The soft slabs of peat are liable to crack in dry weather and to wear away with continual rain, whereas the roots of the Heather in the "top spit" hold it together and prevent cracking and wearing.

"Loose peat" is the litter—from dust to lumps the size of one's fist—which is found in and around where peat is cut for fuel, and the more fibrous it is the better. The use of dried peat (which one obtains for stable litter) has been suggested to me, but I would not advise it. It is very dry and hard. As regards the question of peat obtained from limestone districts, I do not think that traces of lime in the peat are a serious drawback. Although Azaleas may not like peat from a limestone district, I find that the majority of alpine plants are not so particular in this respect. I have *Campanula alpestris* (*C. Allionii*) and other "lime haters" quite happy in limestone moraines.

As to the proportions of the mixtures in the special pockets, I do not think one can lay down a hard-and-fast rule. It is a matter for one's own judgment, influenced to a certain extent by a few general principles: (1) Plants of naturally strong growth, such as *Campanulas*, will not need any addition to the peat soil. (2) Plants of slow growth and those requiring light soil in shade like an addition of leaf-mould. (3) Heat-lovers should have a little leaf-mould and a good deal of sand. (4) *Primulas* and moisture-lovers like an addition of loam, and prefer the loose peat to be not too fine. They especially like to root into good-sized lumps of peat as big as one's fist. I have a level bed in almost full sun in which *Primula pulverulenta*, *P. Munroi*, *P. Unique*, &c., live quite comfortably squatting upon lumps of peat without artificial watering. (5) *Haberleas*, *Ramondias* and such plants seem to prefer the cracks and joins between the solid peat blocks, and, when once established in them, will bear an amount of sun that would surprise anyone who hitherto has confined them to the shadiest rocks. I am under the impression that *Ramondias* flower much better if they are so placed that they can get a little sun without undue scorching. They certainly flower much earlier, and by varying their situation one can prolong their period of flowering.

As regards the "slopes" and "pockets," these on the sunny side should be almost level if they are to retain moisture in the summer, while upon the shady sides the fall should be sharp to enable the excessive winter rains to run off. It is an advantage to build your peatwork as soon as possible after the receipt of the large blocks from the bog. They are then fresh and moist, and if, as they are built up, their edges are carefully pressed together and any cracks packed tightly with soft peat of the consistency of cream cheese, the blocks will almost invariably knit together, and the whole cliff will assume the appearance of a solid block.

A correspondent suggests utilising peat blocks cut for fuel, but these have obvious disadvantages. They are small (the blocks should be about a yard square), dry and non-fibrous, and I should think much more expensive to buy.

I have received numerous queries as to cost, but these I find the most difficult to answer. As a rule, there is not much difficulty in obtaining the top spit and the refuse loose peat from bogs cut for fuel. Both are practically useless to the fuel cutter, and can be obtained for very little beyond the price of cartage. This, of course, varies with the locality; but in any case the price of the cartage must compare very favourably with that of soil or stones. The peat is so light that horses can pull a load of peat blocks which would cover a space three or four times larger than any load of rocks they could draw.

The following list includes all plants put on the peatworks up to the present planting season. Where no letters are added, they are growing in pure peat. Where they are growing in mixtures, the letters S, L and M have been added to indicate that either sand, leaf-mould or mould (loam) has been mixed with the peat. In addition, it must be understood that plants liking sun and also moisture (such as *Gentiana verna* and

Ranunculi) have stone chips—a few round the roots and others scattered upon the surface—to prevent too rapid evaporation.

GOLD MEDAL ROSES.

HAVING met with many disappointments after a full and fair trial, I have looked up the list of new Roses that gained the gold medal of the National Rose Society since that honour was offered. It is recognised, both at home and abroad, that no other award surpasses, or even equals, this; and yet I find no fewer than fifteen winning varieties that are not even mentioned in the last extensive list of Roses issued by the National Rose Society! Up to 1908 they have discarded from the most extensive list published in Great Britain no fewer than fifteen of our premier gold medal Roses, and I venture to assert that some of the fifty-two gold medal holders that have won since that time will before long join the great majority, so far as general culture is concerned.

The following are the fifteen not included in the official list of the National Rose Society; but I must honestly say a few of them are really good, if not sufficiently so to have satisfied the large catalogue committee: Sir Rowland Hill, Salamander, Ulster, Marchioness of Dufferin, Marchioness of Downshire, Marchioness of Londonderry, Purity, Mrs. James Cocker, Sunrise, Alice Lindsell, Ben Cant, Duchess of Portland, Queen Alexandra, Edith D'ombrain and Mrs. Campbell Hall.

Many that are still retained in the official catalogue are of very little use, except to provide an occasional bloom for the exhibitor. I doubt even if Edith D'ombrain exists, except in two or three gardens besides that of the raiser or introducer. No one else catalogues it so far as I can discover. Then we have such virulent mildew breeders as Mildred Grant, Queen of Spain, Bessie Brown, His Majesty and Her Majesty among the gold medal holders, six of the very worst as regards that disease.

There are many winners of silver-gilt medals and cards of commendation at the meetings of our very deserving society (for which I have the greatest respect) that are not catalogued and are but little grown.

What am I driving at? Well, let us be more careful, and if not possessed of plenty of money, time and ground, confine ourselves more to the numerous well-tried and proved Roses that are better worth the high prices asked, and which we can obtain at cheaper rates. Some of the new and lauded improvements are priced at 10s. 6d., 7s. 6d. and 5s., while one was sent out at 21s. a plant. Upon most occasions, too, these are by no means strong or vigorous plants, and take some time to become established. Good ground plants of the finest varieties can be obtained at 9d. and 1s. each now, and I am only warning beginners against the folly of imagining they have something so superbly better in our newer Roses, while at the same time admitting that many of them are real gems that have certainly come to stay. Let us wait and see. We are not hard driven for good Roses.

MURRAY HORNIBROOK.

Knapton, Abbey Leix, Ireland.

A BEAUTIFUL DWARF PHLOX.

ONE of the most attractive herbaceous plants at the present time is Lapham's Phlox, P. divaricata Laphamii. The soft blue flowers are borne in great profusion from 1 foot to 18 inches high, and it is worthy of a place in all gardens. Grown in a mass, it reminds one of a large cluster of blue Plumbago,

GARDENING FOR BEGINNERS.

SUGGESTIONS FOR SUMMER FLOWER-BEDS.

OPINIONS in reference to methods or plans of bedding out may possibly long continue to vary in a more or less degree, but I venture to think that the

SUGGESTED DESIGN FOR A SLOPING BORDER. SEE TEXT FOR DETAILS.

majority, at any rate, of amateur gardeners have come to the conclusion that the once general (I had almost said universal), and therefore favourite, because fashionable, formal "straight-line" system is *not* the most pleasing, because, generally speaking, *not* the most artistic, the result being the opposite of restful to sensitive temperaments. In the matter of laying out our gardens there is no doubt that the nearer the approach to the ways of Nature herself, the more satisfactory all-round results shall we obtain. It is, of course, admitted at once that the "straight-row" method is the easiest to arrange; but this being practically its only recommendable point, the present-day gardener who wishes for quality in arrangement, as well as in culture, of his plants will not grudge a little extra time in introducing his own individuality into his beds and borders. This is really the burden of the suggestions contained in this article, for probably no given plan will meet the desires or requirements of any in every respect. A practical illustration or two, however, may possibly serve some useful purpose as a sort of basis, alterations and variations from which, both in form and flower, can be made to suit individual tastes.

Fig. 1 is a suggestion of double-lace pattern for a sloping border, the back rows of which could be composed of, say, Marguerites in two shades of colour, and the front rows planted with duplex shades of *Nemesia*, care being, of course, taken to choose well-blending colours in every case of intermingling. In the front gaps *Violas* could be planted—one colour in each space—and a half-standard *Fuchsia* placed in the centre dot spaces.

In Fig. 2 the central triangular line could be composed of *Nicotiana* hybrids, with early flowering *Cosmos* in the three dot spaces. The next cross-over rows might consist of two colours of *Antirrhinums*, the front being edged with *Ten-week Stocks*, and *Lobelia* used as a border.

Fig. 3 is illustrative of a style which can, of course, be filled according to taste, each space marked out representing a bed of one variety, with dot plants of taller growth placed in the background, and having a border of some dwarf species.

B. W. LEWIS.

FORGET-ME-NOTS FROM SEEDS.

EVERY garden should contain Forget-me-nots. They are among the daintiest of spring flowers, and very easy to grow successfully. The plants will thrive and blossom freely in moist soils and positions in sun, and where not too heavily shaded if the ground is moist. Use the Forget-me-not or *Myosotis* freely in the spring bedding schemes

associated with Tulips, and in company with Wallflowers and Polyanthus. Scatter the seeds on vacant ground in the shrubbery borders, and sow freely in the wild garden and woodland. Once sown in favourable surroundings, self-sown seedlings come up in quantity annually. In small town and suburban gardens Forget-me-nots may be used to brighten up what are otherwise rather dull corners where few plants will thrive, such, for instance, as the sunless damp north border, tufts among hardy

Ferns, and the shady front garden. The pale blue *Myosotis alpestris* is very popular at Kew, where it is freely used to carpet the ground beneath deciduous shrubs, one particularly effective combination being a bed of the pale pink-flowered *Tamarisk* (*Tamarix tetrandra*) above the blue-flowered *Myosotis*. Another lovely contrast is a

DESIGN FOR A SUMMER BED TO CREATE A BOLD EFFECT.

bed of *Myosotis* and tall yellow Tulips, Mrs. Moon or Parisian Yellow, for instance.

Time to Sow.—June is the month to sow Forget-me-not seeds. Sow where the plants are to flower, or on a spare piece of ground from which the seedlings can be transplanted in September or October to the flowering positions. Self-sown seedlings and those sown where they are to flower should be thinned to allow the plants to attain their full size and beauty. Naturalised in the wild garden and woodland, thinning is seldom attempted; but in the garden proper the reward of liberal thinning is seen in larger, more vigorous plants, freely branched and covered with good-sized flowers. When planting *Myosotis* in beds and borders, set them out 3 inches to 4 inches apart. Though, as previously noted, Forget-me-nots thrive in most soils, it pays to give the ground a dressing of manure previous to planting, or a watering with liquid manure at the beginning of April, when the flower-spikes are pushing up.

Varieties.—Several species and a considerable number of varieties are grown in gardens. The one illustrated on page 296 is *M. alpestris*; the early Forget-me-not is *M. dissitiflora*; the common Forget-me-not, *M. palustris*; and the Wood Forget-me-not, *M. sylvatica*. These are the best for the pleasure grounds and shrubberies. Then for the flower-beds the seedsmen have given much time and thought to the raising of improved varieties. These include Perfection, bright blue, rose, and white; *Victoriæ*, erect growing and freely branched, sold in three colours, blue, white, and rose; Royal Blue, a lovely dark indigo blue; Star of Love (Love Star), dwarf, bright blue; Dwarf Blue (*nana compacta*); and Dwarf White, useful for edgings to beds and borders.

Myosotis in Pots.—To decorate the greenhouse from Christmas onwards and to supply a few cut flowers for decoration in midwinter, seedsmen have been working on a special strain of Forget-me-nots for pot culture. The plants may be grown in a frame and cold greenhouse, but are better if the greenhouse is just heated sufficiently to keep out frosts. Sow the seeds in a frame during June. Grow three plants in a triangular fashion in a 5-inch pot and place in a cold frame till November, when they should be moved to the greenhouse shelf. The seeds are usually sold under the name of the Pot *Myosotis*.

AGAPANTHUSES FOR THE OUT-DOOR GARDEN.

THESE attractive blue-flowering plants, so often grown in tubs for standing on terraces and walks, may now be removed from their winter quarters and placed in the open. Old-established plants will benefit by top-dressing, previous to which a quantity of the surface soil may be removed. During the season they should be frequently watered with liquid manure.

CALCEOLARIA MRS. GLADSTONE.

ALTHOUGH *Calceolarias* of the bedding class are not nearly so much required as they were a few years ago, when they were frequently employed, they are still essential in many gardens, and anything out of the usual run of colouring or appearance in other respects is appreciated. One of the finest we have ever seen is a most effective variety called Mrs. Gladstone. It originated in the Vale of Leven, where it was raised by an amateur, and it has been greatly

A BORDER WHERE PLANTS SHOULD BE MASSED IN THE CENTRAL SPACES.

admired wherever seen. This Slipperwort has large flowers of crimson, deeply margined with gold, while its height is a foot to 15 inches or 18 inches. It is almost hardy, and the shelter of a cold frame is quite sufficient for it in ordinary winters. It is found most valuable in some of the Glasgow parks, such as in the old garden of Ibrox Hill in Bellahouston Park.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Midseason Vines.—In well-drained borders these Vines will now require liberal supplies of water, and some stimulant must be given to encourage the growth of large berries. It is well to vary the stimulant from time to time, and always guard against overdoing it. Promote a moist atmosphere and a free circulation of air while the weather is favourable. Thin out lateral growth so that the foliage may not become overcrowded.

Late Vineries.—All late Grapes should be thinned as soon as possible, and when this has been accomplished the borders should be lightly pricked over and a good watering of manure-water from the farmyard given, and after a few days a mulching of decayed manure should be applied. Ventilation must have careful attention, especially in the early morning.

Early Peach and Nectarines Trees in Pots.—Most of the fruits will have been gathered from early trees, which will require careful attention in order to prepare them for next season's forcing. Remove the trees to their summer quarters, and allow plenty of space between them. Do not allow them to suffer from want of moisture at the roots, and syringe the foliage frequently in dry weather. Early permanent trees should also receive liberal treatment. Remove all worthless growth which is not required for next season's work, and use the syringe freely among the foliage to keep it in a clean, healthy condition, the ventilators being left open night and day.

Strawberry Plants in Pots should now be grown in the coolest position available. Keep them from coming in contact with permanent trees, or they may become infested with red spider in consequence.

Plants Under Glass.

Crotons.—Plants raised from early struck cuttings will be ready for potting into 6-inch pots. Protect from sun until the plants have become established in the new soil, after which they may be fully exposed to the light, and the syringe freely used among the foliage. Close the house early in the afternoon, allowing the temperature to rise to 90°.

Gardenias.—Plants which have finished flowering should be carefully cut back, removing all spindly growth. It is a mistake to retain old, worn-out plants, as the blooms are always small and the foliage of an inferior colour. In making new plantations it is well to provide a mild and lasting bottom-heat in order to give the plants a good start; and for this purpose nothing is better than a bed of well-prepared Oak leaves, which should be trodden tightly together, after which a layer of turfy loam and leaf-soil ought to be placed over the surface to the depth of 1 foot. Young, healthy plants should then be put out, allowing a space of 2 feet between them.

Liliums.—Plants which are growing freely should be well supplied with weak liquid manure. Place a neat stick to each plant, and keep a sharp eye on aphids, which must be destroyed at once.

Salvias may now be potted into their flowering pots. If once allowed to become pot-bound in the early season it is a difficult matter to restore them to a good colour. After potting they should be placed in a cool pit until they are well established, after which they may be grown in the open on a bed of sifted ashes. An occasional watering with weak soot-water will do much to improve the colour of the foliage.

The Flower Garden.

Dahlias.—These may be planted at once, selecting varieties as near the same height and colour as possible for each bed. Staking must be attended to as soon as the plants have been placed in position, but, in the case of small plants, only short sticks may be used at first, leaving the final staking until a fair amount of growth has been made.

Sweet Peas coming into bloom will benefit by frequent applications of manure-water from the farmyard, after which the soil should be stirred with a Dutch hoe, and if dry weather prevails,

a mulching of some kind will do much to retain the moisture in the soil.

Summer Bedding.—By this date all bedding plants will be sufficiently hardened to be planted out, and the work should be pushed forward with as little delay as possible, leaving the tender subjects until last. Water the soil a day before planting, and again after the plants are put out; and if dry weather prevails, the syringe may be used with good effect in the evening or as soon as the sun has passed from the plants. Care must be taken that none of the plants suffer from want of water before they are placed in their final positions.

The Kitchen Garden.

Celery.—The trenches should now be got ready for the early batch of Celery. Give a liberal supply of well-decayed manure, and cover with 4 inches of the finest soil available. When the plants are ready to put out, they should be carefully lifted with a good ball of soil to each plant, and planted firmly in the trenches, after which a good watering must be given, and this ought to be repeated in a few days if necessary. When dry weather prevails, the syringe should be freely used among the plants, and a dusting of soot may be given to keep insect pests in check.

Autumn-sown Onions.—The soil between the rows should be stirred with a Dutch hoe, and if showery weather prevails, a dusting of artificial manure may be given. Spring-sown Onions should be treated in a similar manner, and the plants thinned to 4 inches apart.

Leeks.—The main crop of Leeks should be planted at once, and allowed a space of 15 inches between the rows. Plants which were put out early may now be watered with liquid manure.

Chicory.—The latest batch of Chicory should now be sown, and as soon as the plants are large enough they may be thinned to 9 inches apart. Keep the soil well stirred with a Dutch hoe during the summer to keep small weeds in check.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Parsley.—As the earlier sowings frequently run to seed, in order to have a continuous supply of this indispensable garnishing throughout the year it will be necessary to make a sowing now. As this sowing will have to stand the winter, the seed should be sown in such a position that it can be easily protected in severe weather. Remember that Parsley requires plenty of room to develop, so that it will be well to sow thinly, and afterwards do not be afraid to thin out the young plants so as to avoid overcrowding.

Endive.—Although this may be sown earlier or even later than this date, the present is a suitable time to make the main sowing, as, by thinning out the seedlings from time to time, this will give a succession over a long period. To secure good crisp heads, the seed should be sown on a light, sandy soil that has been previously manured. Sow in drills 1 inch deep and 9 inches apart, and, should the weather be dry, water the bed from time to time.

Broad Beans.—Under ordinary circumstances this might seem rather late to make a sowing; still, if ground is available, it will certainly be worth a trial. Before sowing, the Beans ought to be soaked in tepid water for a few hours, and should the soil be dry, water the drills before putting in the seed. As in the case of the earliest sowing, top the plants as soon as a sufficient number of flowers have set. I have seen a very useful crop gathered from a sowing made at this time.

Herbs.—All those that were sown in boxes or frames should now be planted out, and for this purpose select a rather shaded part of the garden. Except for giving an occasional watering in dry weather and keeping down weeds, this will be all that is required for the season. To increase the stock of such herbs as Sage, Mint, Lavender and Thyme, cuttings may be inserted now either in frames or in some sheltered corner in the garden.

Some of these will make nice plants the following season.

The Flower Garden.

Begonias.—Young plants raised from seed sown in January and intended for bedding purposes may now be planted out on a border that has previously been enriched with well-decayed manure and leaf-soil. These will provide a good display in the autumn, when a selection can be made of the best of the various shades of colour and carefully noted. Some of the best of the plants can be lifted and potted while in bloom. These will be found to be very useful for furnishing the greenhouse. It is really surprising how long they will last in flower treated in this way. I have also found the flowers exceedingly useful for dinner-table decoration, and a very rich effect they produce.

Carnations.—The staking of these should be attended to without delay if this has not been previously done. When this work is delayed, there is great risk of the flower-spikes getting broken when trying to get them into an upright position. For staking I can confidently recommend the spiral green-painted ones now on the market. The work can be more expeditiously done with these than with the ordinary green-painted ones. They are much neater, and I am not sure that they are not cheaper in the end. When the staking is completed, give the ground between the plants a dusting of soot or Carnation manure, afterwards running the Dutch hoe through them.

Plants Under Glass.

Hippeastrums (Amaryllis).—Most of these will have passed out of flower, and should be removed to a house of greenhouse temperature to complete their growth, after which they may be gradually dried off. But it should be remembered that they must on no account be allowed to become dust dry at any stage. During the resting period they may be placed in a cold frame and ventilated during the day.

Begonias.—Those intended to give a display in the late summer will now be sufficiently advanced in growth to have artificial feeding given. For this purpose perhaps there is nothing better than ordinary liquid manure, although an occasional sprinkling of an approved fertiliser would also assist them. There is still time to put in cuttings of the fibrous-rooted sorts for winter flowering. When rooted, the utmost care must be exercised in watering, and guard against insect pests, which, if allowed to get a hold, will seriously cripple the young plants.

The Hardy Fruit Garden.

Peaches.—The pinching and regulation of shoots of Peach trees under glass usually receives timely attention, while those grown on a south wall out of doors are very often neglected in this respect, yet it is equally important that they should be attended to in this very necessary work. Therefore go over the trees now and remove all superfluous shoots, as this will not only assist the swelling of the fruit, but make room for the young growth that is to supply next season's crop.

Cherries.—The most forward of the early varieties will now be beginning to take on the second swelling, so that it will be necessary to protect them from the ravages of blackbirds at once. It is extraordinary what damage these birds do among the fruits, even if the fruits are only partially coloured. If the trees are against walls, they are easily protected with an ordinary net, but some difficulty will be experienced in protecting standards.

Fruits Under Glass.

Peaches and Nectarines Stoning.—The most frequent causes of fruit dropping at this period are overcropping and undue excitement. As a general rule, among large-fruited varieties one fruit to every square foot of surface covered by the tree will be ample. Avoid anything in the nature of overcropping. A medium crop is the safest guide, and during the whole of the stoning period maintain an even temperature. Under these conditions the dropping of fruit is reduced to a minimum.

JOHN HIGGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetown Gardens, South Queensferry, N.B.

SOME GOOD FORGOTTEN GREENHOUSE PLANTS.

IT is at least questionable whether in the search after novelties we do not ignore the merits of some good old greenhouse plants which were very popular in days gone by. Some of them at least would well repay a revival in their favour, and would doubtless be much admired if brought forward once again in good condition. Difficulties attending their cultivation are, no doubt, answerable for many subjects dropping out of cultivation, but what was possible in days gone by should certainly not be such a difficult matter with improved glass structures, heating and other appliances. In recalling some of the favourites of bygone days, the following suggest themselves as a few of those whose almost total disappearance from gardens is a decided loss.

Burchellia capensis.—An evergreen shrub, clothed with dark green, ovate leaves and bearing bright scarlet, tubular-shaped flowers at the points of the shoots. The "Dictionary of Gardening" refers to it as a stove plant, but it will thrive perfectly in the warmest end of the greenhouse, where, however, it is a little later in flowering than in the stove. Needs a mixture of loam, peat and sand.

Canarina Campanula.—A herbaceous plant which, from a stout rootstock, in winter pushes up a sturdy stem, on which the flowers, in colour yellowish with red nerves, somewhat suggestive of an Abutilon, are borne during the early months of the year. Thrives in a mixture of loam, leaf-mould, well-decayed manure and sand in an ordinary greenhouse.

Cedronella canariensis.—This, also known as *Dracocephalum canariense*, is popularly termed the Balm of Gilead. Its attractive feature is the delicious fragrance of the leaves when gently rubbed. Cut sprays of this used to figure in the old-fashioned nosegays at one time so much in vogue. Soil: Loam, leaf-mould and sand. Thrives in the greenhouse.

Chorizema Henchmannii.—One of the most beautiful and distinct of all the Chorizemas, and, withal, one of the most difficult to grow. Though it occurs in the "Kew Hand List," it has almost dropped out of cultivation. Soil: Peat, loam and sand. Does well in an ordinary greenhouse.

Elæocarpus cyaneus.—A small Australian evergreen tree that will, however, flower freely in a small state. The drooping, bell-shaped flowers are pure white, and beautifully fringed at the edges. This furnishes a good illustration of an old plant being rejuvenated, for it was introduced over a century ago, and yet was comparatively unknown when brought forward by Messrs. Veitch a few years since. It then obtained a first-class certificate from the Royal Horticultural Society. Grows and flowers well in the greenhouse in a mixture of loam, peat and sand.

Eustoma russellianum.—Under the name of *Lisianthus russellianus* this North American Gentian Wort used to be regarded as a good test of the cultivator's skill. The most satisfactory results were obtained by treating it as a biennial, when the comparatively large rich purple blossoms were borne in great profusion. Seeds should be sown in June and the plants treated much the same as *Schizanthus*, that is, put in their flowering pots in February. Soil: Loam, leaf-mould and sand. It requires a greenhouse temperature.

Fugosia hakeæfolia.—An Australian member of the Mallow family with curious narrow leaves, and large purple lilac blossoms borne during the summer months. From its uncommon appearance it is sure to arrest attention. Of easy culture. Needs an ordinary soil in the greenhouse.

Hovea Celsii.—Though now known by the specific name of *Elliptica*, this plant in olden days was much grown as *H. Celsii*. Of the hard-wooded plants at that time popular, it was looked upon as a difficult subject to grow. It belongs to the Order Leguminosæ, and the rich blue Pea-shaped flowers are borne in clusters from the axils of the leaves. Needs a mixture of peat and sand, careful watering, and a greenhouse temperature.

Lagerstrœmia indica.—This, which is sometimes known as the Crêpe Myrtle, is a deciduous shrub, introduced from China about a century ago. It is more fitted as a good-sized bush in the conservatory than as a smaller specimen, as when large it flowers freely. The beautiful bright pink flowers with crisped petals are borne in loose panicles during the summer months. Will grow freely in ordinary potting compost in the greenhouse, and in winter, when devoid of foliage, should be kept moderately dry.

Leschenaultia.—The scarlet-flowered *Leschenaultia*, which was introduced from Australia in 1824, was, among hard-wooded plants, considered to be an extremely difficult subject to cultivate successfully. This did not, however, appear to be the case with the blue-flowered *Leschenaultia biloba* major when Messrs. Balchin of Hassocks used to grow it so beautifully in that delightful nursery on the South Downs. Soil: Peat and sand. Needs an ordinary greenhouse.

Nerium Oleander.—Perhaps it is going rather too far to refer to the Oleander as a forgotten plant; but its merits as a beautiful flowering shrub might certainly be more often recognised than they are now. A lover of sunshine, its non-flowering may often be traced to too much shade. Needs a mixture of loam, leaf-mould and sand, and a greenhouse temperature, with plenty of light.

Pavetta caffra.—In the palmy days of Chiswick, half a century or more ago, this was a favourite exhibition plant. It is an evergreen shrub, and the rounded clusters of white flowers, with long, prominent styles, are borne in great profusion in the summer. This *Pavetta* is nearly related to the *Ixoras*, which it much resembles. Will thrive in ordinary potting compost in the warmest part of the greenhouse.

Pleroma elegans.—This South American Melastomad has large blossoms of an intensely rich blue colour. Like some other members of the genus, it is not very amenable to cultivation. Still, shown as it used to be, it would, I think, gain universal admiration. Soil: Peat and sand. Good drainage, plenty of water when growing, a moist atmosphere and a greenhouse temperature are needed.

Russellia juncea.—A peculiar Rush-like plant, with drooping racemes of small tubular-shaped, scarlet flowers. Needs an open peaty soil, with plenty of water, and the warmest part of the greenhouse.

Trichinium Manglesii.—This, which belongs to the Amaranth family, is of a perennial nature. The inflorescence resembles large, oblong-shaped tufts of whitish hairs, whence pink tips protrude. Though at one time fairly well known, it is now, outside of a botanic garden, rarely seen.

Soil: Loam, leaf-mould and sand. It should have a light position in the greenhouse.

Tropæolum.—It may, perhaps, be considered by some that the *Tropæolums* are not a neglected class; but the tuberous kinds, such as the pretty blue *T. azureum* and *T. tricolorum*, with its scarlet and black blossoms, might well be more grown than they are now. Kept dry when dormant, they may be potted in September in a mixture of loam, leaf-mould and sand. Greenhouse.

These notes on old-fashioned greenhouse plants might be considerably extended, but enough has been given to show that we might do worse than allow some of them to occupy the position in gardens that they once held.

H. P.

A SCOTTISH LADY GARDENER.

NOT many of our most enthusiastic lady horticulturists are more worthy of recognition in the columns of THE GARDEN than Mrs. McDouall of Logan House in Wigtownshire.

With the assistance of her son, Mr. Kenneth McDouall, the cultured and genial proprietor of the Logan estates, and the able superintendence of her head-gardener, Mr. R. Findlay, she has made Logan and its noble environment a centre of attraction during the summer and autumn to crowds of deeply interested visitors. Mrs. McDouall, like all true lovers of Nature, is greatly enamoured of flowering trees and shrubs, Azaleas, Rhododendrons (of which she has a splendid collection), Cherries, Laurels and Solanums being special favourites. Ipomœas, Allamandas, Bougainvilleas and exquisite climbing Roses and Heliotropes adorn the conservatories. Among the fruits specially cultivated in the extensive hot-houses are Vines, Peaches, Oranges, Nectarines, Figs and Guavas. One of her latest and loveliest acquisitions is a pond for the cultivation of the finest *Nymphæas* in the centre of the garden, in which also the reflections of the enviroing trees and flowers on a calm evening in June are beautiful beyond description. The two large rock gardens—the creation of Mr. Findlay—are supremely fascinating about the beginning or middle of May, when such beautiful *Primulas* as *japonica*, *pulverulenta*, *cockburniana* and *bulleyana*—not to speak of a myriad other flowers of intensely contrasted colours—are to hundreds of visitors as a veritable revelation of floral and artistic capability.

Mrs. McDouall, like her accomplished brother, Sir Archibald Hepburn, has always been a great cultivator of Roses and Oriental Lilies. Of the former she has nearly all the more modern varieties, though she still adheres lovingly to many of her first favourites, such as *Mme. Abel Chatenay*, *Captain Hayward*, *Viscountess Folkestone*, *Duke of Edinburgh*, *Caroline Testout* and the incomparable *La France*. Among the Lilies, which are most successfully cultivated in the spacious gardens at Logan House, are the Himalayan *giganteum*, the Persian and Caucasian *monadelphum szovitzianum*, *pardalinum* (for the most part rare hybrids from the Californian *Panther Lily*), *auratum platyphyllum* and *virginale* (which are grown here superbly), *candidum* (which Mrs. McDouall grows with refined artistic instinct among pink and scarlet Roses), *Henryi*, *Hansonii*, *longiflorum Wilsonii* and *speciosum magnificum*. It only remains to be recorded that Logan House

has a noble environment of woods, in which Limes, Larches, Laurels, Chestnuts, Hawthorns, Cedars, Oaks, Pines and Sycamores are conspicuous, from the midst of which it looks out majestically over a beautiful miniature lake across the luminous Bay of Luce to the Minnigaff Mountains, that grandly bound the horizon. Overlooking a fine avenue of young *Dracænas* from an elevated terrace of the garden (like the hoary past contemplating the aspirations of the present) is an Ivy-covered fragment of the ancient castle, where in the memorable language of Thomas Gray: "The moping owl doth to the moon complain, Of such as wandering near her secret bower, Molest her ancient, solitary reign."

DAVID R. WILLIAMSON.

INDIAN AZALEAS.

VERY few of the hard-wooded plants so much grown at one time have retained their hold on the public, but still there are some. Occupying the foremost place come the different varieties of the Indian Azalea, which are probably grown now in even greater numbers than they were before. There is, however, a vast difference in the plants, for whereas now most of them are in the shape of neat, naturally grown bushes, grafted on to clear stems from 6 inches to 9 inches in height, in bygone days they were largely grown as formally trained standards or pyramids. As a youngster I was taken to the great International Horticultural Exhibition at South Kensington in 1866, and nothing made so great an impression on my boyish mind as the trimly trained Azaleas with their masses of colour. Now, however, plants of a hard formal outline are not appreciated; hence Azaleas of this class are by no means popular. True, standard-grown plants have come somewhat to the fore within the last few years; but in their case the heads are to a great extent allowed to grow in a natural manner.

Though Azaleas in the shape of comparatively small plants are now so largely flowered in this country, they are nearly all propagated and grown in Belgium, where in some parts their culture forms a thriving industry. They are planted out in a light, spongy soil largely composed of leaf-mould, in which, with unremitting care and attention, they grow luxuriantly and set their blossoms freely. Early in the autumn they are carefully lifted and immense numbers sent to this country. The large, loose masses of roots are, to the uninitiated, somewhat of a puzzle to get them into pots of reasonable size, or even comparatively small ones, as is often done. Where the mass of roots is too large, it may be safely reduced to more reasonable dimensions, and by pressing together—which from its light, open nature is readily done—the plant can be accommodated in a pot of suitable size. After potting, the plants must be kept rather close and shaded, giving a syringing two or three times a day. They must also, of course, be thoroughly watered. In this way the young hair-like roots will soon recover from the check of removal and become established.

A notable feature of the Indian Azaleas is the length of time over which their flowering season extends, for if due care is taken in the selection of varieties, their showy blossoms may be had for nearly, if not quite, one-half of the year.

For a long time the double white-flowered variety *Deutsche Perle* was regarded as the earliest of all, but an even more precocious kind has been very much in evidence within the last few years. This is *Mrs. Petrick*, whose semi-double flowers are of a deep rose colour. A class of Azaleas just now very popular are those varieties whose blossoms are of a deep rose or salmon rose tint, with a light-coloured centre and margin, this last being often prettily crisped. One of the earliest of these to flower is *J. B. Varonne*, while among the latest is *schryveriana*. A desirable midseason kind is *President Oswald de Kerchove*, which is very much grown. With regard to a selection of varieties, it is a difficult matter to advise upon, as opinions vary greatly. The better way, when it can be done, is to select the plants when in flower, for there is now a long list of beautiful kinds from which a choice can be readily made. One thing, however, which may be noted is that as white flowers are much appreciated, the merits of *Niobe* for late flowering must on no account be omitted. The blossoms are double and of a somewhat ivory white tint.

A method which has cropped up within recent years of growing some of the small-flowered kinds, but especially the bright carmine crimson variety *Hexe*, is to strike them from cuttings, under which treatment they form dwarf, bushy plants in quite small pots, and when crowded with blossoms they meet with a ready sale. Other varieties are grown in the same way, but none is so popular for the purpose as *Hexe*, which was cultivated in limited numbers for years before its merits for this mode of treatment brought it prominently forward.

Repotting.—Annual repotting is by no means necessary; indeed, old-established plants will grow and flower for years in a satisfactory manner without being disturbed at the roots. Complaints are by no means infrequent of non-success in the culture of the Azalea, and this, no doubt, arises, in many instances at least, from a period of neglect immediately after flowering. This is the most critical time with Azaleas, as they should then be encouraged to make their growth for another season by keeping them somewhat warmer than before, and by frequent syringing in order to prevent thrips attacking the leaves. Should the plants need repotting, this must be done as soon as the flowers are over. A suitable compost is fibrous peat and sand, while some prefer a little loam mixed with it. In any case, the new pot must be clean, effectually drained, and sufficiently large to allow of some fresh soil between the old ball of earth and the side of the pot. This fresh soil should be rammed down very firmly and evenly, taking care that the main stem is not buried deeper than it was before. W. T.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Twickenham Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Twickenham Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ASTERS NOT DOING WELL (*D. W., Surrey*).—We can find nothing wrong with the Asters except that they appear rather yellow. This may be due to overwatering, to lack of light, or to lack of potash, and we suggest watering the plants with a solution of 1oz. of sulphate of potash or half an ounce of sulphate of ammonia to a gallon of water once a week.

TULIPS FAILING (*York*).—We fear your Tulips are being attacked by the fungus *Sclerotinia parasitica*, and that the soil is infested with the resting bodies which that fungus produces. The only thing to do will be to remove the soil thoroughly now or in early autumn to a depth of 3 feet and replace with fresh, unless you are willing to forego the growing of Tulips for two or three years.

TREES AND SHRUBS.

AZALEA TO NAME (*R. F. C.*).—One of the Ghent Azaleas, a hybrid containing a good deal of the blood of *A. nudiflora*, or, correctly, *Rhododendron nudiflorum*.

KITCHEN GARDEN.

CULTURE OF THE CARDOON (*W. B.*).—Plant out in rich soil 3 feet apart (if more than one row is wanted they should be 5 feet apart, as much soil is required for earthing up), and maintain a free growth by occasional soakings of water. The leaves should be secured to stakes as they grow in height. About the middle of August the plant will have attained to its full growth, and the blanching process should then be begun. This is done by gathering the leaves together and tying loosely to stakes; then wrap round loosely with leaf-bands, finishing by earthing up with soil to a height of 2½ feet or 3 feet. The blanching will be completed towards the end of October, and the midrib of the leaf, which is the portion to be cooked, will be ready for use.

MISCELLANEOUS.

YELLOW AND BROWN MUSTARD SEED (*Y. Z.*).—There are two kinds of Mustard grown for commercial purposes, *Brassica alba* and *B. nigra*. The seeds of the former are yellow, while those of the latter are brownish. The seeds of the two kinds are usually mixed before grinding for commercial mustard, but when ground separately the seeds of *B. nigra* produce a much darker powder than those of *B. alba*.

LARVÆ OF WINTER MOTH (*E. J. H.*).—The grubs are the larvæ of the winter moth. This insect attacks a large variety of trees, and all the fruit trees are subject to its attack. It would be well to spray the trees immediately with lead arsenate solution, made according to the directions furnished with the material as bought from the sundriesmen. This spray material, which is, of course, very poisonous, should be purchased in the paste form.

SOIL PESTS (*Rev. W. E. O.*).—We think your best plan will be to make holes at intervals of a yard on both sides of the row of Sweet Peas and about nine inches to twelve inches away from the plants, and pour into each a teaspoonful of carbon bisulphide. The holes ought to be about eight inches or nine inches deep, and should be covered in immediately the liquid is poured in. The fumes will then diffuse in the soil and kill the insects without damaging the roots of the Sweet Peas. It is important to keep the liquid, which is very deadly to animal life, as far as possible from a light, even that of a glowing cigar, as it is extremely inflammable, though the temptation to smoke while using it is great, owing to its evil odour.

NAMES OF PLANTS.—*F. W. A.*—1, *Heuchera sanguinea*; 2, *Asperula odorata*.—*W. E. P.*—*Scilla peruviana*.—*Mrs. Sartorius*.—1, *Rubus deliciosus*; 2, *Prunus cerasifera*.—*Good Husband, West Riding*.—1, *Phlox amœna*; 2, *Sedum roseum*.—*F. M., Bucks*.—*Veronica gentianoides*.—*H. B.*—1, *Spiraea van Houttei*; 2, *Polygonatum biflorum*; 3, *Saxifraga canaliculata*; 4, *Fuchsia*, garden variety; 5, *Phyllocactus Ackermannii*; 6, *Iris pallida*.—*C. R. W., Cornwall*.—*Tricuspidaria dependens*, syn. *Crinodendron hookerianum*.

THE GARDEN.

No. 2221.—VOL. LXXVIII.

JUNE 13, 1914.

NOTES OF THE WEEK.

New Fellows of the Royal Horticultural Society.—At the meeting of the above society held on Wednesday, the 3rd inst., 230 new Fellows were elected. We understand that this number has only been exceeded once before.

Roses and Clematises.—A very charming effect can be obtained by planting the Mountain Clematis, *C. montana*, and the beautiful Rose Carmine Pillar so that they may ramble together at will. The instance we have in mind is where they have been growing for some years over an old Ivy-covered summer-house in a wild, careless way without receiving any attention.

The Iris Border at Clandon.—Irises have long been a feature of the beautiful gardens at Clandon Park, Surrey, and seldom has the Iris border looked better than at the present time. The border runs by the side of a lake. *Iris sibirica* and its varieties are grown by the lakeside with their roots in water, while those Irises belonging to the *germanica*, *pallida*, *squalens* and *flavescens* sections are now freely flowering in the border. One remarkable feature of the border is that in the great wealth of bloom some varieties are flowering that have not done so for years.

The Burning Bush.—This interesting plant, known by the botanical name of *Dictamnus Fraxinella*, is one of the most striking and interesting herbaceous plants in flower at the present time. Its stately, erect spikes of either white or purplish flowers stand out very conspicuously. The hot, dry weather does not in the least affect either flowers or leaves, and they will remain fresh for some time either growing or cut. Apart from this, the plant does not grow to any great size, which is an advantage for small gardens. It is an excellent subject for naturalising in the wild garden, and derives its common name from the fact that in the evening, after a very hot day, fumes are given off, which will sometimes ignite when a lighted match is held just over the plant.

A Beautiful Dwarf Pink.—One of the most attractive features in the rock garden at Kew just now is a colony of Pink Spencer Bickham. The plants are situated by the steps leading from the Orchid-houses, and are creating quite a blaze of colour. This variety was raised some years ago by crossing the Cheddar Pink (*Dianthus*

cæsius) with the Maiden Pink (*D. deltoides*). The flowers in size and shape resemble those of the first-named parent, but are of a much more brilliant rose colour. It is a Pink that ought to be much better known than it is. In common with most others of its race, it needs well-drained soil, but beyond that does not present any serious cultural difficulties.

An Uncommon Hardy Annual.—Why is it that *Collomia coccinea* is so seldom seen in

almost any kind of soil, and we commend it to those of our readers who appreciate dainty flowers. It is interesting to find a native of Chili withstanding our winters.

Rose Conrad F. Meyer.—What a glorious Rose this hybrid *rugosa* is! Anyone who wants a strong-growing variety to scramble over trellis or rustic poles, or to climb the side of the dwelling-house, should make a note of it now to plant next autumn.

We have had a young bush flowering for the last month, its large, full, silvery pink flowers being produced in abundance. As these emit the true old-fashioned Rose perfume, and that in bountiful degree, we have no hesitation in proclaiming it one of the best pillar or rambling Roses. It is also good in the autumn.

Dwarf Flowering and Berried Shrubs.—The *Pernettyas* are attractive shrubs, and are worthy of notice for the beauty of their berries during the winter months. But apart from the fruits they are worthy of recognition at the present time, when they are laden with their small, Lily-of-the-Valley-like flowers. Owing to the waxy texture of the blossoms, they remain in good condition for a long time if small sprays are gathered and placed in water just as the blossoms are about to expand. The purity of the blossoms makes a striking contrast to the reddish colour of the bark and the dark green of the mature foliage. *Pernettyas* are well worthy of a place among flowering shrubs, and will succeed in any soil providing it is free from lime.

A Charming Bramble for the Rock Garden.—*Rubus arcticus*, the beautiful alpine Raspberry, is an excellent little plant for a damp, shady spot. Although one of the smallest of the genus, only growing from 5 inches to 6 inches high, it is one of the most attractive with its rosy

purple flowers, each the size of a shilling. It is very free, both in growth and in the production of flowers, and a small piece will soon form a large mass. Apart from its attractive flowers, the fruit is also very ornamental when produced in quantity, as well as being nutritious, for Linnaeus in his "Flora Lapponica" states that often, when he was sinking with hunger and fatigue, he was revived by the wine from these berries, and some people in the North of Sweden make a syrup, a jelly and a wine from them.

THE IRIS BORDER AT CLANDON PARK.

gardens? Just now we have a number of self-sown plants that withstood the winter, and each has made quite a small bush from 12 inches to 15 inches high and nearly as much in diameter. Each shoot is terminated by a cluster of vermilion red blossoms, which resemble very much in appearance those of the smaller-flowered *Bouvardias*. From past experience we know that the plants will continue the display over a long period, and will produce seed freely and so perpetuate themselves. This hardy annual will thrive in

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Draba (Petrocallis) pyrenaica.—Surely the note in THE GARDEN of May 23 about this nice alpine is belated, and [therefore misleading. "Just now it is opening its flowers"; with me they are over. It begins to flower in the first week of April; in the third week it is sometimes so closely set with them that hardly a leaf is visible. At the present time it is a bright green cushion. —HERBERT MAXWELL, *Monreith*. [At the time the note referred to was written, i.e., May 18, this plant was in full flower in several gardens in the London district.—ED.]

Hardy Cypripediums.—In the interesting article on this subject (page 271) "W. I." does not mention *Cypripedium mandschuricum* (a beautiful *C. Calceolus* with big flowers), *C. microsaccos* (with brown and pink flowers), and the three beautiful varieties of *C. ventricosum*, *C. v. album*, *C. v. lutescens* and *C. v. roseum*. These three varieties are far the best of all the hardy *Cypripediums*. We had them in flower last week, and everybody who saw the beauty of our sheltered bed was enthusiastic over these three varieties. We grow them under shade in our umbrosum, without any protection in winter, but rather dry. They seem to be hardier and easier to grow than *C. macranthum*.—H. CORREVON, *Floraire, Geneva*.

—The very interesting article on hardy *Cypripediums* which appeared in your issue of May 23, page 271, prompts me to send a photograph of *Cypripedium Calceolus*. It has reddish brown sepals and a yellow pouch. I note that it is referred to as a native species. I have often seen it described as a native plant, but so far have not yet had the pleasure of finding it in the wild state. One work that I have by me says that it grows on the Cotswolds in turf in very gritty, fibrous limestone soil in full sun. I have searched in vain in this and other localities for this plant, and am of the opinion that it is now extremely rare, if not extinct, in the wild state in Nature.—C. Q.

Hybrid Primula Leddy Pilrig.—In reply to Mr. Arnott's note in May 30 issue of THE GARDEN relating to the above Primula, and especially to that part of it which deals with the parentage of same, I assure him that the parentage as given by me is perfectly correct. Had I been in the habit of hybridising at random (which I am not), even then I would have had little difficulty in tracing the origin of the hybrid, as certain distinct characteristics from both parents are clearly stamped on it. For the benefit of readers of THE GARDEN who take an interest in hybrid Primulas, I here give the names of the parents of the hybrid Primula in question. They are as follow: *P. bulleyana* and *P. beesiana*, *P. bulleyana* being the seed parent. The colour of the hybrid combines the purple red of *P. beesiana* with the apricot of *P. bulleyana*. It has a faint Auricula-like perfume,

which it takes from the pollen parent, *P. beesiana*. Apart from the question of parentage of *P. Leddy Pilrig*, I thank Mr. Arnott for his favourable criticism of its merits as a plant.—W. ROBERTSON.

Early Gooseberries and Vegetables.—I began picking Gooseberries on May 7. I also dug Potatoes (*Sharpe's Victor*) and cut a dish of Globe Artichokes on May 30. These were of good size and quality, and both were from the open ground. The late frost has done no damage here. I have been a reader of your valuable paper for years, and have picked up many real helpful hints from its columns.—FRANK MITCHELL, *The Gardens, Beacon Grange, Hexham-on-Tyne, Northumberland*.

A RARE BRITISH ORCHID, CYPRIPEDIUM CALCEOLUS.
THIS IS SELDOM FOUND NOW IN A WILD STATE.

Our Native Flowers.—In your issue for May 30, page 279, there is an interesting letter on the similarity of our native flowers in separated districts. In regard to the Blackthorn, here on the Wiltshire Downs the profusion of bloom was marvellous this spring. Hedges were full of bloom, and small trees only a few feet high were literally crammed with blossoms, the effect of these masses of white standing out against the dark green of the Pines, or mingling with the delicate April green of other trees, being most effective and beautiful. Gorse has been plentiful, but scarcely so abundant as last year, when every bush was a blaze of yellow. Last year, however, Hawthorn was conspicuous by its absence, for, of all the hundreds of trees in the district, not one was seen with

any clusters of bloom. This spring every tree is flowering abundantly, and filling the air with a pleasant fragrance. These trees have not been affected by the bitter wind and severe frost of the 25th and 26th ult., though many wild flowers, such as Campions and Stitchwort, look shrivelled up, and the Bracken in sheltered dells seems scorched as if by fire.—E. A. P., *Wills*.

The Pollination of Fruit Trees.—The recent importation of Dutch bees should, apart from the profit of honey produced, also prove of considerable assistance to fruit-growing. Late frosts, insect and fungoid pests may account for many fruit failures, but I venture to say that non-pollination is the cause of not a few. Certain it is that where bees are kept, fruit sets more freely. To this most of us will agree. For example, as to distribution of pollen, take the wet flowering season of last year and the poor crop that followed. The same period of this year, though not without its frosts, particularly sharp on May 2, but dry, and pollen easily distributed, resulted in the splendid prospects of a fruit crop this year. Also, some varieties of fruit trees, being self-sterile, require the pollen from another variety which may be some distance away. In this case the help of the bee is most useful. Growers of fruit under glass have their artificial means of pollination, not trusting to chance. Fruit in the open is dependent in this respect entirely on natural agencies, which may be assisted by bees. Therefore the introduction of still larger quantities of bees should be welcomed, and growers, cottagers and others encouraged in every way to keep them.—F. MARSHALL.

Emmerton on the Auricula.—In THE GARDEN for May 30, page viii., your correspondent G. F. W. Herbert, in his notes about Isaac Emmerton, which originally appeared in Hogg's Supplement to his "Treatise on Florists' Flowers," falls into an error where he says that Emmerton's famous treatise on the Auricula was published in 1818. Emmerton published the first edition of that work in 1815, and the second appeared in 1819. Although Hogg claims to have had some share in the writing of it, yet on reading Emmerton's preface it is not apparent that it was other than an independent effort of his own, and Emmerton was dead when Hogg's Supplement was published. There is nowhere any record of an 1818 edition, and probably that date may have been a mere slip of the pen on the part of your correspondent or a printer's error. Both Johnson and Lady Amherst, in their bibliographies, give the year 1816 as the date of Emmerton's publication, but this date cannot have been verified. Johnson makes no reference to a second issue, while Lady Amherst does, and places it under its proper date, 1819. The first edition is exclusively an Auricula treatise, but the later one contains chapters on the Polyanthus, Carnation, Pink and Ranunculus. Both editions are in my library, and the dates given by me are unquestionable.—C. H. P.

Protecting Fruit Blossom.—We gardeners in the North are much interested in the notes about the protection of fruit blossom during the early months of summer. It may prove surprising to readers who live in the sunny South to know that I have to protect my Pears here; if I did not, the crop would be infinitesimal. Last year I had twelve large sashes over my choicest kinds, and the others were protected with mats; but, in spite of all that, the crop was far from satisfactory. Of course, it must be mentioned that the soil is not of the highest order for Pear-growing, since it is heavy and cold; yet, after many years' "manufacture," it ought to be fairly good now. Most of the trees are on the east and north walls, and so sheltered from the worst winds (near Glasgow). For the past six years I have been trying to find a good variety outside the older sorts that will suit my place; but, though I have patronised nurserymen in all parts of the country, I have not yet had the satisfaction I desire. The laborious practice of protecting the trees during their period of bloom seems inevitable, and I have resigned myself to the unlucky Fates which planted me—and the Pears—in an uncongenial district.—H. H. A., *Glasgow*.

Vitality of Seeds.—With regard to this subject, referred to by Mr. Charles Comfort on page xx. of *THE GARDEN* for May 23, I may, perhaps, be allowed to add a few words to show that some seeds more than others have a tendency to retain their vitality for long periods before germinating, and are more or less constant in this habit. Many years ago I visited the extensive grounds of Mr. Rufus Usher at Bodicote, near Banbury, where medicinal plants of several kinds were systematically cultivated. Among these were two forms of Henbane (*Hyoscyamus niger*), the forms being known respectively as annual and biennial. The latter, producing only a large tuft of spreading radical leaves during the first year, is the most valued for its medicinal properties, extract of Henbane being prepared from them. I remember being told at the time of my visit that the Henbane was a very uncertain plant in its mode of growth, as the seeds were often known to lie in the ground for some years before germinating. At this distance of time I do not remember the number of years that had been known to elapse, but other crops, like Potatoes, were often got off the land at intervals before the Henbane crop was realised. We all know how some people still stick to the story of the Mummy Pea, but between the Pea, the Henbane and Mr. Charles Comfort's plants there is a wide range of years, so that some reasonable conclusion may yet be arrived at.—JOHN R. JACKSON, *Claremont, Lympstone, Devon*.

Too-much-alike Auriculas.—There is no doubt that many of the Auriculas are too much alike, and "Taplow" is justified in calling attention to the matter. Here is a fine chance for the National Auricula Society to follow the Sweet Pea Society, and classify the various forms and let the cult know which are really distinct. Catalogues and lists are often bewildering to amateurs, while the professional gardener would be saved a lot of time and trouble if he was told which were similar. Many are not up to show form, although they may be good garden plants; it does not always follow that show plants are the best for general purposes. The following twelve would be useful, and produce a varied display in due season: Argus, Bluebell, Duke of York, Firefly, Rosy Morn, Uranie, Teviotdale, Thetis, The Bride, Mrs. H. Turner, Dazzle and Miss

Ashton. In a list before me they are quoted at 1s. and 1s. 6d. each, and flowering samples are sent out. There are other good and distinct kinds, but the price is accordingly higher, and this will be readily understood when I say that some Auriculas are very shy in producing offsets. Among the selfs are Buttercup, Mikado, Ruby, Favourite, Mrs. Phillips and Lord of Lorne. These average about 2s. each. Of the green-edged, Mrs. Henwood is among the best. George Lightbody, raised over fifty years ago, is still unsurpassed in the grey-edged, but the constitution is weak, and the short-pursed novices would do well to choose the cheaper George Rudd or Olympus. In the white-edged section, Acme and Heather Bell are recommended. The edged kinds are more expensive, and vary from 2s. to 10s. 6d., but those quoted are near the former figure. Whenever possible, it is best to select the plants in flower, either in the nursery or at one of the Auricula shows.—T. W. B.

Snapdragons for Winter.—I was interested in the description and comments in the issue of May 2, page 220, on the winter-flowering Snapdragon (*Antirrhinum*) Nelrose. There it was given under the varietal name Melrose, but that was an error. The note refers to the perpetual-blooming character of Nelrose, and says that this type is largely employed in the United States of America. These references are correct. Just after the Chrysanthemums begin to wane early in December—for the Americans do not want them later—one begins to see charming little basketfuls of Snapdragon. These are favourites right on until the Daffodils appear in quantity in April. The raiser of *Antirrhinum* Nelrose was F. W. Fletcher, of the firm of F. W. Fletcher and Co., Auburndale, Massachusetts, who began operations over fifteen years ago. At that time the majus varieties had poor flowers, sparsely set on the spikes, and there was a need of bright, clear colours. The first crosses, he tells me, were made with the best varieties then existing, followed later by the named sorts of *Antirrhinum nanum grandiflorum*. These later crosses gave the material Mr. Fletcher had been looking for, and though they were a very mixed crew, it was only a matter of selection from thousands of seedlings to get a strain that began to approach to the ideal of what a commercial *Antirrhinum* should be, i.e., one that would flourish indoors in winter and produce plenty of attractive cut blooms. So it was out of these cross-bred seedlings that Nelrose came, and four years ago Messrs. Fletcher had a sufficient stock to yield them commercial cut flowers. The colour is a rich silvery pink, and the flowers and spikes are large and handsome. Nelrose is equally good as a bedding plant, growing about twelve inches high out of doors—in America, at least. Every growth makes a flowering spike, so that if the plant is kept growing it must flower, summer and winter. I am pleased to say that Mr. Fletcher is of English descent, and was born in Massachusetts fifty-six years ago. He works on Mendelian lines in his hybridising and cross-breeding. Formerly he was editor of the *New England Florist*, since merged with the *Florists' Exchange*.—J. HARRISON DICK, *New York*.

FORTHCOMING EVENTS.

June 16.—Royal Horticultural Society's and National Gladiolus Society's Combined Show.
June 17.—Yorkshire Gala (three days).

"THE GARDEN" PLANNING AND PLANTING COMPETITION.

For the benefit of new readers we are publishing on page vii. the coupon to be sent for the outline plans in connection with our competition for planning and planting the little garden. In this competition we are offering cash prizes to the total value of £33 12s., as well as a number of book prizes, for the best designs for planning and planting the little garden. Full particulars will be sent to anyone who writes to the Editor for them and encloses 1½d. in stamps to cover cost and postage. All envelopes relating to this competition should be marked "Planning Competition" in the top left-hand corner. Replies to the numerous questions that have been sent in by intending competitors will be answered in our next issue. We would remind readers that there is no time limit for entering the competition, but completed designs must be delivered not later than September 1 next. We take this opportunity of thanking those readers who have so kindly written letters of appreciation concerning the competition.

UNCOMMON FLOWERS AND FOLIAGE FOR VASES.

THERE is a strange dislike to umbelliferous flowers for vase decorations. Sentiment, perhaps. One sometimes sees the compact-headed Masterwort used, but the much prettier loose-headed sorts scarcely ever, if at all. Some of these are not only pretty, but they are faintly, and sometimes strongly, aromatically perfumed, and the foliage of kinds not particularly desirable for their flowers is not to be despised. Of the latter, mention may be made of Spiguel, the leaves of which are elegantly cut, fragrant and very dark green. Sweet Cicely, which flowers as early as March, along with nice white flowers has scented, Fern-like foliage, and is sometimes known by the name of Sweet Fern.

One of the very prettiest, and which can be cut in long sprays with foliage and flowers, is the common garden Chervil. This is a recommendable vase flower, either for mixing with other kinds or for using alone, and it can be had from spring to late autumn. The common Cow Parsley, which succeeds Sweet Cicely, is also a valuable asset for certain purposes, but only for its flowers, which are not fragrant. The common Fennel and the Giant Fennels, with their greenish yellow flower-heads and finely divided foliage, are very useful later in the year, and the humble Carrot, whether in flower, in seed, or with the reddened leaves of autumn, affords splendid material for the decorator. *Selinum* (*Oreocome*) *Candollei* is an exotic species that can be recommended for large arrangements.

The only use I know for Bishopweed, that most determined colonist and almost ineradicable weed, is as a cut flower. It is really very handsome, and well worth working up with other early autumn blooms. It is scarcely necessary to mention the Eryngiums, which form exceptions to the vast number of umbelliferous flowers by their delightful colouring. What I specially desire is to draw attention to a vast fund of decorative material to a large extent ignored and neglected.

R. P. BROTHERSTON.

THE NEWER CHINESE RHODODENDRONS.

AMONG the almost countless number of new plants introduced during recent years from Central and Western China, new species of *Rhododendron* are very prominent. The Himalayas have, since the travels of Sir William Hooker, been regarded as the headquarters of the genus; but the exploration of China by Dr. Henry, Mr. E. H. Wilson, Mr. G. Forrest, and the three French missionaries, Les Abbés David, Delavay and Farges, has abundantly proved that Central and Western China must in future be regarded as the *Rhododendron* headquarters. Mr. E. H. Wilson during his four journeys collected over seventy species and several varieties. A number of these have been known to botanists and named from dried specimens for some time, but many are entirely new introductions. Some of those which have already flowered with us are valuable additions, though the *Rhododendron* already holds pride of place as our best evergreen flowering shrub. It is worth recording that nearly all Mr. Wilson's *Rhododendrons* are evergreen, a notable exception being the true *R. sinense*, around which and *R. mollis* considerable difference of opinion exists as to their being synonymous or distinct species. The rich yellow-flowered *R. sinense* seems to support the contention of nurserymen that our present-day race of garden Azaleas are hybrids between the yellow *R. sinense* and *R. mollis*, the type of which has apparently variable rosy pink blossoms.

The Chinese *Rhododendrons* represent a remarkable diversity of growth, foliage and flowers. A few extremes worth noting are *R. intricatum* and *R. fastigiatum*, alpine species less than 18 inches high, with leaves half an inch in length. Contrast these with *R. auriculatum*, a large bush or tree 30 feet high, with leaves 3 inches to 5 inches wide, and sometimes exceeding a foot in length.

Unfortunately, some of the newer species flower as early as March and April, also starting into growth while we are troubled with spring frosts. This means that, if possible, positions should be selected to plant them where they will be shaded from the early morning sun, so that, in the event of frost, the foliage can thaw gradually before the bright rays of the sun reach it. The places where we shall see those not suitable for general cultivation will, no doubt, be in the sunny South and West in company with the Himalayan species and hybrids. There is another interesting side to the value of these newer introductions in addition to their individual value for garden decoration, and that is for hybridising. Fame awaits the raiser of a perfectly hardy large flowered evergreen

yellow or blue flowered *Rhododendron*. Among the new species we have at least three with yellow flowers, *R. ambiguum*, *R. lutescens* and *R. flavidum*, while there is a lot of blue in *R. intricatum* and *R. fastigiatum*. A few particulars respecting the best of those which have flowered may prove of interest to readers.

***Rhododendron ambiguum*.**—A bushy plant with obovate, dark green leaves. The yellow flowers appear during April in small, terminal trusses. This species has, unfortunately, been put into commerce as *R. concinnum*, a species with purple flowers.

***R. Augustinii*.**—This is a most beautiful species, with evergreen oblong-lanceolate leaves

It is in the way of the beautiful *R. yunnanense*, but flowers rather early. The French missionaries sent seeds of this species to M. Maurice de Vilmorin.

***R. concinnum*,** the true purple-flowered species, gives promise of being a useful evergreen, and as it flowers during May, the blooms develop under much more favourable conditions. The flowers are 1½ inches to 2 inches across, and prettily spotted with reddish purple.

R. fastigiatum is a dainty little alpine species reaching a foot or rather more in height. The small, evergreen leaves are half an inch long; flowers lavender purple. It is allied to *R. intricatum*, but flowers nearly a month later, and has protruding stamens. This was, I believe, the first of Mr.

G. Forrest's *Rhododendrons* to flower in this country, which it did in 1912, eighteen months from the time of sowing the seeds. A. O.

(To be continued.)

FLOWERING SPRAY OF RHODODENDRON CHARTOPHYLLUM, A NEW CHINESE SPECIES.

and mauve, lavender or white flowers. The bushy plants are very free flowering. The seedlings exhibit considerable variation in the colour and size of the flowers, the best only of which must be selected for propagation. It is evidently fairly common in China, having been collected by Dr. Henry, Mr. E. H. Wilson and the French missionaries.

R. adenopodum is an April-flowering species, with pale rose-coloured flowers 2½ inches to 3 inches in diameter, first introduced to France by Abbé Farges and later by Mr. Wilson.

R. chartophyllum is an evergreen bushy species with white to lavender spotted flowers.

finest possible spray, and care must be taken that both sides of the leaves are thoroughly covered. This gentleman recommends liver of sulphur for the wash at a strength of one ounce in five gallons of water on the opening leaves, and subsequently one ounce in four gallons as the foliage hardens. With me this solution by itself does not seem to adhere to the leaves properly. It is apt to run into large drops, and I have found it better to mix a moderate amount of soft soap with it, which will give it the desired effect. Dr. Hamilton draws a close analogy between the chief causes of infection of the human body by disease and of Roses by mildew. From his deductions we learn that a wound on the surface

ROSE-GROWING IN TOWN GARDENS.

THE TREATMENT OF MILDEW.

ALL who have attempted to grow Roses in confined areas are familiar with the appearance of mildew, and most people are aware that it is caused by a minute fungus which spreads over the surface of the leaves and sends its roots into the cells, extracting the sap and causing the leaf to wither. It is important to realise that this fungus becomes visible only when it is bearing countless spores and is thus in a fair way to infect the whole Rose garden, as the wind will quickly distribute these spores among the rest of the plants. It is therefore only by taking preventive measures before the disease has actually appeared that we can hope to combat it effectually.

In the "Rose Annual" for 1914 the best methods for dealing with mildew are discussed in a series of interesting papers contributed by eminent rosarians, and the subject is one of particular interest to town gardeners. The advice of all tends in the same direction. Spray early and often is the rule, and, as Mr. M. A. Bailey points out, it is important to use a good syringe or machine capable of throwing the

of leaf or stem forms a point of danger, that weakly or overcrowded plants are especially subject to disease, and that over-watering the roots by lowering the vitality of a plant enables the mildew to obtain a firmer hold. We are counselled to keep the plants as clean as possible, not to overcrowd them, to fork over the surface of the beds frequently and to avoid wounds or abrasions. As regards the latter, Dr. Hamilton suggests that the plants should not be fingered, advice which is difficult to follow where green fly is a real trouble and time is limited; but when these insects are removed by hand it is certainly imperative to do it carefully, so that the surface of the leaf is not broken.

The Rev. F. Page-Roberts has found Jeyes' Horticultural Wash, Calvert's Carbolic Soap and Berger's Lime-Sulphur Solution all effective, as well as dark-coloured flowers of sulphur blown over the plants while the dew is on them, specially made bellows being used for this purpose.

Dr. A. R. Waddell created considerable interest last year by recommending the spraying of the plants with a solution of formaldehyde in the proportion of one teaspoonful to a gallon of water. He again advocates this strongly in his present paper, and gives interesting details of the results obtained by this treatment. It would appear, however, that the remedy is apt to be dangerous, for Mr. Page-Roberts contends that it is liable to burn the young growth, while Mr. Darlington has found it ineffective in treating mildew on Roses under glass.

One fact emerges from the discussion. As Dr. Hamilton points out, there are many remedies but there is no cure. Spores are ever present, awaiting favourable conditions in which to germinate, and only regular spraying will prevent the appearance of mildew. Another point made by the same writer is the importance of selecting hardy varieties. Very few Roses are actually immune from attack, and anyone wishing to grow a representative collection will hardly care to limit his choice to these; but if a particular variety has been badly infested, the wisest course is to get rid of it and replace it with plants of another kind.

P. L. GODDARD.

RAISING HERBACEOUS PERENNIALS FROM SEEDS.

IN every department of gardening there is wisdom and a certain fascination in the raising of plants from seeds, and that these extend into the region of hardy plant growing none will gainsay. The wisdom lies in the obtaining of one's "pound of flesh," so to speak. It may be one hundred or five times that number of seeds for a shilling, and if only a fourth part of the first-named number vegetate and make good plants, the expenditure might still be considered good and economical. The fascinating side of the subject—it is full of interest and moment to even the most advanced horticulturists—is that one never quite knows what is coming. We know, of course, that we have purchased seeds of *Aubrietia*, *Gaillardia*, *Carnation* or *Delphinium*, and committed them to the earth in "sure and certain hope," though we cannot even guess what their "resurrection" will be. In other words, while there will be the usual array of ordinary seedlings, and some—the weeds—that might be regarded as extraordinary, there is also just the possibility—often the probability—of some others being extraordinarily good.

The Small Seedlings.—What is lost in the discarding of the small seedling plants no one ever knows, yet they are worthy of our closest attention. Frequently—I had almost said invariably—the small seedling plant, the slow grower at the start, is often of superior quality, and should be catered for accordingly. Yet too often these are discarded by the careless or thoughtless worker at the time of pricking off because they are less easy to handle. I once caught red-handed an assistant, who for days had been trusted with the pricking off of a fine strain of tuberous *Begonias*, throwing under the potting-bench a whole host of the smaller seedlings, the stronger growers, the second and third rate flowers, probably coming readier to his hand. A cursory examination of his past work revealed the fact that there were no very small seedlings pricked off; hence one could only guess at the loss. Naturally, the pricking off of the smallest seedlings constitutes the more tedious part of the work; but good things were ever wrapped up in small parcels, and it is in these tinier specks of vegetable life that the good things are usually found.

The Seed-Bed.—At this season of the year, seeing that the object of sowing now is to obtain large plants for flowering a year hence, the seed-bed should be formed in the open and in a partially shaded position. The plot of ground should be clean, well tilled, finely broken up and raked down as evenly as possible. Where light soils obtain, this will prove quite easy. Where the soil is heavy or of a more lumpy as well as stony nature, greater preparation will be required. In such a case a fine surface may be formed by raking off the stones, by the addition of finely sifted soil or even a little *Cocanut* fibre refuse. By the aid of a few boards and a spare frame-light a bed can be so

formed that birds and other animal life can be kept at bay. A thinly shaded frame-light or one darkened by mats, while performing the above-named function, conserves moisture, also hastens and ensures a more uniform vegetation of the seeds. These are important. Should the seeds be sown in a fixed frame, see to it that the surface of the seed-bed is quite flat and not at the same inclined angle as the frame, which runs all the water to the lowest point.

Sowing the Seeds.—The only rational way is that of sowing in drills, arranging these at 9 inches apart. By these means hoeing, thinning and weeding are easily performed, whereas, on the broadcast seed-sowing system, weeding is less easy and hoeing impracticable. The best way to form the drills is to provide an inch wide board and press it into the soil half an inch or so deep. In this way the drill and the straight line are forthcoming by one and the same process. For the covering, a little fine soil with *Cocanut* fibre will do quite well. Each variety or kind should be labelled as sown, and the whole gently watered when the work is completed. Thin sowing of the seeds is a point so often urged that it might appear superfluous to repeat it. Yet it is of the highest importance. The operator should remember, too, that large seeds may be safely buried an inch deep, while the smallest—those approximating to dust-like particles—will be better with little or no soil covering at all. Even *Polyanthus* seed, neither notoriously small and certainly not large, is best with little covering up, and, like others, is quite content with the shelter the interstices of the soil afford. Subjoined is a list of plants—by no means exhaustive—that may be sown at the present time, with hints as to soil and other matters which I hope may prove helpful to the general reader.

E. H. JENKINS.

SWEET PEA NOTES.

Here are Sweet Peas on tip-toe for a flight
With wings of gentle flush o'er delicate white,
And taper fingers catching at all things,
To bind them all about with tiny wings.

WITH joy we proclaim the arrival of the Queen of Annuals. As anticipated, the Chelsea Show produced some notable exhibits of Sweet Peas, of which a detailed account was given in

the Special Chelsea Show Number of THE GARDEN. The brilliant sunny weather and the quality of the blossoms made it difficult to remember that it was not the Holland House Show. Such fine displays of exquisite flowers should give a fillip to the culture of Sweet Peas under glass, and every Sweet Pea lover possessing a light, airy house will find they amply repay all the care bestowed upon them.

Sweet Peas Under Glass.—

Continue to give as much air as possible, and where a picking of flowers has been made, the plants will benefit by applications of liquid manure. As previously mentioned, start with weak soot-water, and, personally, I think this should form the principal liquid used, as it cannot do any harm. A plan I have found most beneficial is to give a good top-dressing (a fair sprinkling) of Dobbie's Sweet Pea Manure or Ichthemic Guano or Clay's Fertilizer, and then a mulching with spent Hops, watering with clear water, with occasional doses of weak soot-water. It is essential that the plants are not allowed to become dry, and the mulching materially prevents this, the Hops being clean and less unsightly than anything else. Whether the fertiliser be used or not, the mulching is absolutely necessary. If liquid manure be relied upon, I recommend that a watering of soot-water be followed after four or five days by an application of superphosphate at the rate of 2oz. to three gallons of water. The next watering of alternate clean and soot water might be followed by one of liquid manure made from cow-manure or farmyard manure, and should be well diluted. It is well to err on the side of over-dilution rather than risk the loss of plants through an extra strong mixture. "A little and often" is an absolutely satisfactory cultural maxim when giving liquid food. An occasional watering with phosphate of potash (half an ounce to a gallon of water) together with the foregoing will keep the plants in good condition for many weeks.

Disbudding.—All the side shoots must be kept rubbed out and no seed-pods allowed to form, and it is well to cut the blooms as soon as they

are fully out and commencing to show the seed-pods. By this means the strength of the plant is not wasted, and the succession of flowers is assured.

Outdoor Culture.—The weather conditions have been most uncongenial, and many growers are complaining of stunted growths and disappointed hopes. The stunted growths and the yellowing of the leaves are due to the very dry weather and bitterly cold nights we have recently experienced. Given moister conditions, they will quickly recover and make headway. Sandy,

All refractory shoots must be tied in, and where exhibition blooms are required, a thinning out may be necessary.

Thin Growths.—Vigorous growths in the majority of cases at present are conspicuous by their absence, and I have noticed that several growers have resorted to an early use of chemicals. This is really folly. In many instances the plants were impoverished through a prolonged stay in pots or boxes, and the drought has further checked them. The chemical is lying unused, and is therefore thus far wasted. A thorough watering, followed by frequent syringings, will be of more benefit than any manure. As I have so frequently stated, the chemical manures are most useful as an extra stimulant when the plants are in active growth, and I prefer to see the haulm strong and vigorous before an application of any concentrated fertiliser be made. If the drought continues, give frequent waterings, and try to create a sturdy growth by picking off all flower-buds that are prematurely forming.

Question of Scent.—I have read with considerable interest the letters that have recently appeared in the "Correspondence" columns of THE GARDEN bemoaning the loss of scent. Is it really so? Are we not under a delusion when we say a certain Sweet Pea has more scent than another? That some varieties are more fragrant than others we all agree, but an interesting experiment convinced me that our sense of smell is not to be depended upon entirely, any more than the sense of feeling. Probably most readers know that if one hand be placed in very hot water and the other in ice cold water, then both plunged together into lukewarm water, that one hand will declare the water hot and the other cold. A similar experiment was tried on a grower who most vehemently affirmed that the Spencer type lacked fragrance. He was blindfolded and a spray of Sunproof Crimson was given him. He said it was most fragrant. It was taken away and given him again, and this time he affirmed it had no perfume. Again and again the same flower was substituted for others, and after the first time it was declared to be lacking in

THE MOUNTAIN CLEMATIS, C. MONTANA, OVER A COTTAGE DOORWAY IN SURREY.

porous soils have specially shown dire results of the drought, and watering is absolutely essential. Where mulching with short, well-decayed manure or lawn mowings has been applied, the loss of moisture has not been so pronounced, and a constant use of the hoe in many instances has done much to mitigate the evils of the drought.

Tying.—Where growth is fairly rampant and vigorous, an almost daily survey is necessary.

Dorothy Eckford and Lady G. Hamilton were also similarly tested, and great was the surprise of the person, when his eyes were unbound, at the opinions he had given. Personally, I have tested the power of judging scent in other flowers by the same experiment, and my conclusion is that the sense of smell is not sufficiently reliable to notice accurately the difference in degrees of fragrance. It is quite possible for many varieties to have been raised from parent flowers with little

fragrance, as many raisers have striven for colour and form only, and it would be a great loss if the new Sweet Peas lacked the well-known and approved fragrance; but, on the other hand, it is unfair and unwise to condemn all Spencer Sweet Peas as odourless. S. M. CROW.

THE MOUNTAIN CLEMATIS.

CONSIDERING the ease with which *Clematis montana* will grow in almost any part of the country, one might almost imagine it to be a native of Britain, instead of which it was introduced from Nepal in 1831. Our illustration shows this *Clematis* effectively growing over a cottage porchway in the village of Clandon in Surrey, in which neighbourhood *Clematis montana* may be seen growing over balconies, walls, and even barns, flowering with great freedom. It is also to be seen rambling at will over Pine trees, the light star-like flowers being shown up to great advantage against the dark background of coniferous trees. It is indeed a beautiful subject and of very easy culture. *Clematis montana* does best in a hot sunny position, a south wall for preference, although it is often recommended for a north wall. If given a sunny position the wood is well ripened and the chance of a fine display of flowers the following year is greatly enhanced. Pruning ought to be done soon after flowering, when the weak growth should be cut clean away. This beautiful climber is not in the least fastidious about soil, but it appreciates one of a light nature and a plentiful addition of lime.

A WALL GARDEN IN DEVON.

IN case any of your readers are interested in wall gardening, I am sending you a photograph of a dry wall we have made here. It forms the retaining wall to the lawn, and is 180 feet long and faces due south. The first half of it was built in the autumn of 1911, and the second half, which is shown in the photograph, in September, 1912. The stone is from a local quarry, and was used exactly as it was quarried. The soil used for filling at the back was good garden loam, with bone-meal mixed with it. Most of the plants were put in the wall when it was being made, but many small ones have since been added. From the first the plants have all thriven in a remarkable way, and we have no trouble in the wall during wet winters with any of the *Dianthi*, *Asperula suberosa*, *Acantholimon venustum*, *Androsace lanuginosa*, *A. pyrenaica*, *Potentilla nitida* and *Wahlenbergia Pumilio*.

Among the many other things doing well may be mentioned *Aquilegia cærulea*, *A. Stuartii*, *A. glandulosa*, *Anemone sylvestris grandiflora*, *Iris pumila atrocærulea*, *I. azurea*, *I. cærulea*, *I. lutea*, *I. cristata*, *Zauschneria californica* (which

flowers regularly), *Symphyandra pendula*, *Statice minuta*, *Silene Elizabethæ*, *Saxifraga pyramidalis*, *S. longifolia*, *S. Salomonii*, *S. lantoscana lingulata*, *S. burseriana Gloria*, *Rosmarinus prostrata*, *Plumbago Larpentæ*, *Onosma alba rosea*, *Oenothera brachycarpa*, *Æ. ovata*, *Æ. W. Cuthbertson*, *Æ. Youngii*, *Mazus repens*, *Lithospermum Froebellii*, *L. prostratum*, *L. Heavenly Blue*, *L. rosmarinifolium*, *L. Zollinsieri*, *Hieracium villosum*, *Globularia nana*, *Dianthus alpinus*, *D. neglectus*, *D. cæsius*, *D. arvernense*, *Cytisus Ardoinei*, *Corydalis Wilsonii*, *Convolvulus Cneorum*, *C. althæoides*, *C. mauritanicus*, *Campanula Stevenii*, *C. turbinata*, *C. garganica hirsuta* and *C. Miss Willmott*, besides all the larger kinds of wall plants, including *Aubrietia H. Marshall*, *A. Lloyd Edwards*, *A. Fire King*, *A. Dr. Mules*, *A. Lavender*, *Helianthemum Fireball*, *H. venustum*, *H. Beauty* and *H. Rhodanthe carneum*.

AN INTERESTING WALL GARDEN IN DEVONSHIRE.

At the foot of the wall are many kinds of bulbs, including Tulip species, *Habranthus pratensis*, *Tritonia crocata*, *Sparaxis Tollens*, *S. Fire King*, *S. Constance*, *S. sulphurea*, *S. Judith* and *Ixia Fire King*. *Watsonia Ardernei* (which flowers splendidly and has not been lifted or covered for three years), *Iris juncea*, *I. filifolia*, *Anemone nemerosa Blue Bonnet* and *A. Allenii* do well in the partial shade of other plants.

This short list does not give one quarter of the plants growing in the wall, but it is enough to show that many of the plants that are doubtful in this erratic climate are very happy in a dry wall, where their roots are always cool and in perfect drainage, and their heads in every bit of sun that we may be lucky enough to get.

E. A. FROUDE.

Collapit Creek, Kingsbridge, South Devon.

TULIP AFTERMATH.

TULIPA SPRENGERI is in full bloom, which is only another way of saying that the curtain has been rung down and that the end of Tulip-time has come. This seems to be a convenient season to write about one or two matters of interest in connection with this flower.

Rise in Prices.—It will be news to many to be told that during the month of May there has been a miniature mania in Holland over late Tulips, more especially the deep rich purple and the brownish yellow shades. The *Gladiolus gamble* of last year seems to have whetted the Dutchmen's appetite for speculative dealings, and now, when it is believed, and I may say I think with good reason (see an article by Mrs. Francis King in

the *Garden Magazine* of New York for May, 1914, an extract from which is given at the end of this article), that America is waking up to the immense possibilities of Tulips, they are at it again. Old Haarlem must rub her eyes when she hears the doings of the Monday meetings in the Bulb Market, and wonder if the famous times of 1635 and 1636 and 1637 are about to be repeated. I am afraid we shall feel the result in increased prices in many of the very best varieties. The most startling rise is in that beautiful blue purple, The Bishop. Mr. Bourne's price in 1913 was 5s. per dozen; in his preliminary list for 1914, which I picked up at Chelsea, it is put down at 30s. Louis XIV., Viking, Jubilee, Frans Hals and such as Dom Pedro, Ronald Gunn, Mrs. Kerrell and Norham Beauty have all appreciated in value. Nor have Gondvink, Clio, Golden Bronze, Quaintness, Goldmine or Coridion (all brownish yellows) fallen.

There is one compensation, however. The flood gates that held back Clara Butt have at last been opened, and this once expensive gem is now a possibility for the man of moderate means.

Tulip Pluriflores.—Messrs. James Carter and Co. distributed the only one of this new French race which is in commerce last autumn—Mons. S. Mottet. I am wondering what their customers thought of it. I have had a fine bed in my own garden from *home-grown bulbs*. There was plenty of branching, four and five flowers on a stem being common, with two as a minimum and seven as a maximum. Then, the petals are adhesive. As the only hundred year old parishioner that I have ever had said to me in his one hundred and first year: "I aint given to dying," so the flowers of Mons. S. Mottet say: "We aint given to falling." *Last*, they certainly do. This gives them ample time to appear in a new dress, for they are none of your lightning change artists, but require a considerable time to put off their white and don their pretty rose costume. These branching Tulips *must* be "well done to," or they will not branch. If in any year they do not do so, then, immediately this failing is seen, feed them. Again, only the large-sized bulbs will branch. These are the two secrets of success, without which failure is certain. One must have a nursery bed in which to grow them on and feed them. With this adjunct all difficulties vanish. They are worth it; a large bed is a pleasing sight and a *very* uncommon one.

Early Flowering Novelties in Pots.

I believe I have found the very best pure white in commerce, if not in existence—White Beauty. It is a sport from that grand variety, Pink Beauty. To show how much alike the two are in habit and shape of flower, my gardener, without knowing its true history, "spotted" its origin. Those who know Pink Beauty will need no further recommendation beyond my saying "It is a chip of the old block." Another superb novelty is the glorious reddish orange De Wet. I am told it is a sport from that best of all Tulips, Prince of Austria. In this case, too, the chip is fully as good as the old block. I have grown De Wet in pots and also in the open, and in both circumstances it has proved itself highly satisfactory. I have to thank my good friend Mrs. Polman Mooy of Haarlem for many things, for making me Govda syrup-wafers for one thing, but for none more than for being the unintentional reintroducer of De Wet. She took her husband and myself to a Woman's Work Exhibition at Amsterdam last year, and there, decorating a prettily furnished sitting-room, were vases galore, of this, both to the "Heer" and myself, unknown flower. It looks so different to what it did at the Jubilee Exhibition that, although we had stood together before it there, neither of us recognised it now. The fact is, it changes with age. Whereas in early life the orange tone predominates, in later life it is the red. Visitors, one and all, to my garden have asked: "Where *can* I get it?" I really do not know who lists it, but as I am told the wholesale vendors, Messrs. M. van Waveren and Sons of Hillegom, are

sold out for this season, somebody must. It is the most notable "early flowering" introduction of recent years. A third novelty, which is also a sport, coming as it does from Cottage Maid, is Jeanette. It is unlike any other early Tulip in colour, being a sort of rich cerise crimson, edged deep pink. It is a long flower and the edges of the petals are a little laciniated. I am in two minds about it. I like its colour very much, but somehow there is something about its general look that I do not care for; but I am going to try it again; it is such a decided novelty. It has one recommendation—it is quite cheap compared with De Wet—hence I advise a trial.

Extract from "Notes Among the Flowers of May," by Mrs. Francis King: "Let me suggest

REGELIO-CYCLUS IRIS 'MARS.' THIS IS ONE OF A BEAUTIFUL NEW RACE DESCRIBED ON THIS PAGE.

to those who do not yet know the newer Darwins, Cottage Tulips, Breeders and Rembrandts an investment in a few bulbs next fall, if only a half dozen of each of some of the finer varieties, and see each for himself the wonders of these flowers. In the first three classes, if I were to choose four out of each as introductory lists, they should be these: Cottage or May-flowering Tulips—*Retroflexa superba*, Moonlight, The Fawn, Inglescombe Pink. Darwins—Clara Butt, Rev. H. Ewbank, Gudin and Euphrosyne. Breeders—Coridion, Golden Bronze and Louis XIV. . . . Would that I might have named Zomerschoon in the Cottage group—Zomerschoon, that too costly Tulip of unforgettable beauty." J. J.

REGELIO-CYCLUS IRISES.

THERE is often a certain negative similarity between the result of going to an auction sale of the contents of some well-known house and a large flower show such as Chelsea, or even the usual fortnightly shows of the Royal Horticultural Society. In the first case we find ourselves landed with what we do not want, and in the second with what we cannot grow. Surely few can say, "It has never been so with me." Maybe the Oncocyclus and Regelia

Irises have been the snare. For example, *susiana*, one of the best known, is not infrequently exhibited in London. It always has a certain strange fascination for me, but I seem to have a stronger will at shows than I do at sales, and so far neither *susiana*, nor *Gatesii*, nor *Lortetii*, nor *Korolkowii* has induced me to buy. I am told, however, that there is a sort of halfway house between the easy "Germans" and the impossible "Cushions," namely, a certain weirdly named strain raised by the great hybridising firm of C. G. van Tubergen of Haarlem and named *Regelio-cyclus* Iris. These (and the statement has the *imprimatur* of Dykes—"Iris," in "Present-day Gardening," page 28) are at least possibles if treated as advised by the aforesaid firm. I believe, to do them well, cold-frame culture, with the plants in the soil, is by far the best way to manage them. The difficulty is to prevent autumn growth, and to keep any that may come from the vicissitudes of winter and early spring. I saw the beautiful series of hybrids at the Royal Horticultural Society's show on May 5, and since then I have had a boxful of their charming refined flowers sent from Haarlem. They had been gathered in the bud, then stretched and tied to a rack of comfort, so that they reached me just opening, and a few hours in water gave me the pleasure of seeing for the first time in my own house living specimens of some of the best of this fairly amenable race. I should say that Mr. Thomas Hoog (nephew of the respected head of the firm, Mr. C. G. van Tubergen, jun.) had told me that if I followed his directions, he did not see why I should not succeed. That box did it. I am going to make the attempt to grow a few of them next season, and I have picked out three from those

sent which are quite distinct from one another and which are (each one) very beautiful. *Hecate* (a study in brown and grey), *Mars* (a blue-blooded beauty) and *Psyche* (a sort of combination of the two, with bluish standards and brownish falls) are the ones I hope to start with, and the first two are among the cheaper ones. A fourth, which is distinct, being of a sort of pale wine red colour, is *Hera*. I hope to include this too; and to make up half a dozen I am making a plunge from the descriptions in the catalogue, and am going for *Irene*, "a very chaste flower of a silvery white with chocolate brown veins," and *Medusa*, "deep violet, veined on a violet blue ground." JOSEPH JACOB.

GARDENING FOR BEGINNERS.

CUCUMBERS AND TOMATOES IN FRAMES: A USE FOR THE COLD FRAME IN THE SUMMER.

WHILE during winter and spring the cold frames are taxed to the utmost of their holding capacity, in the summer as a rule they are very little used. Among the numerous purposes for which the cold frame is adapted in the summer is the cultivation of Cucumbers and Tomatoes. These are welcome in most houses, and, as with most other home-grown produce, are doubly so when freshly cut from one's own garden.

The Frame Cucumber.—Though comparatively few amateur gardeners attempt the cultivation of Cucumber plants, they are really very easy to grow. To provide heat in the frame during the early stages of the growth of the plants, a hot-bed of manure and leaves should be made up. For a two-light frame not less than two loads of fresh straw manure and one load of leaves will be required. Get this together a fortnight in advance, mix it up thoroughly several times, watering if dry. Make up the bed 18 inches wider and longer than the frame, and about two feet deep. Tread firmly, stand the frame in position on the bed, and place in the middle of each light a mound of nice fibrous loamy soil. As fermentation of the manure proceeds, there will be a certain amount of steam in the frame, which must be allowed to escape by leaving a crack for ventilation. In from a week to ten days the frame will be ready for the Cucumber plants. It is as well to raise these in the greenhouse, sowing the seeds in pots about a month before it is proposed to plant them in the frame. This may be done at any convenient time from April to the end of June. Sow two seeds in a 3½-inch pot. If

both germinate, pull out the weaker one. When growing freely, move into 6-inch pots, so that good, sturdy plants will be available when the frame is ready. Would-be growers of Cucumbers who have no greenhouse should plant the seeds straight in the soil of the frame. The plants will grow quite as well, the only difference being that they will be a month later. Two plants are sufficient in each light of an ordinary frame. Three are shown in the illustration, one extra being put in in case of loss. Should all thrive well, it is far easier to pull one out than to put another in. Cucumber plants revel in a moist heat. In the morning and afternoon syringe with tepid water, unless a cold, wet period is experienced, when once a day will be ample. This will keep the soil fairly moist, but probably the roots will require an additional watering about once a week. Shade the plants from hot sun, damping down, syringing and closing

CUCUMBERS IN A COLD FRAME. IF ALL GROW WELL ONE WILL BE REMOVED LATER.

Rochford's Market, and Cluster (a free-fruited small variety).

Tomatoes.—During favourable summers Tomatoes produce a good crop of fruits outside, particularly when planted against a sunny south wall or fence. To supplement these a few plants should be cultivated in frames, as illustrated. Grown under glass in this way, the fruits ripen a month earlier, and as a rule the crop is heavier and of better quality. This is especially pronounced when there is not an excessive amount of warm, sunny weather during July and August to help the outdoor plants. A two-light frame will take six plants, three in each light. Plant these at the bottom 1 foot to 15 inches apart, with the growths leaning to the top of the frame. If the slope of the frame is not fairly steep, it should be raised a foot at the back by placing bricks under the woodwork on the ground. Air admitted here will do no harm; in fact, if anything it will be beneficial. Strain stout string or wire on hooks from the top to the bottom of the frame, one strand for each plant, as illustrated. Restrict each plant to a single stem, removing all side shoots, and regularly tie the leader to the string, or the top will be constantly touching the glass. Grow the plants entirely without shading the lights. Nothing is more liable to prevent the free setting of the flowers than heavy shading. Mulch the plants when growth is proceeding satisfactorily, and attend regularly to watering. Useful sorts to cultivate in frames are Early Market, Holmes' Supreme, Sunrise and Duke of York.

In the illustration it will be noticed that there are also Lettuces growing in the frame with the Tomatoes. A crop such as this can be very well grown in the frame while the Tomatoes are small, but they must, of course, be removed before the latter get so large as to obscure the light.

TOMATOES PLANTED IN A COLD FRAME, WITH YOUNG LETTUCES GROWING UNDERNEATH.

up about the middle of the afternoon to shut in some of the sun-heat. As soon as the young plants have made four or five leaves, take out the growing tips to encourage branching shoots. Spread these evenly over the ground, stopping again at intervals as growth proceeds. From time to time it will be necessary to remove some of the older leaves, and probably shoots also, as crowded plants are by no means the most fruitful, but rather the opposite. Regarding good sorts to grow in a frame, choice may be made from Reliance (the one illustrated, which fruits very early), Telegraph,

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Strawberries.—Now that Strawberry forcing is over, it is necessary to make preparation for next season's crop, and, assuming that a plantation was made in the autumn with a view to supplying early runners, there should be no difficulty now in finding sufficient for the early batch of plants, and these ought to be inserted in small, clean pots with as little delay as possible. Good rich loam should be used, and the pots may be half plunged in the soil between the rows of plants in order to reduce the need of frequent watering.

Melons in Frames.—These should now be making rapid progress and ought to be kept well thinned. Remove worthless growth from plants which are setting their fruits, and attend to the pollination of these every morning as soon as flowers and foliage are dry. As soon as a full crop has been secured, the shoots may be stopped at the first or second joint beyond the fruit, according to the space available, and a good soaking of clear water given. When the fruits are swelling freely, they may be placed on small inverted pots in order to expose them to the light, and also as a protection from insects. Syringe the plants freely on fine mornings, but avoid damping the foliage on dull days. A stagnant atmosphere must always be avoided. As the season advances and fruits are swelling freely, the plants should be assisted by liquid manure in some form, which must be kept quite clear of the stems. Further plantations ought to be made and seeds sown for succession.

Plants Under Glass.

Zonal Pelargoniums.—Plants which are intended for flowering in autumn and winter should now be ready for potting into 6-inch pots. Place them in a cool pit quite near the glass, and when they have become established they must be freely ventilated, and afterwards removed to the open and placed on a bed of ashes. Pinch the strongest shoots as it becomes necessary to keep the plants in shape. The most suitable soil for this purpose is good rich loam with a sprinkling of old lime rubble. A few crushed bones may be placed over the crocks with advantage.

Heliotrope.—This is a useful plant for the conservatory during the autumn, and for this purpose young plants which were rooted in the autumn or spring may be potted and grown on in a cool, well-ventilated pit. Pinch the strongest shoots to keep the plants in shape. The soil may consist of two-thirds turfy loam and one-third leaf-soil, which should be made moderately firm.

Tuberous Begonias.—These plants will now be making rapid progress in their flowering pots, and must be carefully staked in order to secure the maximum amount of light among the shoots. Seedling plants in pots should be potted on as soon as ready, so that the best may be selected for pot culture next season.

Chrysanthemums.—The final potting should be accomplished with as little delay as possible. Stand the plants in some open quarter in order to prevent them from becoming drawn. As soon as the pots are well filled with roots, some stimulant should be applied several times weekly.

Fuchsias for autumn flowering may be grown in any cool structure. Water freely with liquid manure as soon as the plants are established, and pinch side shoots as it becomes necessary to keep them in shape.

The Flower Garden.

Summer-Flowering Chrysanthemums.—These are growing freely, and should be carefully staked before growth is too far advanced. Thin the shoots to five or six on each plant, and stake separately, allowing sufficient space between them to admit plenty of light and air. Water freely during dry weather, and hoe the soil between the plants at frequent intervals.

Summer Bedding.—To encourage free growth among plants which have recently been bedded out, the syringe should be used each evening and the beds watered at frequent intervals. Stake

the plants as early as possible, and, as many of them will require pegging down to the ground, this should also be accomplished as soon as possible. Verbenas, Petunias and Ivy-leaved Pelargoniums are among the first to require attention.

Planting Dahlias.—There must be no delay in planting and staking Dahlias in the case of spring-struck plants with single stems. A careful watch should be kept for slugs, which will soon destroy young plants. Every effort ought to be made to complete the planting of all tender subjects as quickly as possible, so that they may not become stunted before they are put out.

The Kitchen Garden.

Mushrooms.—Beds may now be made up behind a north wall or in a shed facing east for the supply of Mushrooms during September and October. Let the material be well prepared and trodden tightly together to the depth of 2 feet, in order to retain the heat as long as possible after spawning, which should take place when the temperature of the bed is as near 80° as possible. After a few days, when the heat is inclined to drop, a covering of long litter may be placed over the surface to prevent evaporation.

Runner Beans.—A second sowing may be made now in order to keep up a supply as far into the autumn as possible. Stake the plants as soon as sufficiently advanced, and give a liberal supply of water during the summer months.

Lettuce.—Make frequent small sowings of Lettuce seed, and transplant some of the seedlings as soon as large enough. By this means a continual supply may be available through the summer. A cool situation should be chosen for the next few sowings, and if the soil is of a heavy nature, so much the better. If dry weather prevails, frequent waterings will be necessary. Small sowings of Endive may also be made and treated in the same way as Lettuce.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cauliflowers.—Make another small sowing of these to keep up a succession to those sown in March. To many this might be thought to be much too late, yet it is astonishing what useful heads can be had from this sowing. As it is necessary to keep up the supply, sow Early London, Walcheren and a little seed of Autumn Giant. In consequence of the extremely cold weather experienced in many places in May, a good many of those planted earlier may have buttoned. Go over the plot and make up the blanks from the seed-bed.

Leeks.—The most forward plants will now be ready for planting, and as these are gross feeders and cannot very well be fed from the surface, it is essential that the ground be well manured before planting. Rake the ground quite fine and make holes 9 inches apart and 15 inches between the rows. Many growers cut off the tops of the leaves before planting, averring that it greatly strengthens the roots; but for ordinary purposes it seems to me to be immaterial whether they are cut or not.

Cucumbers.—Now that most of the frames will be empty, a few plants may be put in as advised some weeks ago. After planting, keep the frames fairly close for a time, and throw a mat over them during the hottest part of the day. By all means guard against cold winds and draughts, and supply abundance of moisture during the earlier stages of growth.

The Flower Garden.

Roses.—Among the various sections of Roses, perhaps the present time will be the most interesting and possibly the most anxious. The Tea-scented varieties growing against walls will, in many cases, have suffered rather severely from the attacks by aphids during the unusually cold spell in May. At that season the foliage is more susceptible to injury than at any period of their growth. When the foliage appears curled, there is no doubt that the maggot has got a footing, and hand picking will be out of the question.

Syringe the bushes with Quassia Extract or other approved insecticide to prevent it spreading, and, being against a wall, it is more than likely they will require moisture at the roots. Among Roses of recent introduction, which, in the majority of cases, are rather weak, it will be advisable to pinch out the earliest flower-buds, which will have the effect of throwing vigour into the plant.

Spring-Flowering Plants.—Those plants that were used for spring bedding, such as single and double Arabis, Polyanthus, Aubrietias and Daisies, must be attended to at once, as very frequently they have to be moved to make room for the summer occupants before they have completed their growth. They should be divided and planted in nursery lines to make stock for next season's supply, and, should the weather be dry, an occasional watering will be necessary. Such plants as Myosotis and Alyssum saxatile are best grown from seed, and may be sown now.

Herbaceous Plants.—These will now require constant attention in the way of staking and tying, and some of the most delicate sorts, such as Ostrowskia, Scabiosa caucasica and many others that are subject to attacks from slugs, should have the soil stirred round them and be given a dusting of soot. See that the stronger-growing sorts are not allowed to encroach on the weaker-growing plants; each plant should stand out distinctly.

Plants Under Glass.

Stove and Greenhouse Climbers.—Most of these are growing luxuriantly and must, to a certain extent, be held in check. In thinning and tying and otherwise regulating the long growths, regard must be had to the particular plant in hand; weakly shoots should be removed and larger ones looped up in the most natural manner possible. Cuttings can be taken of Hibiscus. I find they root readily, and if pinched and allowed to remain in comparatively small pots, they soon show flowers. These will be found to be extremely effective arranged among Ferns.

Bouvardias.—The young plants that were potted some weeks ago will now be ready for a further shift into a size larger pot. Now that the weather is getting warmer, they may be moved into a frame, and for a time they should be slightly shaded during the hottest part of the day. Give them a slight spraying with the syringe twice daily, and as they advance in growth they will be greatly benefited by occasional waterings with weak liquid manure. Any shoots getting away from the others should be pinched to promote a compact habit.

The Hardy Fruit Garden.

Apples and Pears.—Trees growing on walls should now be gone over and have the shoots stopped. This must be done carefully, as, if all the shoots were pinched indiscriminately, the result would be that the strongest would again break into growth and produce a lot of small, useless wood. These vigorous shoots should be left somewhat longer than the weak ones, and can be finally shortened back at the winter pruning. Remove all badly placed and ill-shaped fruits, and leave no more on the tree than it is capable of bearing. I see caterpillars are becoming very troublesome, possibly owing to the recent cold weather. Means should be taken to prevent them spreading by vigorously syringing with Quassia Extract or some other approved insecticide.

Fruits Under Glass.

Vines.—Young pot Vines for next year's fruiting will now be growing rapidly and may be assisted with liquid manure or a little of Thomson's Vine Manure. They must be kept free from spider, as any damage to the foliage from insects or otherwise will most certainly have an injurious effect on the proper ripening of the canes. The laterals should be closely pinched, and the leader stopped when the desired length has been attained.

Figs.—The second crop will now be showing nicely on the earliest trees, and the fruit should be thinned out judiciously. Pinch the young growths as they advance, say, at the fifth leaf, unless, of course, an extension is wanted. Those growing in pots will require to be carefully attended to, as, if allowed to become dry, they receive a serious check.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Iris Iota.—An interesting and beautiful hybrid, having for its parents the Californian *I. Purdyi* and *I. tenax* from North-Western America. The new-comer partakes more of the first-named species, the creamy or whitish ground being freely reticulated with lilac and rose. From Mr. Rickarton Dykes, Godalming.

Iris Chrysographes.—This beautiful and graceful kind was shown by Miss Willmott and Mr. Dykes. It is probably allied to the *I. sibirica* set, and has the same narrow grassy leafage. The dominating colour tone is intense violet and imperial purple, the long, ovate-acuminate blade of the falls exceedingly rich in colour.

Erigeron hybridus B. Ladhams. The pot-grown plants were 2½ feet high, the predominating colour tone of the flower-heads rosy pink, quite a new shade in this family. From Mr. Ladhams, Southampton.

Lupinus Primrose Dame.—A charming variety, having deep canary-coloured flowers in long spikes. In general appearance it is a glorified Tree Lupine, the greatly extended raceme of flowers suggesting the influence of *L. polyphyllus*. Really, the flower-spike is that of the latter, the habit that of the Tree Lupine. A valuable plant. From Messrs. Barr and Sons, Covent Garden.

Papaver Lady Frederick Moore. A very handsome Oriental Poppy. The pink colour is very charming. From Mr. Amos Perry, Enfield.

Clematis Sieboldii.—Of this very old and beautiful species a well-flowered example on balloon trellis was shown by Miss Willmott, Warley Place. The petals are rounded and white, which contrasts well with the spreading cluster of floral leaves at the centre of the flower.

Verbascum Warley Rose.—A 5-feet-high specimen of this was shown in a tub. It is invaluable by reason of its colour, which is of rose pink shade and quite new in this fine race of plants. The branching raceme is much more graceful than the close spikes of older varieties. Given freedom, this must become a great garden plant. At present it is unique. From Miss Willmott, Warley Place.

Deutzia discolor elegantissima.—A very beautiful shrubby kind with a profusion of pink-flowered trusses in axillary clusters on long, arching, graceful branches. The starry flowers add a charm to a delightful plant.

Ribes Brocklebankii.—Valuable for the uniform greenish golden colour of its leaves, and likely to be of service for grouping in conjunction with others of more sombre tone. These came from Elizabeth Lady Lawrence, Dorking (gardener, Mr. W. Bain).

Mimulus Wargrave Fireflame.—A dwarf-growing kind with large flowers of brownish scarlet hue, very freely produced. The plant

is about eight inches high and very striking. Shown by Messrs. John Waterer, Sons and Crisp, Limited, Bagshot and Twyford.

Iris lævigata alba.—This is the white-flowered form of the typical species, and a beautiful and rare plant.

Iris sibirica Emperor.—As far removed by its superiority from *I. s. orientalis* as that fine variety is from the typical species, than which we do not think we can better describe it. In colour it is deeper and richer. A good plant in every way.

Iris Kashmir White.—Best described as a giant pallida form, with handsome white flowers on 4-feet-high stems. The lateral branches are unusually long, which gives the plant an import-

RIBES BROCKLEBANKII, A NEW HARDY SHRUB WITH BEAUTIFUL GOLDEN FOLIAGE.

ance of its own. These three widely distinct and good garden Irises came from Messrs. R. W. Wallace and Co., Colchester.

Carnation Mrs. Griffith Jones.—A superbly formed flower of soft apricot colouring. A very charming variety.

Carnation Mrs. Brotherstone.—A freckled or fancy sort, in which the predominating shades are purplish and crimson. The flower is very large, of superb form and strongly Clove scented.

Carnation Robert Bruce.—Deep apricot, with almost orange shading, which adds intensity to an exceptionally rich bit of colour. A very fine self. These three fine novelties were shown [by Mr. James Douglas, Great Bookham, Surrey.

AWARDS TO STRAIN.

Lupines.—Hybrids of arboreus and polyphyllus, embracing yellows, rose and yellow, violet, blue and white, lavender and dark blue. From Messrs. Barr and Sons.

Aquilegias.—A particularly high-class lot in which scarlet and yellow, cream, white, pink and other shades combined. From Mrs. Scott-Elliott, Teviot Lodge, Hawick, N.B.

Antirrhinums.—A remarkable range of colours in the three degrees of heights, viz., Tom Thumb, Medium and Tall, was displayed, the flowers and spikes being of exceptional size. For fuller details see report of the show. From Messrs. Dobbie and Co., Edinburgh.

All the foregoing were shown before the floral committee of the Royal Horticultural Society on the 3rd inst., when the awards were made.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

ANTIRRHINUMS DISEASED (E. K. P.).—The Antirrhinums are attacked by the fungus *Septoria Antirrhini*. This fungus is apparently spreading over the country, and we have had several complaints lately of the damage it has caused. Remove the diseased portions as completely as possible, and spray the remainder with potassium sulphide at the rate of 1oz. to three gallons of water.

"FIRE" IN TULIPS (W. W.).—The Tulips are suffering from "fire," due to the attack of the fungus *Sclerotinia parasitica*. You will see that we have given an account of the method of dealing with this to several of our correspondents lately in our columns, and think it would be as well to destroy the bulbs of Golden Crown and remove the soil as completely as possible, so as to avoid harbouring the resting bodies of the fungus for another year, replacing it with fresh soil.

TREATING A SLOPE (The Birches).—The terraced arrangement would, we think, prove rather formal, and two other ways remain if not incongruous with the surroundings. These are leveling up the bank and constructing a retaining wall at the front, specially arranged to receive a fine vegetation, which would also permit of bedding plants on the flat area above, or it may be done down in grass. The other way would be to construct a small rockery on the slope. Either of these would add permanent interest to the surroundings and do away with your present difficulty. The better time for the above work would be early autumn. If you think we can further assist you, please write us again.

TULIPS DISEASED (J. F. B.).—The Tulips are affected by the fungus *Sclerotinia parasitica*, to which we have frequently referred of late. The fungus is apt to form resting bodies in the soil and to attack Tulips planted therein in succeeding years. It also forms resting bodies just in the necks of the Tulip bulbs, and so may be carried over from year to year. The disease is always most prevalent when the foliage is exposed during its growing period either to cold winds or frosts, and it repays the attention for shields of Broom or other shrubs to be put among the growing plants.

TREES AND SHRUBS.

ABOUT LONICERAS (Mrs. R.).—Of the *Lonicera* concerning which you enquire, *Lonicera nitida*, of comparatively recent introduction from China, is a neat, twiggly evergreen shrub, clothed with small, ovate, glossy leaves of a leathery character. The flowers are creamy white and fragrant, but not large enough to be very conspicuous. *Lonicera xylosteum* reaches a height of 5 feet to 6 feet and more. The flowers are small and cream coloured, and altogether it is not of high ornamental value. The third, *L. tartarica splendens*, will at times considerably exceed the height of 6 feet, but may be kept down to

that if required. The flowers, which are borne in April and May, are reddish in colour. *Lonicera nitida* may be associated with choice shrubs, but the other two are only fit for the wilder shrubbery. They are of a very accommodating nature, perfectly hardy, and will grow in any ordinary soil.

MISCELLANEOUS.

CRAB APPLE LEAVES (*Mrs. M.*).—The leaves of the Apple sent are apparently suffering from cold draughts, and the brown spots may prove a centre from which fungus attacks may spread. It would be well to spray the trees with half-strength Bordeaux mixture in order to check the trouble.

NAMES OF PLANTS.—*W. J. S.*—We believe the Rose to be *Mme. Jules Siegfried*, if it is a climber; if a dwarf grower, it may be *Zephyr*.—*E. M. Whittlesey*.—Rose Captain Caristy; if a strong grower it would be the climbing form of this old Rose.—*Ignoramus*.—Rose General Schablikine.—*Subscriber*.—Sedum roseum, Rose-root or Cudde-me-tight.—*E. B. Astrop*.—1, *Achillea Huteri*; 2, *Achillea rupestris*; 3, *Sedum aizoon* variety.—*M. E. R.*—*Syringa persica*.—*A. W. F.*—*Geranium sylvaticum*.—*W. D.*—1, *Cotoneaster horizontalis*; 2, *Olearia Haasti*; 3, *Arbutus Unedo* (Strawberry Tree); 4, *Buxus sempervirens* (common Box); 5, *Spiraea van Houttei*; 6, *Crataegus Pyracantha*.—*C. P. Kinson*.—The Lilac sent was one of the many unnamed forms of *Syringa vulgaris*. It was apparently a semi-double variety, but too far faded or withered to tell.—*W. J. H.*—1, Rose Homère; 2, Marie d'Orleans; 3, *Salvia pratensis*; 4, *Rubus nutkanus* (Salmon-berry); 5, *Rubus laciniatus*; 6, *Rubus phoenicolasius* (Wineberry). Treat the *Rubus* species like Raspberry for fruiting.—*W. E. P.*—*Scilla peruviana*.—*S. G. H.*—*Raphiolepis ovata*.—*Minoriid*.—1, *Anthurium scherzerianum*; 2, *Begonia Rex* var.; 3, *Ornithogalum lacteum*; 4, specimen too scrappy to identify; 5, *Zebrina pendula*; 6, *Tradescantia crassifolia*; 7, *Plumbago rosea*; 8, cannot name without flowers; 9, cannot name without flowers; 10, *Chlorophytum elatum*; 11, *Sparmannia africana*; 12, *Cyperus alternifolius*; 13, cannot name without flowers; 14, *Begonia weltonensis*; 15, *Begonia* sp., cannot name without flowers; 16, *Crassula coccinea*; 17, *Cotyledon* sp.; 18, cannot name without flowers; 19, *Campanula isophylla*; 20, cannot name without flowers. There is nothing wrong with the Vine leaf; it is apparently quite healthy.—*J. J.*—1, *Ocotelea officinalis*; 2, *Saxifraga cuneifolia*; 3, *Saxifraga granulata* flore pleno; 4, *Saxifraga aizoon*.—*M. I., Bucks.*—1, *Spiraea japonica*; 2, *Neillia opulifolia*; 3, *Prunus Padus* (Bird Cherry); 4, *Spiraea Thunbergii*.

SOCIETIES.

NATIONAL HARDY PLANT SOCIETY.

THERE was a very poor attendance at the above society's show, held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on June 4. The competitive classes were feebly contested, except perhaps the class for a decorated table, in which competition was very keen. The trade exhibits were very good, and it seems a great pity that the show was not better patronised. The following is a list of medals awarded:

LARGE GOLD MEDALS.

Messrs. Dobbie and Co., Edinburgh, for a magnificent collection of Antirrhinums and Aquilegias.

Messrs. Kelway and Son, Langport, for a choice assortment of Delphiniums, Paeonies and Pyrethrums, for which this firm has a world-wide reputation.

Mr. James Box, Hayward's Heath, for a most interesting group of hardy flowers, including *Paeonia alba grandiflora* and *P. lobata*. An award of merit was granted to the latter.

Messrs. Piper for a vast collection of hardy flowers, including Saxifrages and Campanulas.

SMALL GOLD MEDALS.

Messrs. H. B. May and Sons for Ferns.

Messrs. G. and A. Clark, Limited, and Messrs. W. and J. Brown, Peterborough, for extensive groups of hardy flowers, in which *Eremurus robusta* was conspicuous.

Messrs. Barr and Sons for an intensely interesting collection of Irises, Lupines and Lilies.

Mr. Amos Perry for Oriental Poppies.

SILVER-GILT MEDALS.

Messrs. Phillips and Taylor, Messrs. T. S. Ware, Limited, and Messrs. Cutbush and Sons, all for groups of hardy flowers.

Messrs. Waterer, Sons and Crisp for a miscellaneous group of hardy flowers, in which we noted *Dianthus inodorus* and *D. dependens*.

Messrs. Sutton and Sons for Aquilegias, a remarkably fine long-spurred strain.

Messrs. Harkness and Sons for an extensive collection of Oriental Poppies and Lupines.

Messrs. James Veitch and Sons for Irises, *Eremuri*, *Anchusa* and other choice hardy flowers.

Mr. Frank Bouskell and Messrs. W. Artindale and Sons for hardy flowers.

SILVER MEDALS.

Messrs. R. H. Bath, Limited, Wisbech, for Tulips, also Paeonies and Lupines.

The Misses Hopkins for rock plants.

Mr. G. W. Miller for herbaceous flowers.

Messrs. Reamsbottom and Co. for St. Brigid Anemones and Lupines.

Mr. Reuthe for beautiful and little-known alpine and shrubs.

Mr. Clarence Elliott for a well-planted garden of alpine. Messrs. Ladhams, Limited, for hardy flowers.

AWARDS OF MERIT.

Campanula Hohinackeri.—Shown by Messrs. Piper. A graceful species, growing about eighteen inches in height. The slender stems are heavily laden with pale mauve blue flowers. It is a biennial, and seeds very freely.

Erigeron Asa Gray.—Shown by Messrs. Artindale and Son. The flowers are uncommon—being light biscuit-coloured—and freely produced about eighteen inches from the ground.

Erigeron hybridus B. Ladhams.—A rosy pink variety with a pleasing bronze tint in the bud. Height 2 feet, very free. From Messrs. B. Ladhams, Limited, Shirley Nurseries, Southampton.

Erysimum linifolium.—A free-flowering alpine with mauve-tinted flowers borne over a long season. Shown by Mr. Clarence Elliott.

Paeonia lobata.—A beautiful species with pink, Tulip-shaped flowers, shown by Mr. James Box.

BATH AND WEST AND SOUTHERN COUNTIES AGRICULTURAL SOCIETY.

THE annual exhibition of this society opened in glorious weather at Swansea on May 28, and for the number of exhibits and general interest it well maintained its reputation of former years. The horticultural section was again a distinct success, and was, in fact, more extensive than usual. Many of the trade firms of the immediate neighbourhood were represented, also others from further afield.

Sweet Peas were a prominent feature, exceptionally noticeable being groups from Messrs. Dobbie and Co., Edinburgh; Mr. W. Treseder, nurseryman, Cardiff; and Miss Hemus, Upton-on-Severn. In the first-named group conspicuous varieties were Dobbie's Orange, Melba, Lavender, King Manoel, Royal Purple and Norma. In the next group Phyllis Bide, Prince George, Scarlet Emperor, Edith Taylor and Maud Holmes attracted attention; while Miss Hemus staged numerous varieties of the Paradise strain, Crimson, Scarlet, White, Amazon and Mrs. Harriet Hemus being all very fine.

Messrs. John Waterer of Bagshot sent a very nice group of Rhododendrons, as also did Mr. James Harris, nurseryman, Blackpill. The latter's group occupied the end of the large tent and also a considerable outdoor space. In addition, he exhibited a large and interesting group of mixed Primulas and St. Brigid Anemones.

Roses were well shown by Mr. Roland Adams, White Wells Nurseries, Bath; Messrs. Walters and Son, Bath; Messrs. George Cooling and Sons, Bath; and Messrs. Paul and Sons, Cheshunt.

For general interest the exhibit of Messrs. R. Veitch and Sons, Exeter, was perhaps the best in the show. In a large and prettily arranged group were found *Sarracenia*, Ferns, Japanese Maples, various stove foliage plants, alpine, and trees and shrubs. Among the latter were finely flowered branches or plants of *Sophora tetralix*, *Buddleia Colvillei*, *Fendlera rupicola*, *Solanum crispum*, *S. jasminoides*, *Tricuspidaria lanceolata*, *Robinia Kelseyi*, *Olearia insignis*, &c. The following plants were also very striking: *Leucopogon Richei*, *Nertera depressa*, *Gerbera* and *Streptocarpus* in variety, *Lathyrus splendens*, *Calceolaria Forgetti*, *C. Golden Glory*, *C. Veitchii* and *Celmisia spectabilis*.

Messrs. Godfrey and Sons, Exmouth, exhibited a large group of Pelargoniums, showing several sections of the genus, while their Oriental Poppies were also very fine.

In a large group of miscellaneous plants, the president of the show, Sir J. T. D. Llewellyn, included Palms, *Schizanthus*, *Azaleas*, *Rhododendrons*, *Primula sikkimensis*, &c.

Begonias were well shown by Messrs. Blackmore and Langdon, Twerton Hill Nursery, the basket varieties *Eunice*, *Golden Shower* and *Gladys* being much admired. The same firm exhibited a fine group of Delphiniums, Carnations and other plants. *Delphinium Lord Curzon* and *D. Statuairi Rude* were specially fine.

Messrs. William Cutbush and Son, Highgate, in a tastefully arranged mixed group included Roses, Carnations, Lilies, Japanese Maples, Palms, *Rhododendrons*, yellow *Richardias* and other plants.

Herbaceous plants, including Pyrethrums, Gaillardias, *Heucheras*, *Incarvillea Delavayi* and others, were shown by Messrs. Rich and Co. of Bath; while Mr. W. Treseder of Cardiff, Messrs. Bakers of Wolverhampton, and Messrs. H. and W. Evans, Cardiff, sent very good groups of similar kinds of plants.

The feature of Messrs. Reamsbottom's exhibit from Geashill, King's County, Ireland, was St. Brigid Anemones, the flowers being shapely and richly coloured. *Centaureas* from Messrs. Jarman and Co., Chard; Pyrethrums from Messrs. Tuplin and Son, Newton Abbot; and Sweet Peas from Messrs. Bide of Farnham were much admired.

Lilies and herbaceous plants were well shown by Messrs. Wallace of Colchester, *Habranthus pratensis*, *Eremuri*, *Allium rosenbachianum*, *Primula bulleyana* and Oriental Poppies being very conspicuous in a large and decorative group. In the same tent Mr. Maurice Prichard exhibited an interesting set of rock plants, while a large and varied collection of rare shrubs was shown by the Donard Nursery Company, Newcastle, County Down.

Ferns and Cacti from Mr. H. N. Ellison of West Bromwich came in for great admiration, the Ferns especially being wonderfully well grown. Carnations from the Countess Cawdor were also much admired.

Messrs. Young and Co., Hatherley, Cheltenham, provided an extensive group of Carnations, in which Scarlet Glow, Mrs. C. W. Ward, Carola, Duchess of Devonshire and the Hon. Lady Neeld were conspicuous.

ROYAL HORTICULTURAL SOCIETY.

THE last meeting was held on Wednesday, June 3, at Vincent Square, Westminster. The show was of a high standard, particularly in respect of hardy flowers; but the attendance was not great, owing, no doubt, to the show being held in holiday week.

FRUIT AND VEGETABLE COMMITTEE.

Present: A. H. Pearson, Esq. (chairman), and Messrs. J. Cheal, W. Bates, J. Willard, E. Beckett, H. J. Wright, A. Bullock, Owen Thomas and W. Poupert.

A silver Banksian medal was awarded to C. Eric Hambro, Esq., The Gardens, Pickhurst Mead, Kent, for a group of Melons.

ORCHID COMMITTEE.

For the first time for a very long while no awards were made to new Orchids. There was, however, an unusually long list of novelties to gain awards from the floral committee, which more than compensated for the lack of novelty among the Orchids shown on this occasion.

The following awards were made to groups of Orchids:

Silver Flora Medals.—H. T. Pitt, Esq., Stamford Hill; Messrs. Sander and Sons, Messrs. Charlesworth and Co., Messrs. Stuart Low and Co. and Messrs. Armstrong and Brown.

Silver Banksian Medals.—Messrs. Hassall and Co. and Messrs. J. and A. McBean.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. W. A. Bilney, E. A. Bowles, W. J. Bean, J. W. Barr, G. Reuthe, J. W. Moorman, C. E. Fielder, C. Blick, W. Howe, J. Jennings, W. Bain, R. W. Wallace, C. E. Shea, G. Paul, W. Cuthbertson, W. P. Thomson, J. T. Bennett-Poß, E. H. Jenkins, J. F. McLeod, W. H. Page, F. W. Harvey and A. Turner.

Messrs. R. H. Bath, Limited, Wisbech, staged a nice lot of Sweet Peas and Tulips. Of the former, Scarlet Emperor, Orange Perfection, Walter P. Wright (lavender), Lady Miller (pink and cream), Glow (a nice shade of orange scarlet) and Lillian (pink) were some of the more distinct. Of the Tulips, *gesneriana lutea*, Orange Globe, Parisian Yellow, Flambeau, Baronne de la Tonnaye (fine rose) and *Moralis* (rich purple) were among the best.

Messrs. Dobbie and Co., Edinburgh, arranged a glorious bank of Antirrhinums and Sweet Peas, the former in the three sets of Tom Thumb, medium and major varieties, and perhaps nothing in the show attracted a greater share of attention. Snapdragons are everybody's flowers, and may be grown by all. Of the more important we noted Maize Queen, Amber Queen, Rose Queen, Yellow Queen, Sunset (red and yellow) and nobile (which embraces the shades of colour seen in the *Dendrobium* of that name). These all belong to the medium set. Cottage Maid (crimson), Queen of the North (fine white), Delicata (pink and white) and Tom Thumb (white) were all good. The Sweet Peas were an equal success and finely grown. Lavender G. Herbert, Melba, Dobbie's Orange, Dobbie's Cream, Frilled Pink, Alfred Watkins (a fine lavender) and Thomas Stevenson (orange scarlet) were among the best vases of these flowers.

Messrs. John Waterer, Sons and Crisp, Limited, Bagshot and Twyford, set up a bank of Irises, Lupines, Pyrethrums and Poppies. All were in very charming array, and quite representative of their class. The Irises of the pallida set were very beautiful and in fine array. Gaillardias, too, were well shown. At one end of the group choice alpine were staged, *Lewisia rediviva* and *Dianthus alpinus albus* being among the more important.

Mr. George Prince, Oxford, displayed an interesting lot of Rose species and varieties. The rarer kinds included *Rosa hemisphaerica*, golden yellow, flowers very double; *R. watsoniana*, with very fine foliage; *R. ochroleuca*, yellow flowers, small foliage; *R. nitida*, virtually a pygmy *R. rugosa*; and *R. spinosissima*, pale yellow. *Comtesse de Nadaillac* among Hybrid Teas was very charming.

Messrs. R. W. Wallace and Co., Colchester, had a delightful lot of Irises, both species and varieties. In the Flag section we noted such as Miss Wells, *Isolene*, Kashmir White, *flavescens*, Lady Foster (a lovely blue pallida form of great stature), Kashmir (fine blue) and Caterina (a grand pallida form nearly four feet high). Hybrid forms of Cushion and other Irises were also on view; also the white-flowered form of *I. laevigata*, a most graceful plant.

Messrs. H. B. May and Sons, Edmonton, had a nice display of *Heliotrope*, *Hydrangea* *Mme. Moulière*, *Fuchsias*, *Verbena* Miss Willmott and V. King of *Scarlets*. The pink-flowered *Verbena* Miss Willmott was particularly good, well-flowered examples being shown in 5-inch pots.

Mr. H. Burnett, Guernsey, had a very fine assortment of Carnations, the handsome flowers well disposed in large vases. Carola (crimson), Salmon Enchantress, Marmion, Monarch, Snowstorm, Pluto (crimson), Mandarin (fancy), Mary Allwood, Enchantress Supreme, Mrs. Clode, Geisha and Scarlet Glow were the more prominent.

Messrs. Kelway and Son, Langport, Somerset, had a capital table of Paeonies and Delphiniums, Wilbur Wright (crimson), Balliol (pink), Purity (white) and Homer (double pink) being among the best.

Messrs. Stuart Low and Co., Enfield, had a fine show of Carnations Princess of Wales, Baroness de Brien, Gorgeous, Carola, Princess Juliana and Venus, the last, a pure white Perpetual Malmaison, being very fine.

Messrs. H. Cannell and Sons, Eynsford, Kent, had a full table of rambler and pillar Roses, of which Lady Gay, American Pillar, White Dorothy, Blush Rambler, Dorothy Perkins, Excelsior (very rich and beautiful in colour) and Dorothy Dennison were all very fine. The whole of the plants were pot-grown examples about six feet high and flowering most profusely. The plants made a great show.

A view in the Rose Garden at Hallingbury Place, Bishop's Stortford.

THE GARDEN.

No. 2222.—Vol. LXXVIII.

JUNE 20, 1914.

NOTES OF THE WEEK.

To Our Readers.—To meet the wishes of many of our readers, we have decided to publish *THE GARDEN* a day earlier than usual. Copies should now be on sale at all London book-stalls and newsagents on Wednesday morning instead of Thursday as hitherto, and in the provinces on Thursday morning instead of Friday. We shall be glad if any reader who experiences difficulty in obtaining *THE GARDEN* regularly will communicate with us.

Eremurus robustus.—The tall, stately spikes of *Eremurus robustus* make a striking appearance in many gardens in June. It is a native of Turkestan, and difficulty is sometimes experienced in its cultivation. It does best when given deep, rich, well-drained soil on a south border. The illustration depicts a group of this noble plant flowering on a sunny slope in Sir Frank Crisp's gardens at Friar Park, Henley-on-Thames.

A Pleasing Combination.—*Eucalyptus globulus* makes a very pretty decorative plant, particularly when used in combination with *Delphiniums* of various shades of blue, the glaucous hue of the foliage of the one forming a harmony of colour with that of the flowers of the *Delphiniums*. If such beds are edged with one of the red *Lobelias*, *cardinalis* or *fulgens* or their varieties, they will give a pleasing effect.

Useful Plants for the Greenhouse.—We were very much pleased the other day by a fine group of *Calceolaria Clibranii* intermixed with *Nicotiana Sanderæ*. All the plants were well grown, and made a very attractive display. Both are easily raised from seed, and require little attention. *Begonia Lloydii* mixed with well-grown plants of *Lobelia tenuior* also formed a very pleasing combination.

Tomato Disease in Seed.—The current issue of the *Kew Bulletin* contains an interesting article on the hibernating of the mycelium of the black spot Tomato disease, *Macrosporium Solani*, in the seeds of infested fruits. It has been proved conclusively that the mycelium can, and does, actually exist in the tissue of the seeds, as well as in the form of a web on the outside of the integument. It is pointed out that seed should on no account be saved from diseased fruit, even if the black spots are not present.

Pink Roses and Blue Alkanet.—A very charming floral combination that we have in our garden just now is provided by the beautiful

glowing pink Rambler Rose *Tausendschön* and the Dropmore variety of *Anchusa italica*. The Rose is scrambling over a trellis fence, whence its festoons of flowers are flung in many directions, and the *Anchusa* is growing in the border immediately in front. Between the tall masses of blue one gets glimpses of the Rose, and the effect is very telling. It loses none of its charm by the fact that the grouping was quite accidental.

which it blooms no more until the following June; while the Rose from the cutting continues to flower all through the summer and early autumn. This difference has been observed for a number of years. That the two trees are from the same variety there can be no doubt, for the Rose on its own roots was raised from a cutting of the tree on the wild Briar stock.

An Attractive Plant for the Rockery.—

In *Eriogonum umbellatum* we have an alpine of a distinct type, with pleasing and massive umbels of yellow flowers on a thick scape. The base of the plant also presents another pleasing feature; there we see a circular arrangement of its spoon-shaped leaves, whose stalks are beautifully tinted with red on the upper side. The effect is that of a bright red rosette, and the contrast is very beautiful with the yellow blooms and grey foliage. The bright colouring is only developed when the plants enjoy sunny weather.

Viola cornuta purpurea.—This perfectly hardy floriferous little plant deserves to be more widely grown than would appear to be the case. Somewhat resembling single blue Violets, the freely produced flowers possess an advantage over many of the dwarf growers by reason of their long, slender stems, making them suitable decorative subjects when cut. They are useful as borderings for Rose or other beds, looking well in our own garden associated with bushes of *Frau Karl Druschki*. *Viola cornuta purpurea* thrives quite happily in practically any soil, and flowers continuously throughout the summer and autumn without special attention beyond the usual occasional removal of spent blooms. Cuttings root freely in frames in the autumn.

Variation in the Lyon Rose.—It is well known that the blooms of this exquisite Rose show a great tendency to vary. Even Roses on the same bush are sometimes remarkable for their dis-

similarity. At the same time there are unquestionably inferior stocks of this variety in commerce. This was recently brought very forcibly to our notice in a garden where stocks of this variety, obtained from English and French growers, were seen flowering under similar circumstances. In each case the English-grown Roses showed a far greater depth of colour, while there was also a decided difference in the foliage of the plant.

A NOBLE BORDER PLANT, EREMURUS ROBUSTUS, IN THE GARDENS AT FRIAR PARK.

Roses on Their Own Roots.—It is a very debatable point as to whether Roses are better on their own roots or when budded on a wild stock. The differences are sometimes interesting. At the present time we have under notice two fine plants of *Alister Stella Gray*. The plant worked on to the wild Briar flowers a clear fortnight before the other, which was raised from a cutting. But the first Rose to flower is soon over, after

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Early Loganberries.—On June 7 I picked off a Loganberry bush on a wall in my garden with a west aspect half-a-dozen fruits, quite ripe. This is abnormally early for me, and I would be interested to know if it is unusually early in other gardens.—S. A. W. WATERS, *County Dublin*.

A Scottish Lady Gardener.—The Rev. David R. Williamson desires us to say, with reference to his article on "A Scottish Lady Gardener," in our issue for the 6th inst., that the rock gardens and Water Lily pond at Logan were both designed and laid out by Mr. McDouall, who, as indicated in the article in question, is an earnest horticulturist, and takes the deepest interest in his gardens and grounds.

Three Good Climbers for May and June.—I am enclosing a small photograph of a temple

the photograph demonstrates, moraine treatment suits it admirably. I am happy to say that, though usually I have to depend upon division for its propagation, the present *annus mirabilis* has caused it to set a plentiful crop of seeds. This *Primula* must not be confounded with the totally distinct true *P. nivalis*.—RAYMOND E. NEGUS, *Walton-on-Thames*.

Narcissus triandrus calathinus.—Of all the *Narcissus* species, this is perhaps the most beautiful. Originally found by the late Mr. Peter Barr in the Isle of Glénan, off Brittany, it is now reported to be almost extinct there. It is, however, remarkably free-seeding under cultivation, and considerable stocks of it have now been worked up by careful cultivators, so much so that the price, which a few years back was as much as 3s. 6d. a bulb, has now come down to 1s. It has been much employed by hybridists as a pollen parent, and such lovely flowers as Alabaster, Madonna and Alys have resulted from its use. As a plant it is quite on the small side, and gives

decrepit, having been allowed to grow without pruning or attention in the way of feeding. When Mr. P. Smith, the present gardener, took charge, he suggested cutting it well back, and also lifting the pavement of the conservatory to allow the plant to be supplied with water and other nourishment. This has been done, and the Myrtle is again showing renewed vigour and looks as if it would be in capital condition shortly.—S. A.

Roses and Clematises.—In the issue for June 13, page 301, is a note upon the beauties of these flowers when suitably used in combination. I have had some remarkably pleasing results from these, and give a few short notes upon a good method of cultivation. The Roses most suited, or at any rate those not harmed by the Clematis, are found chiefly among the strong growers that only produce one good show of bloom early in each summer. Quite a number of our beautiful and earliest flowering pillar and wall Roses are found among these. Carmine Pillar, with the Crimson and Blush Ramblers, *Hélène*, Goldfinch, Psyche, Tausendschön and some of the Ayrshires may be mentioned as good examples. The selection of Clematises seems best if confined to those known as the Jackmannii section, which carry their main crop of flowers upon the long growths of the same season. They also flower from the end of these growths first, and then bloom backwards along the strands of wood. Being thus late in flowering, they follow with a beautiful display after the Roses, and so fill in what would otherwise have been a rather serious gap. There is a second decided advantage in the Jackmannii section, for we can cut away all dead growth when pruning the Roses early in the spring. These Clematises can be cut down to their base, and so allow of a clear start each season.—A. P.

The Vitality of Seeds.—In your issue of May 2 Mr. Charles Comfort gives some interesting cases of the vitality of seeds. The following is within my own experience. Some years ago I prepared a piece of pasture land for planting trees. This land had been under grass for at least thirty-five years. Now it is well known that Charlock, or Ketlock as it is called in Lancashire, is never found growing in pasture land, yet the season after this land had been turned over it was quite yellow with Charlock, the seeds of which must have been lying dormant for over a third of a century. I remember, many years ago, an arable field on the Wiltshire Downs which was (*mirabile dictu*) practically free from Charlock, and was in consequence a source of some pride to its owner. The custom there was to plough only 2½ inches deep, owing to the close proximity of the underlying chalk. A new ploughman set his plough 3 inches deep, and the next summer that field was a glorious sight to anyone except a farmer, being a mass of yellow from end to end. From this it would appear that Charlock will not germinate at a depth of 3 inches. Stranger still, when buildings are cleared away in a town, the site often becomes clothed with wild plants. This is said to have been the case on the Aldwych site in the Strand. Perhaps some reader can confirm this.—WALTER DE H. BIRCH, *Walton-le-dale, Lancashire*. [Our correspondent is quite correct about the Aldwych site, but we think that the seeds of most of the vegetation there came from manure or from the feed-bags of horses.—Ed.]

PRIMULA HIRSUTA NIVEA ON THE COOL SIDE OF A MORaine.

in these gardens, showing the Yellow Banksian Rose, Clematis montana and Polygonum baldschuanicum. The Rose and Clematis have been a picture since early in May, and even at this date (June 10) are still smothered with flowers. I find the best time to prune them is immediately after they have flowered.—G. BURROWS, *Shendish Gardens, King's Langley, Herts*. [We regret that the photograph was not sharp enough for reproduction.—Ed.]

A Beautiful Hardy Primula.—I enclose a photograph of *Primula nivalis* of gardens, which we are told is really *P. hirsuta nivea*. I trust that you will find space for its reproduction, since I think that this beautiful *Primula* scarcely receives the attention it deserves. In my opinion it is head and shoulders above any other rock garden *Primula*, and I enjoy its annual display of snowy blossoms upon the cool side of my moraine as much as any other floral spectacle of the year. It is not fastidious in its wants, provided it is not allowed to suffer from drought. But, as

most pleasure when grown in pots and pans in a frame or cold house; but its extreme value for breeding purposes will always make it indispensable to anyone interested in hybridising, even in a small way. The pollen of its hybrid offspring, by the way, is not nearly so effective. It is the true species itself that should always be used.—ORNATUS.

An Interesting Old Myrtle.—There is an interesting plant of the Myrtle, *Myrtus communis*, in the garden of F. S. Hay, Esq., at Duns Castle, Duns, Berwickshire, where it has been since 1803. It originated from a sprig worn by the well-known beauty of the day, Miss Lucy Johnston of Hutton Hall, at a ball in 1777 or 1778. As there was no glass at Duns Castle at that time, the cutting was struck in another garden, and the plant came to Duns Castle in the year mentioned. It was planted out in a conservatory, and eventually assumed large dimensions, and was the cause of the house being named the Myrtle House. Within recent years it became somewhat

Primula Leddy Pilrig.—Though this is very like a derivative of *Primula pulverulenta*, there is no reason to doubt that its habit and general appearance are derived from *P. bulleyana*. Messrs. Stormonth of Carlisle possess a similar hybrid, but of a darker tint of salmon rose. The *Primula* family is full of surprises, so we need not wonder if the above is another. For the second time I secured a bit of *P. cockburniana* last year, an offset from an old plant, and it is flowering now and quite healthy, shaded by a large stone, where I am hopeful it will be perennial to a degree. Previously it proved an annual. The new *P. Juliae* exhibits a habit that renders its increase very easy. The young growths throw out roots as they push their way along the surface of the ground, and nothing could be easier than offsetting these and establishing them as single plants. It seems also to produce seed abundantly.—B.

Flowering Trees.—The wealth of blossom on trees, surpassing that which we usually see, has afforded a means of comparison of extreme importance. At the time of writing, Thorns are in the ascendant, and palpably the best decorative forms are pure white and crimson, represented by Paul's Double Crimson. Double Pink, which is rather rose than pink, is also good, but light pink or blush, of which we find several tints here, are largely ineffective. *Crataegus Aronia* is blossoming and is the best at present, but less effective than the common Thorn. A note may also be made of the quiet beauty of Rosemary, which is flowering more profusely than usual, and unpruned bushes of the commoner Roses are beginning to show what they will be very shortly. Colours seem to me to be much deepened; Fellenberg, for instance, approaches crimson, and *Rosa hemisphaerica* has the petals curiously edged with lightest green.—R. P. BROTHERSTON, *Prestonkirk, N.B.*

School Shows.—I was interested in the letter on school shows that appeared on page 235, issue May 9. I was attending a show at Wallingford recently, held under the auspices of the Oxfordshire Agricultural Association, and among the tents was one allotted to the children of schools in Oxfordshire. Prizes were given by private donors and the Oxfordshire Education Committee, and I should say that this proved to be one of the most interesting tents of the whole show. Not the least interesting of the exhibits were the pen drawings of bulbs and the various plants grown by the aid of different manures. These included Lettuce, Cabbage, Peas, and Potatoes, each lot bearing a label giving details as to the amount and kind of manure used. I think that we as parents have no need to wonder (when looking round such a tent) why our children are anxious to go to school, rain or snow, hail or blow. School must have an attraction for them such as it never had for us. Work of this kind must be of considerable educational value to the children and of real service to them in after years.—A. CRANSTONE, *The Gardens, Brightwell Park, Wallington, Oxon.*

FORTHCOMING EVENTS.

June 24.—Richmond (Surrey) Flower Show. Croydon Horticultural Society's Flower Show. Brighton Horticultural Society's Outing to Viscountess Wolseley's garden at Glynde.

June 25.—Isle of Wight Rose Society's Show at Ryde (provisional). Sherborne Floral Fête.

June 27.—Windsor, Eton and District Rose and Horticultural Society's Show.

COMPETITION FOR PLANNING AND PLANTING THE LITTLE GARDEN.

AS promised, we publish below replies to the queries which we have received in connection with our competition for planning and planting the little garden. We would remind readers that there is still plenty of time for entering this competition, in which we are offering cash prizes to the total value of £33 12s., as well as a number of book prizes, for the best designs. Competitors may send in designs for one, two, three or four sites, as there are separate prizes for each. Any competitor may send in more than one design for any of the plans. The coupon will be found on page iv.

Fences.—It is to be assumed that each plot is enclosed by a cleft oak fence 5 feet high. Competitors may mask this with plants in any way they think fit.

Locality.—Competitors should assume that all the designs could be carried out in gardens in the London district or the Midlands.

Tennis Courts in plans Nos. 3 and 4.—It is ideal that a lawn tennis court should be 120 feet by 60 feet, and should face north and south rather than east or west; but when a site is of limited size and the position cannot be altered, designers have to do the best they can in the existing conditions. The sites were purposely chosen to present difficulties which frequently occur. The competition is intended to be practical, not ideal. A court 40 feet by 140 feet is often as large as can be provided in a small garden.

Perspective Drawings.—It is not necessary to send a perspective drawing of each, or of any, plan; this is left to the competitor's discretion. Elevations of garden-houses, or of other architectural features, may be drawn on the third plain sheet if desired, instead of, or in addition to, a perspective view. A model may be sent in place of the perspective drawing if the competitor so desires.

Cost of Plants and Labour.—It is not practicable to fix a schedule of prices for different localities. In fixing the sums to be spent, the cost of labour is not taken into account; but elaborate schemes involving an amount of work which the owners of such gardens could not reasonably afford will be disqualified. A tool shed may or may not be included.

Prices for paving or for plants should not be mentioned. Details as to how the allowed sums are allocated need not be given.

Position of Sites.—No. 4 site can be assumed to be in the country or an outlying suburb.

Type of Houses.—It is assumed that the dwelling-houses are of the ordinary gable type. The walls of the house may be covered with climbers at the competitor's discretion.

Effects Desired.—The judges will base their awards on the effect which may be expected within a reasonable time of planting. Each garden should be planted so as to give a good effect for as long a period of the year as possible.

Planting Plans.—These must give the details of beds or borders shown in outline on the plans. If all four designs are attempted, four planting plans of beds and four of borders must be submitted.

Entrance Drive or Path.—This is not already designed, and should be shown on plan.

Garden Seats, Trellis, Pergolas, &c.—These may either be purchased or made at home, but cost must be considered.

Any competitor who has sent an enquiry not answered here in detail will please assume that the point raised is left to his or her discretion.

No further enquiries can be answered.

Competitors are at liberty to pin to their designs a descriptive memorandum not occupying more than one side of a foolscap sheet.

The last day for sending in designs is September 1, 1914. Any time up to August 20 the sheets of site plans on which the designs are to be drawn can be had on sending 4d. in stamps to the Editor.

SOLANUM CRISPUM.

THIS beautiful and free-growing Chilean plant, commonly known as the Potato Tree, is considered by many to be only half-hardy, and this wrong impression undoubtedly deters many persons from planting it outside. It is a robust and free-growing shrub from 12 feet to 16 feet high, with conspicuous bluish purple, fragrant flowers during May and June. It is not particular as to soil, and will be found an excellent subject for quickly covering a blank wall. After flowering is over, all weak wood should be removed to encourage new strong growths, which often attain a height of 8 feet to 10 feet in a summer, and it is upon these the flowers are borne the following year. In Cornwall it forms large bushes in the open, but in most parts of the country it needs the protection of a wall, where it will prove a very worthy subject. B.

NOTES ON CARNATIONS.

THE earlier border Carnations in pots, e.g., Lady Hermione and Leander, are at the time of writing producing flowers, and there will be an uninterrupted supply till those in borders and beds come in. Though there is plenty of bloom on Perpetuals, there is yet room for a selection of border varieties, and there are always the lovely bizarres, flakes and fancies in Carnations and the delicately refined Picotees of both sections, yellow grounds and white grounds, which I am hopeful will not always suffer the neglect they do at present. Whoever has given them the ordinary attention they ask for, which implies all along cool treatment, cleanliness and ventilation to the fullest extent, according to weather, agree that there is no difficulty in their cultivation.

The more recent varieties are, moreover, constitutionally very much more robust, and produce considerably more roots than the older ones they have superseded, and it is, consequently, easier to keep a healthy stock than at one time was possible for the ordinary cultivator. I strongly recommend gardeners to add a selection to their summer-flowering pot plants.

There is no reason to hurry the propagation of Malmaisons. One of the most successful growers I know—the most successful, indeed—does not begin to layer his plants till the end of July or the beginning of August. The layers root at that time very rapidly, and the cooler nights seem to affect the whole system of the young plants in a manner that induces a rapid growth, which ensures complete establishment

before winter sets in. It is usually desirable to select the healthiest plants for propagation, and if, as sometimes happens, disease has laid hold of all, then the layers should be made from the extreme tips, just long enough to secure a firm bit of shoot for rooting. These make far better growth than longer pieces with diseased leaves, and with careful treatment through the autumn and winter provide by no means unsatisfactory flowering plants.

Before these notes appear, the bulk of the Perpetuals will have been placed into their flowering receptacles and the important item of staking be engaging attention. Very strong, well-branched

THE NEWER CHINESE RHODODENDRONS.

(Continued from page 304.)

R. Fargesii, collected by Mr. E. H. Wilson during his first journey for Messrs. Veitch, has dainty rose pink, tubular flowers. As these open rather early in April, this is one of the species which Rhododendron enthusiasts in the South and West should cultivate, as it promises to be a good thing.

R. flavidum (primulinum).—Flowering when only a few inches high, this alpine species is valuable

half the length of the shoots, which reach 3 feet in height. This species seeds freely.

R. siderophyllum.—Flowering towards the end of April, this may be described as a "good-natured" plant, being free in growth and profuse in flowering. We have plants, 4 feet in height, a mass of pale blush-tinted blossoms with dark brown spots, individually half an inch across.

R. Souliei.—The glaucous green foliage and red-stalked leaves of this species give the plants a very distinct appearance. The rosy pink flowers are also markedly distinct, being 3 inches across and almost flat. A May-flowering Rhododendron.

R. sutchuenense.—This species forms a good-looking evergreen bush, with stout, leathery leaves up to 9 inches long. The rose-tinted flowers are bell-shaped and about three inches across. Our one regret in the London district is that the flowers open in March. It is worth trying in pots for greenhouse decoration.

R. yanthinum.—There are several purple-flowered species, and this at present is the most pleasing, being a rich glowing vinous purple. It flowers the second half of April, the individual blooms being $1\frac{1}{2}$ inches to 2 inches across. There seems to be no botanical difference between this species and *R. benthamianum*, though the flowers of the latter lack the rich colouring which is such a feature of *R. yanthinum*.

R. yunnanense.—Introduced to France by Abbé David in 1889, this must be accounted as one of the most useful garden plants. At their best about the middle of May, the plants blossom so freely as to almost hide the leaves. There is considerable variation in the white, blush-tinted flowers, which are spotted with reddish brown.

A. O.

SOME OF THE NEWER RAMBLER ROSES.

THESE are some delightful novelties among Rambler Roses that all who can find space for them should plant. One of the best is Marie Henriette Gräfin Chotek. This is how its raiser, Herr Lambert, styles it, so I suppose it is correct, although in some lists I find the word "Gräfin" placed first. This beautiful Rose is now (June 2) opening with me, and its flowers are like miniature Richmonds. It is a remarkable cross—The Farquhar x Richmond—for it possesses none of the Wichuraiana habit, but rather that of the Multifloras. This Rose blooms in clusters of three and singly, and although there is not the intense effect there would be from a pillar of Excelsa, yet the flowers are so useful for cutting that no one can afford to overlook it.

White Tausendschön will be wanted in every garden of fair size, for it is a most delightful kind and extremely showy. The colour is not exactly white, there being a faint suspicion of blush pink, while at times one can have two colours upon one plant. Both this and the ordinary Tausendschön would be more effective if the growths on each plant were reduced to two or three; then, by judicious feeding, we may have glorious big trusses and blooms. To plant at the base of White Tausendschön I can strongly recommend a lovely new dwarf kind named Echo. It is one of Lambert's, and is a great improvement on Louise Walter, the so-called Baby Tausendschön. I should like to see more of this effective planting of ramblers and the Dwarf Polyanthas,

RHODODENDRON SIDEROPHYLLUM. THIS IS A NEW CHINESE SPECIES WITH PALE BLUSH FLOWERS.

plants require more than one stick—some three, and very large ones with numerous shoots as many as five. By no means should the tying of the shoots at any time be neglected. Straight growths are an essential of success, and, apart from that, very vigorous shoots, if unsupported, are apt to snap off. The final stopping of the plants requires much consideration, and must be determined by local circumstances as well as by the habit of particular varieties. Seasons also have a very decided effect. The heat of last summer threw one considerably out in calculating just when to cease stopping. Some of the newer varieties may be stopped later than others. Triumph and Empire Day are examples of those that come on very rapidly, while Carola and Baroness de Brien are very slow, and cannot be stopped later than June. Lady Northcliffe has also been very slow in the autumn. Some are really late winter or spring flowerers, such as Alma Ward and R. F. Felton, which are really wonderfully beautiful then. The Hon. Gladys Fellowes, which Mary Allwood supersedes, is a very consistent producer. Continue limited applications of stimulating manures to all Carnations planted out, and keep aphids away by means of dustings of Tobacco powder.

Prestonkirk, N.B.

R. P. BROTHERSTON.

for sheltered nooks in the rock garden, apparently not exceeding $1\frac{1}{2}$ feet to 2 feet in height. The yellow flowers, about an inch in diameter, are terminal, three to five in a cluster, opening during April.

R. intricatum.—This pretty alpine species, which flowers early in April, was the subject of a coloured plate in THE GARDEN for June 6.

R. lutescens.—This is a rather tender April-flowering species with yellow flowers. It is readily separated from *R. ambiguum*, the flowers being terminal and axillary, towards the ends of the shoots singly or in pairs. This plant reached us first from France, and later Mr. Wilson sent home seeds.

R. polylepis (harrovianum).—Of this species a very considerable number of plants are already in commerce. It forms a nice bushy plant, but requires a sheltered spot, the leaves suffering from cold winds in exposed positions. The flowers are purple, $1\frac{1}{2}$ inches to 2 inches across, opening during April.

R. racemosum.—It will not be necessary to do much more here than mention this species, which is one of the most distinct and valuable Chinese Rhododendrons for the rockery, beds and borders. It was one of the first species introduced by the French in 1889. The white-tinted flowers are freely borne on the growths, often clothing

as one may now have almost any colour, either to harmonise or to contrast.

Christine Wright is a fine hybrid with very large blooms of a Dog Rose colour.

Kalmia is a grand new single. The foliage is a dark glossy green, and the flowers are white, with the upper half of the petals tinged with pink, producing a beautiful effect.

Braislwick Charm is the nearest approach to the Perpetual Wichuraiana. In some respects it resembles Alberic Barbier, but is quite distinct. The blooms are borne in light, artistic clusters, which renders it most valuable, and until we obtain a real golden Dorothy Perkins it will fill the gap, for the open flowers have quite a rich yellow colouring in the centre.

Lisbeth von Kameke is a seedling of the Blue Rambler, Veilchenblau, and is a very distinct shade of pale violet. This and Sweet Lavender, another of the bluish-tinted Roses, will lend a most beautiful effect among ramblers if tastefully grouped among the whites or creams.

Ethel is a lovely and most dainty rambler, producing graceful sprays of semi-double flesh pink flowers, and one specially useful for cutting purposes.

Mrs. M. H. Walsh and Lady Blanche are two fine new white ramblers, and will doubtless supersede White Dorothy, which is really not pure white. I also think the Rev. J. H. Pemberton's new white will be an acquisition to the Multifloras, for we have no good white in that section save Thalia, and this is much better. Dorothy Jeavons, a white sport of Blush Rambler, is rather a poor thing. Of course, we have Waltham Bride, a lovely early bloomer and deliciously fragrant; but this seems to me to be a different type to the Multifloras, more like a Hybrid Noisette, excepting that it blooms but once.

Sodenia will become a great favourite. It comes midway in colour between Minnehaha and Excelsa, and yields enormous trusses in great profusion.

Jean Guichard is fine, one of the type represented by Leontine Gerbaud and Desire Bergera. It is a fine addition, and is now some seven years old, but not much known.

Miss Helyett belongs to the large-flowered section of the Wichuraianas. The flowers are as large as an ordinary-sized Tea Rose, and as it is early flowering—opening now, in fact (June 2)—it will be a valuable addition. The foliage is delightfully glossy, and the flowers are rosy pink, with salmon pink centre.

Coronation is a lovely colour, bright scarlet, splashed with small white streaks. It is an effective rambler.

Source d'Or is golden yellow, passing to paler yellow. The trusses are not large, but it is a fine addition to the Wichuraiana group.

Perle von Wienerwald is a grand sort for its lasting qualities when cut. The huge trusses carry blooms fully 1½ inches across, and are of a lovely carmine pink inside and Carnation pink outside.

Sanders' White is one of the best additions to the double white Wichuraianas, and it has the

merit of being pure white. There are others under observation, and further notes on these will follow.

Other promising novelties are the Climbing Orleans Rose Donau, an improvement upon Veilchenblau; and Geisha Grüss an Freudendorf. Perhaps this will prove to be the best dark red Wichuraiana.

DANECROFT.

COLOURED PLATE.

PLATE 1496.

A BEAUTIFUL ROSE GARDEN.

It has become the custom in gardens of goodly dimensions to devote a portion entirely to Roses, or to Roses and plants that associate well with them. This plan is an ideal one, for the visitor is then able to compare the different varieties and to note the effect that each is capable of producing. Again, many—indeed, most—Roses give much better effects when grouped in good-sized

of Mrs. Lockett Agnew, who takes a very keen interest in practically all branches of horticulture. Although it has been impossible to reproduce the colours as true as we would wish, the plate serves to show what a charming effect can be obtained by grouping other plants of suitable character in the Rose garden. Here we find the Madonna Lily making a delightful foil to the more vivid Roses, while in the foreground sufficient of a bed of Nepeta Mussinii is shown to give an idea of what effect the association of red, white and lavender blue is capable of creating.

The pergola runs the whole length of the Rose garden, the brick pillars that support the Oak framework above being creased at about every fourth layer with old tiles. Near the pergola, but not shown in the coloured plate, is a paved pathway bordered with Lavender, out of which rise stout Fir poles at intervals of 8 feet or 10 feet, and each to a height of about five feet. These support a stout rope, along which climbing Roses, mostly of pink shades, are festooned. Clematises are largely used in this garden in association with Rambler Roses, pale lavender

A FINE BUSH OF THE NEW CHINESE RHODODENDRON YUNNANENSE.

masses of one sort than when grown as isolated varieties. Added to this we are able, with the aid of the simple Larch pole, or more pretentious pillar or pergola, to grow the many beautiful rambler varieties in association with those of dwarf form, and so realise the wonderful diversion, not only of colour, but of habit and time of flowering, that exists among members of the Rose family.

The coloured plate presented with this issue depicts a scene in the Rose garden at Hallingbury Place, Bishop's Stortford, the charming residence

of Mrs. Lockett Agnew, who takes a very keen interest in practically all branches of horticulture. Although it has been impossible to reproduce the colours as true as we would wish, the plate serves to show what a charming effect can be obtained by grouping other plants of suitable character in the Rose garden.

A CHARMING YELLOW ROSE.

WHAT a beautiful Rose Marquise de Sinety is! This year it has commenced to flower very early with us, earlier, indeed, than most of the other Hybrid Teas, and owing to the cool weather the blooms have come a really wonderful colour, best described, perhaps, as burnished orange yellow. Its dark maroon red foliage is so leathery as to successfully withstand mildew when many others fall a prey.

WORK AMONG THE OUT-DOOR FLOWERS.

WHEN, the other day, pacing alongside the flower borders with an old friend and well-known gardener, he remarked that there was an immense amount of staking looming in the near future. "Not so," I replied, and pushing up the string that encompassed the stems of one plant, I showed him how very simply and yet how efficiently a strand of string wound loosely round a plant was sufficient to preserve it in the upright position without the aid of a stake. The staking of herbaceous plants is to a very large extent a delusion, and beyond a few that cannot be managed without the support of one or more stakes, the great majority perform their delightful functions all the more satisfactorily unstaked. Those that would give way under the stress of a

About Dahlias.—Just at present our Dahlias are receiving the one necessary attention they need to keep them right for the whole season. This is effected not by means of stakes, but with stout, hooked pegs, or more usually with pieces of Snowberry bent like a hairpin, with which a selected number of shoots are pegged to the ground. As a rule, this is a far more effective manner of treating Dahlias for decorative purposes than the use of any number of stakes and ties. You will remember how that all-round florist Mr. William Cuthbertson mentioned at a Dahlia Conference that the finest display of Dahlias he had ever seen was what he termed a hedge of them in the gardens here. These were produced without a single stake—merely by once pegging down.

Pruning Hardy Flowers.—One should never be afraid to use the knife when obviously needed, which happens very often throughout the summer and autumn. Repeated prunings keep such a vigorous plant as *Anchusa italica* in due bounds,

THE ROCK GARDEN IN JUNE.

THERE are two of Loudon's gardening rules that seem most applicable to the rock garden at this season, viz., (1) "Never pass a weed without pulling it, unless time forbids"; and (2) "Let no plant ripen seeds, unless they are wanted for some purpose, useful or ornamental, and remove all parts that are in a state of decay." Both are common-sense rules, but a point that is sometimes overlooked is that certain rock plants are very attractive when fruiting. Take, for instance, the Pasque-flower (*Anemone Pulsatilla*), which at the present time is very attractive by virtue of its heads of downy seeds, and the same may be said of the light, feathery heads borne by *Geum triflorum*. While many rock plants are now passing out of bloom, there are, happily, scores of others to take their place. The rock garden should be in the height of its beauty in June. The large family of Mountain Pinks are now at their very best. *Dianthus plumarius* is one of the best and most showy of them all, while others worthy of special note are *D. cæsius* (with bright pink flowers about four inches high), *D. deltoides* (of a deeper hue), *D. neglectus*, *D. alpinus* (with large, expanded flowers borne close to the ground) and *D. Tenorei* (with white flowers on slender stems). Some of the alpine Pinks are difficult or even impossible to identify, for they are so freely crossed by bees, and self-sown seedlings are common. The mention of bees serves to remind one that certain flowers are much more favoured by their visits than others. The bees are never tired of visiting the small pink flowers of *Thymus odoratissimus*, and so long as this remains in flower the bees are always in attendance.

Saponaria ocymoides, a plant belonging to the same Natural Order as *Dianthus*, is now flowering in profusion. It is a pretty trailing species, with small leaves and bright pink flowers, and is seen to best advantage when allowed to overhang the rocks.

In shady places *Ramondia pyrenaica* and *Arenaria balearica* look charming when grown together, the former, with purple flowers, standing out from vertical rocks; and the latter, with its white, starry flowers, creeping close to the surface of the rocks over which it grows. *Veronica Teucrium dubia* and *V. orientalis* make low carpets of deep blue, while the yellow *Achillea tomentosa* forms a suitable companion to the white-flowering species *A. Oeristii* and *A. Huteri*. *Antirrhinum glutinosum* and *Helichrysum bellidioides* are excellent June-flowering subjects. Both creep among the rocks, and when overhanging a boulder are never so happy. Sun Roses, Rock Roses and Saxifrages each contribute to the floral beauty of the rock garden in June; and while space does not permit the mention of others, reference must at least be made to *Saxifraga pyramidalis*, with erect sprays of bloom 1 foot to 4 feet long. It is appropriately known as the Queen of the Saxifrages.

A JUNE SCENE IN A BEAUTIFUL ROCK GARDEN.

moderate gale need no more than a strand of stout string, while a larger number than one would think are best left to themselves. All the border Lilies, such as *Martagons*, *tigrinus*, *excelsum*, *croceum*, *candidum*, *pardalinum* and *chalcodonicum*, need no support. Many composites growing in old masses ask for support, which, when grown in single-stemmed pieces, planted annually, are vastly better left to themselves. None of the large family of decorative *Aconitums*, nor the *Senecios*, nor *Astilbe*, nor *Bocconia* need be staked. Some may not grow quite upright, but that is not in the way of a fault. How horrid it is to see such a distinctly beautiful plant from base to summit as a Japanese *Anemone* subjected to the indignity of stick and tie, even if the support be green-painted, varnished and finished in gold! It is worth notice, too, that seedlings of certain plants, such, for instance, as *Delphiniums* and *Lupinus polyphyllus* in variety, that must be staked when old, need no support.

and at the same time promote the production of more flowers over a longer period. *Lupinus polyphyllus* and its hybrids also produce spikes in long succession if the precaution of removing the older spikes before they are flowered out be taken. It is too long to leave them till the seed-pods are being filled and all the flowers on a spike are withered. To be successful with many of our border flowers, one must be a little bit removed from timidity. Thin where necessary, prune with an eye to the future as well as the present, and never delay easing a plant that is worthy of it of flowers, either in spikes or otherwise, even though their removal may for a few days slightly lower their decorative value. Such a free-seeding plant as the bedding *Viola* should frequently be picked over, removing every old bloom, whether withered or approaching that condition. This will ensure a long extended period of flowering.

Prestonkirk, N.B.

R. P. BROTHERSTON.

THE COLLARETTE DAHLIAS.

IT is time to plant out Dahlias, and to those who have wearied of the stiff and heavy show varieties, the new Collarette type specially appeals. This is a distinctive type of single Dahlia, having an inner circle of small florets issuing from the base of the yellow central disc, and edged on the outside with petals of every shade of colour and form. It is altogether an advance on anything hitherto seen. The flowers are borne on long stalks well above the foliage, and are most useful for decorative purposes, lasting, when cut, a full week in water in a cool room, while their long stalks add to their usefulness and charm.

Freedom of Flowering.—From all those who have grown these Collarette Dahlias one hears nothing but praise. It seems exaggeration to speak of them as "perpetual flowering," yet such was the fact last autumn. For two months they were a constant source of floral wealth, and the beds were radiant with flowers when all else save Michaelmas Daisies had lived their span. Until cut down by frost they can be relied upon to yield a profusion of blossom; hence their value either in separate beds or in clumps in the herbaceous border.

Culture.—The culture needed does not differ from that required by all Dahlias, which revel in a rather heavy, clayey loam, thoroughly well worked. Whether the soil be heavy or light, deep cultivation is necessary, and thus ensures proper drainage. A liberal supply of well-decayed manure should also be worked into the soil, and if this has been done in the autumn, so much the better. However, if the Dahlias are to be planted in the border, this may not have been possible. Take, therefore, the site chosen, dig a fairly large hole, and well mix the manure with the bottom soil before planting. Dahlias rarely get over-manured.

Situation and Planting.—Being bushy in form, moderate in height and requiring only the support afforded by ordinary thin canes, the Collarette Dahlia is suited for any position, flowering profusely between shrubs or disporting itself in lonely grandeur in circular beds on lawns, while it is most useful in the herbaceous borders, forming a blaze of colour in late autumn when flowers are scarce. It is advisable to buy plants (knocked out of pots) direct from one or other of the firms that have specialised in this new type. Most, or all, of the firms who specialise in Dahlias now list them, so that there should be no difficulty in obtaining plants. Turn the plant out of the pot, taking care to preserve the ball of

soil intact, place it in the prepared hole, and tie it to the cane (already in position) with a piece of raffia. The after-attention required is very little. Add more canes as needed, and tie in the growths. Slugs and insects—the usual pests—must be expected and destroyed at the onset, and then the grower may feel confident of a harvest of flowers until cruel King Frost casts his withering hand around.

Varieties.—The following half-dozen have been proved of sterling worth and can be recommended, but others can be selected from the raisers' catalogues to suit individual taste. None of them is very expensive to purchase.

Balmoral.—A puce colour with a white collarette. A good grower and very free flowering.

AN EFFECTIVE GROUPING OF SAPONARIA OCYMOIDES, A BEAUTIFUL PLANT FOR THE ROCK GARDEN.

Queen Bess.—A scarlet with yellow collarette.

Frogmore.—The finest I know. Yellow and vermillion, with a yellow collarette. This leaves nothing to be desired in form and colour, while it is very vigorous and a perpetual bloomer.

Princess Louise.—A rich crimson flower with broad petals and white collarette.

Negro.—A maroon with white collarette. Is of lovely form and colour; very free and effective. Probably the best word to describe

Henri Farman, a bright vermillion edged with primrose, with straw collarette, is "grand"—the word used by everyone on beholding a newly opened flower of this variety. S. M. C.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

THE FINAL POTTING OF THE PLANTS.

BEFORE June ends, the whole of the plants must be placed in their flowering pots, not only those intended for flowering in October and November for exhibition purposes and the furnishing of the conservatory, but also those that are to yield flowers in December and at Christmas. There are several points in connection with the treatment of late-flowering varieties that amateur cultivators ought to carefully note. One is the advisability of getting the plants well established in their large pots in good time, as we should remember that feeding at will can be done later on. Another important point is the stopping of the shoots also in due time. It is a great mistake to stop the shoots late, as very frequently the resultant blooms are entirely lacking in substance. Often I have seen them with two or three rows of petals on one side of the opening buds only.

The Final Potting is regarded by some cultivators as the principal one, and also the chief thing that can be done in regard to the treatment of the plants. That it is important I admit, but really not more so than the previous repottings, as, unless the work in connection with them is equally well carried out, poor plants would result now, and no amount of care in doing the final potting would convert them into splendid specimens. In carrying out the work, care should be taken to ensure sound drainage, clean crocks and pots both inside and outside, a well-mixed compost and pots of suitable size. Weakly growing varieties should be potted in 9-inch pots, and stronger growers in 10½-inch ones. If larger pots are used, place two plants in each, and take on two main stems on each plant if they are being grown for the production of exhibition blooms—four blooms to a pot instead of the orthodox three. By following this

plan the general health of the whole collection will be maintained at a high standard.

The Soil.—Fibrous loam must form the bulk of the compost. If the loam is rather heavy, use more leaf-soil and sand in it than if it is of a light nature. A pint of bone-meal to a bushel of the compost, a 6-inch potful of soot and a similar quantity of wood-ashes to the bushel, with a good concentrated chemical dressing according to the directions given with it, should complete the compost for the final potting. Do not ram the soil very firmly; there is the medium course, and this is best, taking the potting of the whole collection of incurved, Japanese and single-flowered sections respectively. The wood may be too

hard. There is only a given time for the growth of the plants, and if the stopping or the natural breaks are right, the growths made afterwards will mature sufficiently. Put in some of the coarser parts on the crocks, and use the remainder in due proportion to the small. Leave space at the top for top-dressings, watering and feeding. A 2-inch space will be sufficient, and nearly the whole of this will be filled by light top mulches applied every ten days after the end of July, or the third week or so in that month. After potting, space out the plants in rows north and south if convenient, and place the stakes to them. If the weather proves bright and dry, syringe the plants twice every day, and be careful not to overwater the soil; then new roots will permeate it very soon.

AVON.

SEASONABLE NOTES ON VEGETABLES.

Celery.—Plant firmly in well-prepared trenches, lifting the plants carefully with a good ball of soil attached to the roots of each. Failing showers, keep them well watered in the trenches, and dust the plants occasionally with soot as a preventive of the Celery fly.

Asparagus.—Continue to cut evenly over the beds until the end of this month. Thoroughly soak the beds occasionally with liquid manure, which not only improves the present "grass," but assists the plants for next season's crop. If in an exposed position, secure the strongest plants by pieces of string on each side of the bed to prevent them being broken by wind. A few short Pea stakes thrust in among the plants will provide useful supports.

Cucumbers in Frames will now need careful attention, especially if they have been fruiting some time, and will require stimulating for future crops. Prune rather severely any growth that has borne freely. This cutting away of old haulm and leaves will provide more light and encourage new growth, especially if the plants receive a good soaking of liquid manure and a mulching, 2 inches thick, of partly decayed manure, leaf-mould or fresh loam, adding a handful of soot. This will encourage the growth of surface roots. Keep the frame somewhat closer for a time, closing it early in the afternoon with plenty of sun-heat, first sprinkling the foliage with tepid water. Pinch out the point of each new shoot above the second leaf, and if fruits show freely, thin these for the benefit of the plants in the future, as too many plants are ruined by overcropping.

Ridge Cucumbers must have attention. Those previously raised in pots should be

planted out on a heap of litter and leaves, with a surfacing of old potting soil, encouraging the growth by the aid of hand-lights, or even pieces of glass laid over bricks. Sow seeds where the plants are to fruit for a succession. Mulch the surface to encourage freedom of growth.

Radishes require much attention to maintain a regular succession of succulent roots. Small weekly sowings are better than sowing at longer intervals. Nothing is finer than the French Breakfast type for flavour or quick growth. During dry weather well soak the soil before sowing the seed. Afterwards apply a light shading until the plants are

of growth, which will be found an advantage next year.

Peas.—Continue to sow late sorts like The Gladstone, Goldfinder, Late Queen and Ne Plus Ultra in previously watered drills. Well soak and mulch all plants growing in rows. Where extra fine pods are required, thin judiciously, and top the haulm when a sufficient crop is assured. Stake early to encourage upright and robust growth, and do not forget that the more moisture that can be given to the roots, especially liquid manure, the better will be the result.

Runner Beans now growing freely should have attention. Train the haulm thinly up the stakes, removing surplus lateral growth. Water well, syringe in the evening, and mulch between the rows.

Lettuce should be often sown. On the Celery ridges is an economical method. Water the drill before sowing. Directly the plants are large enough to handle, thin out and transplant, thus having an equivalent to two sowings. Moisture at the root and overhead in abundance is the only secret in obtaining succulent Lettuce.

Onions need attention in their various stages. The Rocca and Leviathan types should not be overfed yet, lest too many plants run to seed. Keep a sharp look-out on all batches for mildew. Dust with wood-ashes and soot as a preventive. The outdoor-sown batch will require thinning where large bulbs are required; but for ordinary use and for pickling no thinning is required, especially if thick sowing has been avoided. Keep the hoe busily employed between the rows.

E. MOLYNEUX.

Sawmire, Hants.

THE RARE AND BEAUTIFUL IRIS LÆVIGATA ALBA. A WHITE-FLOWERED FORM OF A LITTLE KNOWN SPECIES.

IRIS LÆVIGATA ALBA.

It was recently our good fortune to see, for the first time, this rare and beautiful Iris flowering in the vast collection of Irises in Messrs. R. Wallace and Co's nursery at Colchester. The flowers are clear ivory white, with a faint shading of mauve at the throat. Growing about two feet or less in height, it is a variety that at once arrests attention by virtue of the purity and refinement of

the flowers. It was not surprising that it should have been granted an award of merit by the Royal Horticultural Society at a recent meeting. It should be pointed out that it is quite distinct from the lævigata alba of gardens, which is really a variety of sibirica orientalis. Neither must lævigata (true) be confused with the species Kämpferi, from which in foliage and form of flower it is quite distinct. Unfortunately much confusion still exists between Iris lævigata and I. Kämpferi. That they are distinct in flower and foliage may be seen from the illustration of the white-flowered form of the typical I. lævigata.

above the surface. Sprinkle them in the evening for preference.

Turnips are a difficult crop to manage during a spell of drought. Choose a shady place; a north border, for example. Water the soil before sowing, and, as soon as the plants appear above the soil, dust them over with soot and wood-ashes. Thin out the plants early.

Rhubarb should receive encouragement for its welfare next year by the prompt removal of seed-stems, and be given a thick mulching of partly decayed manure, the juices of which will benefit the roots and encourage freedom

of growth. It was not surprising that it should have been granted an award of merit by the Royal Horticultural Society at a recent meeting. It should be pointed out that it is quite distinct from the lævigata alba of gardens, which is really a variety of sibirica orientalis. Neither must lævigata (true) be confused with the species Kämpferi, from which in foliage and form of flower it is quite distinct. Unfortunately much confusion still exists between Iris lævigata and I. Kämpferi. That they are distinct in flower and foliage may be seen from the illustration of the white-flowered form of the typical I. lævigata.

GARDENING FOR BEGINNERS.

HOW TO GROW CELERY AND LEEKS.

AS both of these popular vegetables thrive best in a deep, friable loam, the cultivators who possess such have a great advantage over others who have to deal with a stiff, adhesive loam which can only be satisfactorily worked a few hours after a shower of rain, and which pans down very hard if worked while in a very moist condition. Cultivators will now turn their attention to the planting of Celery and Leeks, and look for their reward next autumn and winter. Trenches may have already been made and manured ready for the plants. If the soil in the bottom of the trench is found to be set hard, dig it and break up any lumps before putting out any plants. I have found it a capital plan to gather up some old potting soil, road

enough. The top soil removed should be placed on one side, and the spit below it on the other side. Then return the good soil and the manure, and thoroughly mix both before putting in the plants.

The Plants and Planting.—Dwarf, sturdy plants possessing plenty of roots, such as shown at No. 1, Fig. A, are the best if from 5 inches to 9 inches in height. Very tall, weakly specimens with few roots, resembling No. 2, are not good ones. They receive a severe check when disturbed, and do not recover for a long time after planting in the trenches; in fact, nearly all the tallest leaf-stalks perish. No. 3 denotes a fine transplanted Leek, and No. 4 a poor one as drawn from the seed-bed. Single rows of both Celery and Leeks should be planted as denoted by the crosses, No. 1 in Fig. B, and double rows of the former in zigzag fashion 10 inches apart, as shown by the small circles, No. 2. No. 3 also shows them in the trench with neat ridges, Nos. 4, 4, on which temporary crops, such as Lettuces or Dwarf Beans, may be grown. A sectional view of the Leeks and trench is shown in Fig. C. These plants are gross feeders, and so plenty of rotted manure should be mixed with the soil quite a foot deep for the roots to make a good start in, as shown at No. 1, No. 2 being undisturbed soil. In every case water thoroughly, and maintain the soil in a moist condition. It is also beneficial to the plants if a surface mulch of loam, leaf-soil and manure is put on an inch deep at the time of planting.

G. G.

A VIOLA FOR THE ROCK GARDEN.

ONE of the most brilliant of our new rock garden Violas is the variety we call Solitude. It is of the *gracilis grandeur* class, and has a very dwarf, neat habit, with small, pointed leaves, and carries its hordes of blossoms well erect upon sturdy foot-stalks. It is long in blossom, having been in flower throughout March, April and May, and is still as full as ever without any attention, and promises to go on for a considerable time. It will be noted that, belonging to the improved *grandeur* type, the new-comer will prove of the utmost value for rock garden work, also for bedding, as few Violas flower like this section, and none retains so well as these that splendid dwarf habit which is such a tremendous asset in their favour. But, after all, it is the colour of Solitude that tells—a deep mountain blue, rich and unsullied, that carries one in thought at once to the clear skies and the distant blue of the high hills. The appealing intensity of Solitude is very real, and if we can get it on the slopes it will attract more than *gracilis* or *grandeur*, or, indeed, to my mind, more than any other blue Viola. Its name Solitude was born of the mountain blue of its colouring, unusual in its serene beauty.

P. S. HAYWARD.

SHIRLEY POPPIES AS CUT FLOWERS.

WHEN inspecting the various exhibits at flower shows, one has frequently been both sorry and surprised at the comparatively small number of competitors in classes for the beautiful Shirley Poppies—of such easy cultivation, and for whose

THE METHODS OF PLANTING SINGLE AND DOUBLE ROWS IN A TRENCH ARE SHOWN HERE.

introduction we all owe a debt of gratitude to the Rev. W. Wilks, the able hon. secretary of the Royal Horticultural Society—the obvious deduction being that this pretty annual is not so much grown, or if grown, cut and used, as it deserves to be. The reason lies probably in the fact that the cut blooms do not, in the ordinary way, last well in water, owing to the “bleeding” process which ensues; hence their apparent comparative unpopularity. This disadvantage can, however, fortunately be remedied with a minimum of trouble if, immediately after cutting, the stalks be immersed in half an inch of boiling water for two minutes, then placed ordinarily in cold water. It is best, of course, to cut the blooms before they are fully expanded, and a method of assistance in this direction is to crack the outside covering of all vertical buds the previous evening; this ensures having young blooms next day. By the practice of the above plan the erroneous—yet common—impression that Shirley Poppies cannot be made to last will be dispelled, for they will then keep several days, while, incidentally, their decorative value will be increased. This is the method I have always adopted when exhibiting Poppies, with successful results.

B. W. LEWIS.

SECTIONAL VIEW OF A WELL-MANURED TRENCH, SHOWING THE YOUNG LEEKS PLANTED.

DIAGRAMS TO REPRESENT GOOD AND BAD PLANTS OF CELERY AND LEEKS AT PLANTING-TIME.

scrapings from roads not frequented by motor-cars, sifted leaf-soil and material from the surface of old hot-beds, and, having scattered the mixture in the trench, dig it in and so provide a suitable rooting medium for the young plants.

About Trenches.—I am quite sure that cultivators make their trenches too deep. The best soil—that about sixteen inches from the top—is taken out and placed so as to form ridges between the trenches. Manure is then put in, and the plants in it and the cold subsoil. The good soil taken out is used mainly for earthing-up—blanching purposes. Some cultivators do return a portion of the good soil before the plants are put out. The cultivator should be guided a good deal by the depth of rich soil he possesses as to the matter of trench-making; but even in the case of very good, deep soil, the trench should not be deeper than 18 inches before manure is put in. In poor, shallow soils 9 inches is deep

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Grape Lady Downe's.—The final thinning of these Grapes should be accomplished as soon as possible. Remove all seedless berries, and allow sufficient space for the berries that remain to grow to their full size without coming in contact with each other. Examine the border, and if necessary give a good soaking of weak liquid manure, after which the ventilators should be left slightly open during the night. As the season advances, the ventilators should be opened early in the morning with a view to clearing off condensed moisture.

Tomatoes.—Plants which have set a full crop may have their tops pinched out, and should be assisted with some stimulant; either liquid manure from the farmyard or Peruvian Guano washed into the soil will suit them well. Keep the side shoots pinched off, and if the foliage becomes too strong, some part of it may be removed. Plants for succession may be potted into their fruiting pots and grown in some well-ventilated structure where air can be admitted night and day. If house room is not available, these plants will set their crop quite well in the open if staked and secured to a wire in the same manner as Chrysanthemums. Pot moderately firmly in good turfy loam, and place a few half-inch bones over the corks.

Plants Under Glass.

Spring-Struck Plants of *Dracæna*, *Croton*, *Pandanus* and *Begonia* should all be potted up as soon as ready and grown in a temperature of 75°. Keep a watch for insect pests, which must be destroyed as soon as they appear, or the plants may soon become deformed in consequence.

Cinerarias.—If seeds were sown in April, the plants will now be ready for potting into 4-inch pots. They should be grown in a cold pit facing north, and protected from strong sun when they become established in the fresh soil.

Chinese Primulas.—The early batch of these should now be ready for potting into 4-inch pots. These plants succeed best when grown in a cold pit on a bed of ashes until the autumn, when they should be removed to a cool, well-ventilated house within a foot of the roof glass. During the summer Primulas will benefit by exposure to night air, and the lights may be removed with advantage during warm evenings, but not during heavy rain. Primula seeds may still be sown to produce plants for spring flowering.

The Flower Garden.

Watering.—If the weather is dry, constant attention should be given to recently planted subjects, for, if allowed to suffer from want of moisture at the roots, no amount of care afterwards will restore them to their natural beauty. After watering has been thoroughly accomplished, the soil between the plants should be carefully hoed, and this will act as a mulching to the roots. In places where a mulching of horse-manure can be applied, this will be of great advantage to the plants; but before this is applied it should be placed together for fermentation and allowed to remain for a few days. Plants in vases with restricted root space and full exposure to sun and wind should receive daily attention in this respect, or many of them may cast their leaves and become unsightly.

Spring Bedding Plants.—Wallflowers, Polyanthuses and other plants intended for spring bedding should be transplanted from the seed-beds to a convenient plot, in order to produce good, stocky plants when the time arrives. Allow sufficient space between the plants to admit plenty of light and air, and do not allow them to suffer from want of water during the summer.

The Hardy Fruit Garden.

Raspberries.—Plants which are swelling their fruits will benefit by a good soaking of manure-water, and, if not already done, the bed should be mulched with farmyard manure. Suckers which are not required for next season's crop or for autumn planting may be removed, in order to admit sun and air among the plants. As soon as the fruits begin to colour, the bed should be carefully netted to protect them from birds,

Strawberries.—Late batches of Strawberries should receive an abundant supply of water at the roots, in order to swell the fruits. If once the plants are allowed to suffer from want of water, the prospect of a satisfactory crop will be much reduced. Net the plants as soon as the fruits begin to colour.

Wall Trees.—The leading shoots which are necessary for extension should be carefully tied or nailed in the direction they are required, but no general stopping of the growth should take place for another month. Apricots which are planted on well-drained borders must receive a plentiful supply of water at the roots. Examine the trees for maggots, which should be destroyed at once. Peach trees ought to be syringed early in the afternoons, and if there are signs of red spider or other pests, a little Quassia Extract may be mixed with the water constantly to keep them in check. The final thinning of the fruits should take place as soon as possible, leaving the best-placed fruits and nothing beyond a fair crop.

The Kitchen Garden.

French Beans.—Frequent small sowings should be made in the open garden, choosing ground which has been trenched during the winter. As growth advances, a mulching of decayed manure will be of great benefit to them, especially if the weather is dry.

Carrots.—A sowing of Stump-rooted Carrots may now be made for use in the winter and spring. If the soil is dry, the drills should be watered freely in the evening and the seeds sown the following morning. If a crust has been formed by the water, this should be slightly disturbed before the seeds are sown.

Spinach.—This is an important summer crop, and requires a good deal of attention during dry weather. At Frogmore we sow weekly in cold pits during the summer, and water freely every day. By this means we keep up a constant supply of green leaves through the summer.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Asparagus.—In most cases it will not be wise to cut after this date, although I have known several gardens where cutting was continued until the beginning of July. These cases, however, are exceptional; indeed, if the beds are not in a very good state, it would be better to stop even much earlier than the middle of June. It must be remembered that next season's crowns have to be formed by the present year's growth. When cutting ceases and the young growths come away, care should be taken that these are not shaken by strong winds, otherwise the stems break off at the base, which will weaken the crown. To prevent this, they should be supported with small stakes and connected with tarred string.

Dwarf Beans.—A sowing made out of doors now will for all practical purposes be sufficient to last the season. Should the ground be dry and there be no immediate sign of rain, it will be advisable to soak the seeds in water for several hours before sowing, and if the weather continues dry, they will be all the better for an occasional watering. For this crop thin out the plants to about a foot apart.

Peas.—In many districts it will not be safe to sow after this date, at least in the open, and even a sowing made now may to a large extent be precarious. For the most part I advise sowing early varieties for late cropping; still, I was much impressed a year ago with a very fine crop of Peas quite late in the season, which I was informed was Chelsonian, and it seems it can always be relied on. Seeds sown now should be soaked in water for an hour or two previously. Avoid thick sowing, which would assuredly encourage attacks from mildew.

The Flower Garden.

Dahlias.—These will now have got nicely started away in their flowering quarters, and every care should be taken to hasten them on till the flowering stage. As it is scarcely possible to overfeed them, a little short farmyard manure spread over the surface will be very beneficial. Their season, as a rule, is all too short, and should

their growth be retarded by any neglect, it is just possible they may be cut down by frost before they come into bloom. It must be remembered that earwigs are particularly fond of Dahlias, and every means should be taken to have them trapped. This is best done by placing a little dry moss in a small pot and putting it inverted on the stake. The pots must be examined morning and evening and the earwigs destroyed. Do not wait until they have done some damage, but commence trapping at once.

Flowering Shrubs.—A great many of these will have passed out of flower, and any pruning that is necessary should be done forthwith. In doing so, first cut away all decayed and sickly branches, and afterwards cut back the strongest shoots, so that when completed the shrub will have the appearance of a renewed lease of life.

Plants Under Glass.

Winter Stocks.—A start should now be made by sowing a small quantity of seed of these delightful winter and early spring flowering plants. The seeds may be sown either in small pots or boxes, and placed in a cold frame and brought on very quietly. Successive sowings can be made till the end of July. The Stocks most suitable for this work are the Beauty of Nice type and that lovely lavender Emperor, Augusta Victoria. During the past season we had a house devoted to them, and they were a sight not readily to be forgotten. Many of the spikes were over two feet in length. I find they travel well and last a long time in a cut state.

Coleus thyrsoides.—This striking greenhouse plant is fast becoming popular, partly from the fact that it possesses flowers of a clear blue shade, a shade which is very much in evidence at the moment. The plant itself, however, is handsome, and, blooming as it does in the winter, it has an additional attraction. Cuttings should be inserted at once, and, like other members of this family, they root quickly. After being potted on they ought to be pinched at least twice to form nice bushy plants. Keep them growing on in a moderate temperature where they will have plenty of light and air.

Solanums.—These one-time favourite fruiting plants will now be ready for their final potting, and in doing so see that the soil is moderately rich. For obvious reasons the pot should not exceed 6 inches or 7 inches in diameter. In favoured districts these plants may be grown outside during the summer months, but in colder districts better results will be obtained by growing them in frames.

The Hardy Fruit Garden.

Protecting Strawberries.—If this has not been done, no time should be lost in having the nets put over the various plantations. This work is often delayed too long, on the plea that the fruits are not yet colouring. My experience is that the birds often attack them before they get to that stage, and it is much more difficult to keep the birds out after they have had a taste than it would have been had the fruits been protected earlier.

Raspberries.—These should receive a heavy mulching at once if this has not been already done. Before doing so, clear the ground of weeds, and thin out the suckers where they appear too close.

Fruits Under Glass.

Peaches.—In houses where the fruit is colouring a drier atmosphere should be maintained, and to enable the fruit to be well coloured all round, it will be necessary to put the leaves aside; indeed, if time permitted, each fruit should be turned up to the light by placing a small piece of lath under it. In the earliest houses where the fruit has been gathered, the trees should be heavily syringed to keep the foliage healthy, and see that the border is in a moist condition.

Vine Madresfield Court.—Water should never be given to the border until it has been previously tested. This should, of course, apply to all fruit borders under glass, but more particularly to those containing this fine variety. If the border is too wet, the berries will be liable to split; this usually occurs just before they commence to colour. Another cause of splitting is the berries being too tightly packed. In any case where splitting is observed, keep a free circulation of air night and day.

BOOKS.

The Ethics of Rebuilding.*—Mr. Weaver, in the prefatory note to this volume, writes: "The welcome given to 'Small Country Houses of To-day' would seem, if I may believe my correspondents, to have been due in no small measure to chapters which described old houses repaired and enlarged. This suggested that a second and uniform volume, dealing wholly with the treatment of old houses, whether cottage or farm, house or small manor house, would be useful to the increasing number of people who like the atmosphere of age in their homes." The author's previous volume in the same series was a deserved success, and we believe this book will be accorded a welcome at least as great as that enjoyed by its predecessor. The many difficulties which are inherent in the repair and enlargement of an old house are very thoroughly dealt with in this book, which shows how forty houses of five centuries have been given a new lease of life. Detailed descriptions reveal how they have been re-equipped as modern needs demand, without destroying the witness they bear to the old traditions of building. Incidentally the author has shown in how many cases the records of modest little houses have been preserved and how intimately their local story is woven into the larger fabric of national history. To all who contemplate the alteration of an old house and desire to achieve it in the right spirit, this book will be an indispensable guide.

My Garden in Summer.†—Mr. Bowles in "My Garden in Summer" has written a book more interesting even than "My Garden in Spring," captivating though that is. The writing throughout is brisk and breezy, while it is replete with amusing passages which make it the more piquant. One which has "fetched" us is the following: "The Hawthorias, with their starry rosettes, look as if sprinkled over with pearls or a carefully picked out handful of white hundreds and thousands, which could only have been the work of the little girl who produced a farthing in the sweet-shop, saying, 'A farthing's worth of hundreds and thousands, and please pick out all pink ones.'" Mr. Bowles tells his readers of plants which many of them may never have heard of, and accordingly whets their desire to grow them. It is rather a surprise to us to find the author, who does not as a rule shrink from expressing his opinion about many plants, writing favourably of Rose Rayon d'Or. We admit it has perfect mildew-proof foliage and bears some beautiful flowers; but for how long can it be grown? Our experience of it is that when it does not die outright the first

season after planting, it dies by early instalments. We are glad to see that Mr. Bowles has so high an opinion of Rosa Moyesii—too seldom seen in gardens—a good doer, practically evergreen, and a veritable glory throughout June. By the by, we know of no hybrid raised from it yet. On pages 72 and 73 Mr. Bowles tells his readers of the lovely Roses he saw in bloom at Modane last year. What a pity he did not mark them then and pay the spot a visit in lifting-time! His garden would have been the richer for it, and so would some of ours, as Mr. Bowles is the very soul of generosity. In reading the book one almost feels one's self walking round the author's garden with him, so realistically is it written. Mr. Bowles is undoubtedly ever open-eyed and a keen observer of everything, whether it be a plant, an insect, or a bird. He is enthusiastic of Mont Cenis and its neighbourhood, as well he might be, for we know of no place more beautiful or more interesting from a plant point of view. Many who read this book will feel as we do—that we

either. The only reason why production continues must be on account of new cultivators joining the ranks of specialists, and to these the new writers who from time to time emerge into the public gaze make a strong, if not an overpowering appeal. It is to these, the extreme tyros, that the present volume devotes its fifty-five beautifully printed pages of Carnation lore. From the simplicity of the style and the unconnected grouping of the various items, one would not have been surprised to learn that the author had been keeping in view the horticultural schoolboy. And the very simplicity aimed at has been the means of leading him astray on more than one occasion; but that perhaps is rather on account of book composition being less in his way than the production of the sweetest of sweet flowers. One cannot judge of the utility of a book like this just because of these obvious facts—facts that stare one in the face in perusing the book. The teaching is in general to be commended, though why cuttings properly treated should require so long a time as six weeks

to become rooted is not very clear. [Other cultural items as well as the remarks on cutting and preserving the blooms when cut are to the point. Like other growers, Mr. Wootten has his special compost, which contains as much as one-third rotted stable manure to the loam. I should tremble for the future of Carnations given manure in these proportions; but perhaps the 3-inch potful of charcoal to the eight bushels of soil and manure is intended as a mild corrective. The timing of the blooming season by means of stopping is becoming an absorbing question, which the author leads one to expect to see solved in the list of varieties appended, but one is disappointed to find nothing of the kind when reference is made to the list. This is a serious omission. The volume is illustrated, showing blooms of

many Carnations, is nicely bound in art linen, and the printing is clear and good.—R. P. B.

PRELIMINARY REPORT ON THE WORK OF THE TULIP NOMENCLATURE COMMITTEE.

IN the autumn of 1913 an invitation was issued by the Royal Horticultural Society to the leading growers to send to Wisley for trial bulbs of their varieties of Tulips, with the names under which they respectively knew them. These were planted at Wisley, and on Monday, April 20, a joint committee of Dutch and English experts met to consider the early varieties, and again on May 6 and 7 to consider the May-flowering varieties. The committee consists of Mr. E. A. Bowles, M.A. (chairman), Mr. Krelage (vice-chairman), the Rev. Joseph Jacob, and Messrs. Barr, de Graaff, Hall, Hoog, Leak, Needham, Roes and Ware. Over four thousand varieties were examined,

A THATCHED SHELTER AT MR. F. E. SMITH'S HOUSE.

must alter our gardens and make them more like the author's. A persual of "My Garden in Summer" cannot fail to teach readers much they did not know before. It is apparently written with a good-natured desire to help them, and not with a superior didactic air we have met with in other books. From beginning to end "My Garden in Summer" is a book of kindness—characteristic of the author. It is charmingly written, original and full of information, while there is not a passage in it to which the most sensitive person can take exception. In a word, it is a book we cordially recommend to every horticulturist.

Perpetual-Flowering Carnations.*—Books on Carnations are becoming as plentiful as those on Sweet Peas, two flowers which are so easy to grow that it would be expecting too much to look for anything novel in a new volume on

* "Small Country Houses: Their Repair and Enlargement," by Lawrence Weaver. Country Life Library; 15s. net.

† "My Garden in Summer," by E. A. Bowles. London: E. and T. C. Jack; price 5s. net.

* "The Perpetual Carnation and How to Grow It Indoors and Out of Doors," by E. J. Wootten, Carnation Specialist. Manchester: Warren and Son, Limited. London: Simpkin and Co., Limited. Price 3s. net.

and their nomenclature and synonyms determined. The trials of the May-flowering varieties only will be continued in 1915, and growers are invited to send fresh bulbs—five of each variety—named. Bulbs will not be accepted later than November 1, 1914. Senders are asked to roughly designate their colour and the class to which they belong to facilitate the work of planting.

On each occasion the committee sat in conference and drew up recommendations for a classification. These will be reconsidered at a conference to be held at Vincent Square on May 13 and 14, 1915. It is then intended to prepare the final list of varieties and synonyms, and all recommended varieties will be definitely placed in one or other of the sections and subsections of the classification. This final list, with official descriptions, will be printed and published by, and at the expense of, the Royal Horticultural Society in conjunction with the Dutch Bulb Growers' Society in Haarlem. To make the descriptions short and clear, certain typical varieties will be selected, described, figured and named, so that others can be described by reference to them. Thus systematised, the colour, shape, base, and the relative length and breadth of the inner segments will be recorded.

The Council have adopted the recommendation of the committee to hold a show of Darwin and Cottage Tulips on May 14, 1915, for cut blooms only, in vases, for the purpose of enabling the Nomenclature Committee to decide on the synonyms of the varieties sent.

PRUNING DECIDUOUS FLOWERING SHRUBS.

THE correct pruning of many flowering shrubs has a great deal to do with their success or failure in our gardens. It may mean—in fact, it usually does mean—the difference between a most attractive border of flowering shrubs and just an ordinary border of shrubs serving as a screen with no particular beauty. Broadly speaking, flowering shrubs can be divided into two great groups, namely, those which flower during the spring and early summer, and those which produce their blossoms in late summer and autumn, which, if any pruning is required, should be attended to in early spring.

At present we are concerned with the first-named group, which includes the *Philadelphus*, *Ribes*, shrubby *Prunus*, the early-flowering *Spiræas*, *Deutzias*, *Forsythias*, *Kerrias* and *Diervillas*. The term "pruning" here is intended to include also the cutting out of old, useless wood and the thinning of the growths to admit air and light into the bushes, thus ripening the shoots, which will improve their floriferous character. At the same time, the shape of the bushes may be considered, taking off a long piece here and shortening a shoot elsewhere to maintain them as shapely specimens. The time to do this work is as soon as convenient after the flowers fade. This enables the plant to make ample new growth for the sun and air to ripen before the dull days of winter. It is quite impossible here to give any hard-and-fast rules respecting the amount of pruning necessary. Individual requirements vary so much, and the position the plants occupy in the garden may also need consideration. Some kinds flower more freely when pruned fairly

hard. These include *Forsythias*, *Prunus triloba* flore pleno, *P. sinensis* flore pleno and *Philadelphus Lemoinei* erectus. With another group, notably *Deutzias*, *Kerrias* and *Spiræa van Houttei*, it usually pays to cut the older growths entirely down to the ground, leaving the remainder to develop their full length. Other bushes are improved by cutting the ends of the flowering branches back to where young shoots are pushing out, also cutting out a few long growths when too thick. Instances of this treatment are *Philadelphus coronarius*, *Spiræa arguta*, *S. prunifolia* flore pleno, and *Diervillas*.

At the present time the Lilac bushes, admittedly one of our most beautiful flowering shrubs, require attention. All the old faded flowers should be cut off, and at the same time thin out the quantities of young shoots which are growing rapidly. Treatment such as this, in reducing the number of growths, admits more sun and air to the bushes, with the consequent development of much better flowering wood for next season's display of blossoms. Another matter which may have attention at the present time is the mulching of deciduous flowering shrubs with well-decayed manure, also watering if the weather is dry. Should the manure be considered objectionable, there is the alternative of watering liberally several times with liquid manure. A. O.

WILD FLOWERS FOR THE GARDEN.

WHEN thinking of wild flowers for the garden we should on no account forget the Woodruff. If there is a damp, shady place where little will grow, the Woodruff will cheerfully spread over and lighten it with its tufts of bright green leaves and snowy white flowers. The Trollius, or Globe Flower, is a fine, handsome summer plant and worthy of a place in any garden. If annuals are wanted, then why not try a collection of British Poppies? One cannot, of course, get the great diversity of colouring as in Shirley Poppies, but collecting the seeds of the different kinds, the Pale Poppy, the Round Rough-headed Poppy, the Long Smooth-headed Poppy, the Opium Poppy, and so on, will be a work of great interest. Then there are the Crane's-bills. They deserve to be represented in every garden. First, one might have the Dusky Crane's-bill (*Geranium Phæum*), flowering in May and June; then, in sharp contrast, the beautiful bright blue Meadow Crane's-bill (*Geranium pratense*), and the Bloody Crane's-bill (*G. sanguineum*), with large purple flowers and deeply cut leaves. A place should be found, too, for the common purple Foxglove, though, unless there is some bare spot where it can spread at will, it must be kept carefully within bounds. Another plant to have in small quantities is the Borage, also its two cousins, the Viper's Bugloss (*Echium vulgare*) and Alkanet (*Anchusa officinalis*), all three of which have bright blue flowers. If there is a wall to be considered, plant Red Spur Valerian (*Centranthus ruber*) in the crannies. Once it gets a firm hold, it spreads quickly and flowers on from June to September. The Rose Bay (*Epilobium angustifolium*) should on no account be forgotten. It makes a splendid show if given a rather damp position, but here again it must be kept in order, or it will choke everything else. One must not linger too long over the summer

flowers, attractive though they are. The early autumn is very well supplied with blossom, too. All the different Campanulas or Bellflowers are well worth growing, and so is the beautiful blue Chicory (*Cichorium Intybus*), which will go on until it gets nipped by the frosts of October. There are two bulbous plants for the autumn which one ought to find room for—the Meadow Saffron (*Colchicum autumnale*) and *Scilla autumnalis*, or Autumnal Squill. The first named is very like a Crocus, with flowers of an indescribable shade between pink and purple. It is not common, but grows freely where it is established. One peculiarity about it is that its leaves and seed-pods do not appear until the spring, though the flowers are out in September and October. The Autumnal Squill is a rather larger plant than the better-known spring variety, and its flowers are not quite such a beautiful blue, but, none the less, it is a valuable plant for the autumn garden.

For the actual winter, one should have the two Hellebores, *Helleborus viridis* and *H. fœtidus*. The former has flowers of a bright, clear green, while those of the latter are rather darker and of a purple hue. They are closely allied to the Christmas Rose, and if planted in a sheltered position will bloom in the very depth of winter. It is as well to cultivate berried plants for the winter, such as the Stinking Iris and Wild Arum, both of which have large heads of bright scarlet berries in the winter. All of these are plants suitable for an average garden without any special features, but, of course, if one has a rock garden or a pond, one can specialise still further. For the rock garden one can make a collection of British Saxifrages; there are about fifteen of them, and it would be a very interesting task gathering them all together. There are *Saxifraga oppositifolia* (purple), *S. aizoides* (bright yellow), *S. hypnoides* (white) and various others, including our old friend, London Pride. The Sedums would make another collection, and here again one finds a great variety, from the common yellow Stonecrop, that grows on walls and cottage roofs, to the big purple Orpine (*Sedum Telephium*), which sometimes reaches a height of 2 feet. Pinks, of which there are four different kinds, also the Gentians, will adapt themselves to a rock garden quite happily.

A pond has great possibilities for wild gardening. To take one of the largest and handsomest plants first, we must be sure to include the Flowering Rush (*Butomus umbellatus*). It has long, sword-like leaves 3 feet or 4 feet long, and in the summer splendid heads of rose-coloured flowers. One should, of course, have Water Lilies, both yellow and white, also the yellow Iris for the early summer, with Arrow-head and Water Plantain to follow. If the edges of the pond are damp and marshy, then there are innumerable possibilities of growing things like Bog Asphodel (*Hottonia palustris*) or Water Violet, Butterwort, Buckbean, &c. Even if the edges are not marshy one can make a great show with Loosestrife, Forget-me-not, Amphibious Persicaria, Skull-cap and various other plants. In fact, as soon as one turns to wild gardening, a vast range of new and interesting possibilities is opened up to us.

One word of warning in conclusion. Unless the plants are common, or you know that there are plenty of them to be had, do not go and dig them up yourself, but get them from a florist. Almost all the rarer British wild flowers can be obtained quite easily and cheaply, either plants or seeds, from a good nurseryman, and, there is no excuse for despoiling the country of rare plants. D. C.

THE GARDEN.

No. 2223.—VOL. LXXVIII.

JUNE 27, 1914.

NOTES OF THE WEEK.

The Great Spearwort.—What a noble waterside flower the native *Ranunculus Lingua* is, yet so very rare in English gardens. Its tall, straight stems, bearing very large, rich yellow flowers like giant field Buttercups, are very handsome. With this and similar moisture-loving plants more freely used we might obtain a fringe of beauty, not only of flowers, but also of foliage, to our pools and streams during the summer and autumn months.

The Shrubby Flax.—*Linum arboreum* is one among many others of a beautiful and useful class of plants. It is of a sub-shrubby character and well suited for the rock garden, usually attaining a height of 1 foot and as much through, although occasionally one comes across specimens twice that size. At the present time it is crowned with its golden cup-shaped blossoms. It is not in any way fastidious, but the best position for it is a sunny, well-drained one in gritty loam; and, should the soil be of a non-calcareous nature, it will greatly benefit by the addition of some old mortar rubbish worked in. The plant is easily raised from cuttings of the growth that follows after blooming.

The Speaker and Horticulture.—We have much pleasure in publishing a portrait of the Right Hon. James W. Lowther, P.C., LL.D., D.C.L., M.P., Speaker of the House of Commons, who is presiding at the annual Festival Dinner of the Gardeners' Royal Benevolent Institution on Friday of this week. This Institution is doing a vast amount of good work in granting pensions to aged or infirm gardeners, or the widows of gardeners. We hope that all of our readers will do what they can to support it. The secretary is Mr. G. J. Ingram, 92, Victoria Street, Westminster. In spite of his busy life the Speaker manages to find time to take a keen interest in practically all branches of horticulture, and may often be seen admiring the flowers at the Royal Horticultural Society's fortnightly shows. We hope at a later date to publish an illustrated description of the gardens surrounding his charming country residence, Campsea Ashe, Suffolk.

Rock Gardens at York Gala.—Rock gardens naturally form one of the great features of this exhibition, and the grand old stone of the Yorkshire moors is here used to great advantage. It is remarkable, however, that there is no special class for rock gardens at York. Class 2, which, according to schedule, is for a group of hardy plants and flowers, with a pool of water arranged for effect on the ground-

level, always brings a number of rock garden exhibitors into competition, although there is no mention of either rocks or alpine plants in the schedule. Surely it is time that the society altered its schedule to include a special class for rock gardens, and it is doubtful if any place in the British Isles is better situated than York for a really first-rate competition in this interesting phase of gardening.

THE RIGHT HON. JAMES W. LOWTHER, P.C., M.P., SPEAKER OF THE HOUSE OF COMMONS, WHO IS PRESIDING AT THE FESTIVAL DINNER OF THE GARDENERS' ROYAL BENEVOLENT INSTITUTION THIS WEEK.

The Misuse of Colour Terms.—There seems to be a growing tendency for raisers of new plants to include in their names some colour term that one might reasonably expect describes the colour of the flower. In two Roses of comparatively recent introduction the word "gold" appears, and purchasers naturally assume that they are buying Roses of golden yellow colour. But they have to get up early in the morning to see it,

because when the flowers have been kissed by the sun, the gold, elusive as the real thing, has departed. Then last week a good new Pæony with the prefix "golden" received an award of merit from the Royal Horticultural Society, yet its predominant colour is a charming shade of rose pink, what little yellow is present being almost hidden deep down among the numerous petals. This loose use of terms is misleading, and is certain to do raisers of new plants harm in the long run.

The Chelsea Flower Show for 1915.

On another page we publish a communication from the Rev. W. Wilks relating to the Royal Horticultural Society's Chelsea Show for next year. It will be seen that exhibitors have been asked to state whether they are in favour of the show being extended over more than the usual three days, or whether they would like the show to be opened on Wednesday instead of Tuesday. Considering the voting, the Council have decided to hold the show on three days only, and that these days shall be Tuesday, Wednesday and Thursday, as in the past. We think the Council have taken a wise step in coming to this decision. A flower show, especially where cut blooms are extensively used, is not particularly attractive after three days of warm weather, and we cannot think, considering all the circumstances, that more convenient days than Tuesday, Wednesday and Thursday could be chosen.

Fabiana imbricata.—This is one of the most interesting of plants, and, although it belongs to the same family as the Potato, so closely resembles a Heath from its outward appearance that, by the casual observer, it would at once be taken for a representative of that genus. It is a fairly quick-growing shrub, with upright habit, crowded with small leaves, the flowers being pure white and tubular in shape, and borne in great profusion. Like many other plants from the regions of Chili, it is only moderately hardy in some parts of this country, although in some favourable

districts it will make a handsome shrub, while in others it will often form an ornamental feature if given the protection of a wall. It is said to be a useful plant for growing in maritime districts where the climate is favourable, as few plants can stand the sea spray better than this. It is easily increased by cuttings, and, being a fast-growing plant, young ones soon replace an old plant, should any winter prove too hard for it.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Coronilla glauca Outdoors.—The specimen shown in the accompanying illustration is planted on the south front of Theberton Hall, on the East Coast and not far from the sea. It has been flowering ever since last November. It is well worth a place in the garden for winter flowering. The plant is 6½ feet high and 6 feet wide.—W. H. COLLETT, *The Gardens, Theberton Hall, Leiston, Suffolk.*

Mazus reptans.—This handsome little plant has been grown in this country now for some years under the name of *Lobelia radicans*, and it was not until last year, when it was shown by the Wargrave Hardy Plant Farm at a meeting of the Royal Horticultural Society and given an award under the name of *Mazus rugosus* (which, by the way, is a weedy annual by comparison), that any interest was shown in it. It is a free-growing, pleasing little plant, blooming continuously from spring to late autumn, although perhaps not so freely as some plants. It prefers a cool spot in a sheltered nook, when its prostrate stems will creep about freely and the small green leaves form quite a dense carpet, above which are borne the purplish flowers, with yellowish white throats and reddish orange dots. In general appearance they very much resemble some of the small *Lobelias*. It is easily increased, as the young creeping growths root as they go, or they may be taken and placed under a handlight.—F. G. PRESTON, *Botanic Garden, Cambridge.*

Fecundity of Plants.—Having to hoe a border of the wild garden recently, I was struck by the remarkable fecundity of certain plants and the facility with which their seeds germinate, even under the most unpromising conditions. The Foxgloves, the Forget-me-nots and the Iceland Poppies are the examples I have in mind, where in each case young plants come up year after year in such remarkable numbers as to give the impression that the plants are perennials of most spreading habit. The seeds of many plants are exceedingly numerous. For example, the Henbane is calculated to produce from 30,000 to 50,000 seeds. The Poppy is almost equally prolific, and hundreds of others in this country or in their native home seed with such freedom as to make one wonder what would happen if every seed germinated. Here is an interesting theoretical calculation: One grain of Oats sown in an ordinary field will grow and branch, many of the branches producing a head of grain. For the calculation let us take modest estimates, say, eight branches each bearing thirty grains, so that the resulting crop is 8×30 times the amount sown. To argue that the crop should mean a return of 240 times the amount sown is pure nonsense; but where is the enormous loss, and cannot science do something to reduce that loss just as it is at present trying to attain satisfactory intensive cultivation?—H. H. A.

Roses on Their Own Roots.—It is quite a debatable point whether or not it is worth the time and trouble spent in striking cuttings of Roses to

raise a stock of plants to grow on their own roots. Years ago I struck many cuttings of Hybrid Perpetual varieties under glass and in the open. Some were a success, such as *Magna Charta* especially. Plants of this variety are still flourishing. La France, too, succeeded very well for a brief period, and so did Paul Neyron and John Hopper, as well as *Marquise de Castellane*. Many of the dark-coloured sorts like *Duke of Edinburgh* were too weak in growth to succeed; they seemed to require the aid of a wild Briar to make them grow well. I have tried of late many cuttings of climbing varieties, and find they succeed much better; but even these are not to be depended upon always. Many other sorts might be cited in support of my doubtful views as to the desirability of depending upon plants from cuttings. I think perhaps, if the plants so raised were tested in rows for one or two seasons before finally placing them in their permanent quarters, some disappoint-

A GOOD SPECIMEN OF CORONILLA GLAUCA GROWING OUTDOORS AT THEBERTON HALL, SUFFOLK.

ment might be saved. I recently saw in a nursery fifty plants of the variety *American Pillar* that had been so tested, and certainly the result well justified the trial. Such strong-growing sorts as *Félicité Perpétue* I know will flourish on their own roots equally well with the budded plants, but this variety perhaps stands alone in its vigour.—E. M.

Rehmannias for the Open Border.—*Rehmannia angulata*, and especially the variety *Pink Beauty*, is deservedly popular as a conservatory plant; but, excepting my own experience with it, I have only once come across it in the open border. That was at Hopetoun House, Linlithgowshire, when those gardens were under the charge of Mr. Thomas Hay, now Superintendent of Greenwich Park. So successful was Mr. Hay's experiment with it that I determined to follow his example, and the results have been equally satisfactory. Seed should be sown about midsummer in a pan in a greenhouse temperature, and when the seedlings are fit to handle they should be pricked out into

other pans or well-drained boxes, and in course of time potted up into 3¼-inch pots. If well attended to as regards watering, they may remain in these pots till planting-out-time, although it will be a great advantage if they can have a shift into 5-inch pots in the spring. The plants should be twice pinched to induce a bushy habit. Cool conditions suit them best, and they should be gradually hardened off so that they may be planted out in May. A few clumps of three in a herbaceous border help to give it a look of distinction. I am not quite sure where this species hails from, but botanists tell us that the genus is confined to China and Japan, and the other two introduced species, *A. chinensis* (syn. *glutinosa*) and *A. rupestris*, hail from North and Western China respectively.—CHARLES COMFORT.

Lifting Tulips.—In a letter to the Editor "H. B." asks my advice about lifting Tulips in a garden where the soil is heavy, and also in one where it is light. I think there is no doubt whatever that Tulips do better when they are lifted and replanted every year, whatever the soil is. As the bulb loses the whole of its roots, or, to speak more correctly, as the new bulb makes no roots for a considerable time after the roots of the old one have perished, nothing is gained by their being left undisturbed, except perhaps an earlier start into life, which is just the one thing most of us do not want to facilitate. The foliage comes through the ground quite soon enough in our trying climate when the bulbs are planted in November. "H. B." also enquires about the treatment of Tulips when they are lifted. As soon as the stems and leaves have gone quite withered-looking and dry, take up the bulbs, cut the dead foliage off, and spread out thinly in boxes or on a floor out of the reach of the sun and draughts, but with plenty of air. When they have become dry, clean the bulbs and store them in a dry place in paper bags until planting-time. The smaller bulbils should be put by themselves in a nursery bed to grow on, and be planted in September. The very small ones had better be thrown away, except those of any very special sort.—JOSEPH JACOB.

An Iris Contrast.—It is somewhat remarkable that the beautiful Chinese Iris *Delavayi* is not more generally grown in gardens. This, however, may be due to the fact that its beauty has yet to be seen by many garden-lovers. There is nothing quite so rich in the violet hue among Irises as *Delavayi*, unless it is one or two of the finest of the *Kämpferi* Irises. In any case *Delavayi* is a plant to grow. It is a true moisture-lover, tall and graceful, and with just a touch of white on the petals to relieve the intensity of the violet. We use *Delavayi* for bedding with speciosum Lilies, and as such it is quite a success. Its finest effect, however, is against a mass of *I. aurea* or *I. Monnieri*, where the intense hue of *I. Delavayi* is admirably heightened and contrasted by the golden colouring of *I. aurea*, *I. Monnieri* or any similar Iris. All these Irises are of fairly easy growth, and do best in a loamy soil enriched with farmyard manure, and neither should be omitted from any representative collection.—P. S. HAYWARD.

A Use for Bishop's Weed.—Mr. Brotherston is to be much congratulated on having found one use for this, as mentioned on page 303, issue June 13. I never thought it had any use. I always like to know and have asked many people why it was so called. No one could tell me; but one gentleman, after pondering the matter for a while, said, "It might be the difficulty of getting rid of it."—T. SMITH.

Primula Leddy Pilrig.—I am much obliged to Mr. Robertson (page 302, June 13) for his information regarding the parentage of his hybrid Primula Leddy Pilrig. The note will be exceedingly useful to hybridisers of these valued and valuable flowers, and it is quite evident that Mr. Robertson is absolutely correct in his knowledge of the parentage of his Primula. The opinion I expressed was that of several authorities of experience in hybridising and raising seedlings of these Chinese Primulas, but that goes for nothing in view of the courteous statement of Mr. Robertson. P. Leddy Pilrig is quite a pleasing plant, which many who saw it would doubtless be glad to possess.—S. ARNOTT.

Too-much-alike Auriculas.—Your correspondent is quite right regarding the carelessness of exhibitors who in some instances acquire new varieties and without consulting the raiser exhibit and rename them. He refers to the alpine variety Unexpected, and rightly says, or infers, that Exquisite is the same. It is a fact that it was exhibited first as Unexpected; but that old enthusiast, Mr. Joseph Stokes of Harborne, was the raiser of it, and he it was who sent it out as Exquisite. I believe it was the result of crossing two good varieties, Dean Hole and Enteric (the latter, although anything but a cheering name, was a lovely bloom), one of the many good ones introduced many years ago by that veteran Auricula specialist, the late Mr. Pohlmann of Halifax, who died before growers had learned to appreciate his beautiful achievements among alpine varieties, although both gentlemen made their mark in the stage varieties also.—W. P.

Hardy Primulas in Scotland.—Knowing that Mrs. de Pree of Saughton House, Corstorphine, Midlothian, was specialising in Primulas, I visited her garden towards the end of May expecting a treat; nor was I disappointed. This garden is a veritable *multum in parvo*, where rosary, wall garden, moraine, rockwork and herbaceous borders are all included and all well done; but it is of the Primulas I wish to write, and especially of P. pulverulenta, P. Veitchii and P. cockburniana. These are all grown by the score in colonies and in different situations, some in partial shade and some in full sunshine, but all in the pink of health and blooming most profusely. I found that in the case of P. Veitchii the depth of colour varies considerably, and by means of selection Mrs. de Pree and her gardener, Mr. Hunt, hope to raise an improved strain of this beautiful Primula. With regard to P. pulverulenta, it proves more vigorous in full sunshine than in partial shade, but the flowers suffer somewhat from the sun's rays. The flower-stems of this fine Primula averaged 22 inches in length. P. Forrestii, which is being appraised at a high value, I was not much enamoured of. Here at least it thrives best in a shady part of the wall garden. P. Sieboldii in variety and P. cashmeriana are also grown in quantity here, and others grown are P. beesiana, P. capitata, P. marginata, P. frondosa, P. rosea, P. sibirica, P. Kellereri, P. involucrata, P. hirsuta, P. The General, P. Julæ, P. Auricula

Double Red and P. A. Double Yellow.—CHARLES COMFORT.

Lopezia miniata.—Though this distinct and pretty flowering shrub is better known in the West of England than in other parts, it is well worth attention as an ornamental subject for the greenhouse, where with attention it will flower during the spring and well on into the summer months. It is a near relative of the Fuchsia, but in general appearance differs markedly therefrom. This Lopezia forms a freely branched little shrub, clothed with ovate leaves about an inch long and plentifully furnished with hairs. The flowers, which are produced from the axils of the leaves on the upper parts of the shoots, are bright rosy red in colour and of a very peculiar shape. When fully expanded they are not more than half an inch across, but are borne in great profusion. A singular feature of the flower is the two-stalked petals, which stand out on either side in a strange wing-like fashion. This Lopezia is a native of Mexico, and may be given much the same treatment as a Fuchsia, except that, the wood being thinner, the plant should not be subjected to a pronounced drought during the winter, while at that season the temperature should not fall below 40°. The leaves are very liable to be attacked by red spider, so that the plants should be freely syringed during the summer.—H. P.

Aids to Vegetable Growth.—During the month of June there are no more important details in vegetable culture than those of watering, mulching and syringing of the various crops, yet among amateurs these points are so little understood, and therefore their value is not appreciated to the extent they should be. So many persons say, "If I begin to water my crops, I must continue; therefore I had better not commence." This is a great mistake; one good soaking may save many crops if proper steps are taken to conserve the moisture in the soil afterwards. What is known as the dribbling system of watering is certainly not to be recommended, as this does more harm than good, because it encourages the roots near the surface, and if moisture is not maintained, the plants suffer in consequence. Give sufficient water to thoroughly wet all the roots, and the plants will show their appreciation by stimulated growth. After watering, conserve the moisture in the soil by applying a mulch of manure of a half-decayed nature, some 3 inches thick. If manure is not available, decayed vegetable refuse, lawn mowings or old potting soil will suffice. Failing even this, the next best thing is to keep the soil stirred near the plants by the aid of the Dutch hoe or small fork. Syringing such plants as Peas, Beans and Turnips in the evening after a hot day does much good, keeping the foliage cool during the night and aiding growth considerably, and very often preventing an attack of thrip to Peas or red spider to Turnips.—E. MOLYNEUX.

FORTHCOMING EVENTS.

June 30.—Royal Horticultural Society's Summer Show, Holland House, Kensington (three days)

July 1.—Flower Shows at Colchester, Reigate and Southampton.

July 2.—Norwich Summer Show. Streatham Rose Show.

July 3.—Dundee Horticultural Association Meeting.

July 4.—Société Française d'Horticulture de Londres Meeting. Sutton (Surrey) Rose Show. Northwood Rose Show.

ROSE SPECIES AS GARDEN PLANTS.

THE employment of Rose species in our gardens has undoubtedly increased of late years, but is well worth further consideration on the part of those who have room for them. No doubt to those who regard their beds and borders merely as nurseries for the production of flowers to be staged at exhibitions they will make but little appeal, for their beauty is at its height through May and early June, and their flowers are, for the most part, over long before the time for Rose shows arrives. For a similar reason, those who see little of their gardens till July or August will, perhaps, not set much store by them. Again, their period of flowering is generally very short, not often exceeding a fortnight of full flowering in any individual case. Moreover, as cut flowers they cannot compete in usefulness with many of the modern decorative varieties of Roses, except, perhaps, on the very few occasions when a plant can be caught at its very best. But let us recognise their limitations and treat them rather as flowering shrubs, and not in any way as substitutes for garden Roses, and we shall find many of them of great interest.

In relation to the Rose garden proper, their position should be rather on the outskirts than within the precincts. Here some may be trained into beautiful little hedges of varying heights, according to the species employed; or, where space is available, a large bed or border may be formed for a collection, or smaller beds of one or two or three kinds; while there are some which will form fine isolated specimens on lawns or in grass, and in such positions are beautiful all the summer for their foliage. There are many of the species that can be used with effect in the rockery or in its neighbourhood; but it is not of these that I am particularly thinking to-day. These Rose species are also suitable for forming little groups in the front of an open shrubbery border containing other flowering shrubs; but I do not think they mix well with ordinary herbaceous subjects, except, perhaps, with Lilies and hardy Fuchsias.

Perhaps I ought to state that I am using the expression "Rose species" (for want of a better) in a somewhat inaccurate sense, without any botanical significance, to include not only botanical species, but many forms and varieties of similar habit. Many of those I shall name are undoubtedly hybrids, and some, perhaps, of garden origin; and though it may be that most of them have, at some time or another, been described as species, it is a rank to which they certainly could not all be admitted nowadays.

I will begin with the great Scotch Rose group and its allies, which include some of the earliest and most beautiful. R. pimpinellifolia itself, though very charming and, if planted on poor soil, producing its delightful single creamy white flowers only a few inches above the ground, is too small for our purpose; but the pink and blush double Scotch Roses make a first-rate low hedge, and the form Lindley called grandiflora, now known as

Rosa altaica, is alike one of the hardiest and most beautiful. It forms a compact little bush about four feet high, producing large white flowers, occasionally attaining a size of 5 inches across. When procured upon its own roots and doing well, it forms numerous root shoots or suckers from the

base, and this and its habit of growth make it particularly suitable for forming a low hedge 3 feet to 4 feet high. When used in this way, it is sufficient to tie the growths, some time during the winter, slantwise to one another, and the hedge soon forms. An occasional flower is produced in autumn as a pleasant surprise. The berries are a deep purplish black and not very conspicuous. *R. altaica* also looks well in a little group of six to twelve plants, or may be associated with *R. hispida* and *R. xanthina*, which have a somewhat similar habit of growth.

R. Alberti has flowers of a good clear yellow colour, which are very pleasing. It is rather more arching and spreading than the last Rose, and decidedly more tender, requiring, as it seems to me, richer soil and more careful cultivation.

R. hispida has a very charming flower of clear primrose yellow, nearly, if not quite, as large as *R. altaica*. The habit of the plant is of similar

flowers are of a paler yellow colour. It seems hardy enough, and makes a good bush.

R. rubella is a pretty little plant, and one very common in botanic gardens. It has soft pink flowers and small but pretty leaflets, and possesses the peculiarity among members of this group of having red berries. It is of hybrid origin.

R. spinosissima lutea is a Rose growing slightly taller than *R. altaica*, but of much the same habit, except that it is not quite so well furnished with foliage to the base of the plant. It has, however, the finest coloured yellow flowers of the group, as deep as Persian Yellow, which always attract attention. Professor Crépín thought this a hybrid.

R. xanthina, the last of this group I shall mention, is, perhaps, one of the most satisfactory, and there are few things more effective during the short time they are in perfection than a group of plants of this Rose in full flower. The flowers are

A big-growing hybrid of this species, *R. stenosepala*, is interesting for the quantities of red berries it produces in autumn.

R. macrophylla, from the gardener's point of view, may be regarded as an alpina with the characters exaggerated. The long leaves, with the large, loose leaflets of alpina, are here longer and larger and more highly coloured, especially in autumn, while the urn-shaped berries are longer and more fantastical. Its foliage and fruit are its chief merits as a garden plant; but the very long, twisted sepals are curious, and give a character to the large single pink flowers. To be seen at its best, the plant requires more careful treatment than *R. alpina*. There is, however, a variety, *R. oxyodon hæmatodes*, which I imagine to be a hybrid of this Rose, that is of easier culture. In connection with this group I should mention

R. Moyesii, a very beautiful and interesting plant growing to a height of 8 feet or so. The flowers are a wonderful terra-cotta pink and very beautiful, and the foliage is of a beautiful glaucous hue. It seems quite easy to grow, but by no means so easy to get to flower profusely. I have recently moved my plant, which had attained considerable proportions, to the foot of a south wall under the protection of a Cherry tree, and it is only just recovering from the disturbance. Though I incline to think sun and some slight protection are the conditions it requires, I do not yet feel in a position to write confidently about it. A quaint little plant,

R. microphylla, of low stature and with beautiful Fern-like foliage, is one of the curiosities among Roses. It bears berries resembling those of the Spanish Chestnut.

R. sericea is one of the finest of Rose species, and best as an isolated bush, when it will attain a considerable size—8 feet or 9 feet high, and even more in diameter through the bush. There are probably several forms which have not yet been distinguished by names. Some have red berries, and others, which I prefer, orange berries. The flowers are white, with four petals, and produced in early May,

and the foliage is most graceful and Fern-like. Long, straight shoots are produced from the base and centre of the plant, the older ones gradually arching downwards to clothe the base. Leave it alone when doing well.

R. sericea pteracantha, remarkable for its enormous thorns, red and translucent on the young wood, requires very different treatment. Here the maximum production of young wood is wanted, so it should be cut down immediately after flowering. Two other Roses I must refer to. One,

R. rubrifolia, is becoming well known for its lovely foliage. Bear in mind that it is a plant of the high alpine valleys. The other is

R. Andersoni, a hybrid of the *systylæ* group, but approaching the habit of *canina*. This Rose is remarkable for the abundance, brilliancy and beauty of its pink flowers, which will often vie with the garden Roses themselves.

H. R. DARLINGTON.

THE FORMAL SUNK GARDEN AT BLECHLEY PARK.

rather upright, yet fairly bushy growth, and the foliage characteristic of the Scotch Rose family; but it possesses the peculiarity of having very numerous setæ, or fine needle-like prickles, but no thorns.

R. Hugonis is the earliest of this group, but alas! one of the most tender. I have had a bush of it 4 feet and 5 feet high, with its arching stems covered all their length with its beautiful yellow blossoms about the size of half-a-crown. But never has it lasted like this for long. Time and again a spring frost, coming just as the flower-buds were bursting, has killed all the upper branches, leaving only the lower and more protected ones to carry on the life of the plant and help it to throw up its pretty young basal shoots and re-form the plant for another year.

R. ochroleuca is another yellow-flowering Rose, probably of hybrid origin, bearing some resemblance to *R. xanthina* in its stems and prickles, but the

of a fine yellow colour, not so clear and deep as *spinosissima lutea*, but more freely produced and somewhat larger. *R. xanthina*, though a near connection of the Scotch Rose family, has the peculiarity of possessing sharp, well-developed thorns, but no setæ. It is of quite easy culture and hardy. On the other hand, the dwarfier *R. Ecæ*, from Afghanistan, which is possibly a form of the same Rose altered by habitat, is very difficult to get to flower in this country. Of

R. alpina, the Thornless Rose, one of the parents of the Boursaults, there are three forms at least worth growing as flowering shrubs for the spring garden. *R. alpina* itself looks very well when the blood red flowers first open, and is curious afterwards for its urn-shaped berries. It is best as an isolated plant, growing 4 feet to 5 feet high. *R. alpina pendulina* has even more beautiful foliage and more graceful habit, while the variety *pyrenaica* has a few prickles and is much dwarfier,

ROSE-GROWING IN TOWN GARDENS.

THERE has been something of an outburst recently against scentless Roses, and there are those who tell us that to lose the scent is to destroy the soul of our national flower. Let such folks revel in their Hybrid Perpetuals! A sweet-smelling Rose is a joy to everyone, and I have no wish to belittle the importance of scent, but I regard it as of much less merit than shapeliness. Surely there is greater reason for pleasure in the perception of beautiful and artistic symmetry of form than in the mere tickling of the olfactory nerves, and certainly a "feast for the eyes" appeals more to the poetic sense than a "feast for the nose." The one is an intellectual pleasure, the other merely a sensual enjoyment.

There can be no single standard of shape; there are so many, each equally beautiful when brought to perfection. For there lies the secret. Almost every Rose will produce a shapely bloom if there is sufficient vigour in the growth to enable it to do so. To the unsympathetic a Rose bloom is just good or bad; to the lover of the flower it is a source of joy or otherwise, as it has been well or badly used.

This is borne in upon us particularly at the present moment, when our early blooms are suffering to some extent from checks which have delayed them too long in the bud. In many cases frost has crippled the foliage as well, and the early summer has proved anything but an ideal one so far. But the English summer that proved entirely suitable for Roses has yet to come, and one must be prepared to lose the results of a number of the early growths.

It is extremely difficult to guard against spring frosts, and the mischief they do among the more tender plants is soon apparent. The only precaution one can take is to see that the foliage is kept as dry as possible when there is any likelihood of a cold night, and spraying the plants at such a time should be carefully avoided. A check in the early stages of development is a misfortune from which numbers of the buds are unable to recover, for there is little doubt that the split centres from which many of the flowers suffer are due to this cause. The tendency is, of course, inherent in some Roses, and one would not expect a J. B. Clark without a division somewhere. Others that are chiefly affected are those with many rows of petals, and are usually vigorous kinds. It would seem as if the delay in development was confined to the sepals, while the petals, in endeavouring to expand without increased room, were forced out of their natural position.

P. L. GODDARD.

GARDENS OF TO-DAY. BLETCHLEY PARK, BUCKINGHAMSHIRE.

OUR first acquaintance with Bletchley Park, the Buckinghamshire seat of Sir Herbert and Lady Leon, was made a few years ago when visiting the flower show held annually in those delightful and extensive grounds. The parkland is beautifully situated and well wooded, while magnificent views may be obtained of the surrounding country through open vistas and avenues in the higher parts of the estate. Our last visit was made a few weeks ago, when Lilacs and Laburnums,

PHLOX NEWRY SEEDLING IN THE FOREGROUND AND DOUBLE ARABIS AMONG THE UPPER ROCKS IN SIR HERBERT LEON'S GARDEN.

against a background of dark green conifers, converted the carriage drives and garden walks into avenues of unusual splendour with purple, white, and golden-coloured flowers. The mauve-tinted Persian Lilac and the white Charles X. were most effective. The gorgeous effect produced by planting Lilacs and Laburnums in this way leads one to enquire the reason why these common but beautiful trees are so often relegated to obscure corners of the garden and pleasure grounds, instead of being given—as at Bletchley Park—the prominence they most certainly deserve. Trees and shrubs, not unnaturally, form one of the charms of these gardens in leafy Buck., and glorious effects have been created with foliage trees, in which Copper Beeches, Golden Maples

and *Prunus Pissardii* play an important part. A promising young tree of *Sophora japonica* occupies a prominent place on a spacious lawn near the south front of the house. The tree, raised from a seed brought by Lady Leon from Washington in March, 1897, is now of spreading habit and about twenty feet in height, but so far it has not flowered. Shrubby *Spiræas* are much in evidence; *S. prunifolia*, *S. van Houttei* and *S. Douglasii* being used with good effect.

Rock and Water Garden.—An extensive rock garden has been made to take the place of a steep bank at the head of a lake. Although of recent construction, the rock garden is already splendidly furnished with large patches of alpine flowers. These are effectively planted, and the bright masses of mountain flowers are reflected in the placid waters beneath. Saxifrages and *Androsaces* both do well on this rocky bank. *Saxifraga* Red Admiral flowers with great freedom, and even the rarer *S. Faldonside* and *S. burseriana* give quite a good account of themselves. *Violas*, *Ericas* and *Lithospermums* are other subjects that look particularly happy in their congenial surroundings.

A small Water Lily pool in an enclosed garden, surrounded by a paved walk and a wealth of alpine flowers suitably planted among rocks, makes a most pleasing feature. The illustration of the stone steps leading to the pool gives an idea of the quiet beauty of this secluded garden. The design is simple, happily conceived, and carried out in good taste. Between the paving-stones low-growing plants like the Thyme, Thrift, wall Campanula and Kenilworth Ivy spread naturally, while the rocky banks are clothed with alpine *Violas*, *Saxifraga decipiens*, *Heucheras*, *Alyssum*, double *Arabis*, *Aubrietia* Dr. Mules, *Phlox subulata*, *Corydalis lutea* and *Arenaria balearica* (the Creeping Sandwort). Another rock garden links up the lawn with the shrubbery. In this case rambling Roses over rustic poles, together with a great variety of ornamental foliage and flowering trees, make a fitting background to the rock garden. *Cotoneasters* and Rock Roses are planted here to advantage, while *Phlox Newry* Seedling, double

Arabis, followed by *Campanulas* and *Dianthus*es in variety, grow freely and flower in profusion over huge rocky boulders.

Bedding designs are carried out on an extensive scale, and the illustration on page 328 shows a sunk garden of formal outline, in which the beds are filled with Wallflower Cloth of Gold, *Myosotis alpestris* and white *Violas*. Of Tulips for spring bedding, the varieties *La Merveille*, *Clara Butt*, *Glow*, *Bouton d'Or* and *Farncombe Sanders* are the most favoured.

In addition to the beautiful pleasure grounds and flower garden, the kitchen garden, fruit-houses and plant-houses all reflect the highest credit upon Mr. G. Cooper, the genial and able head-gardener.

REGAL PELARGONIUMS.

THE term "Regal" is applied to a section of large-flowered Pelargoniums nearly related to the show and decorative classes. As Nature draws no hard-and-fast line, these groups merge into one another by almost imperceptible gradations, so that it is in some cases impossible to say to which section they belong.

In the first half of the seventies of the last century, the first of the Regal Pelargoniums made its appearance in the variety Queen Victoria. This, with its thick, crisped petals, which presented the appearance of a semi-double flower, in colour vermillion, margined with white, was quite a break away from any then known, and there was a very large demand for it—so large, indeed, that great numbers were sold at a guinea a plant. Other varieties, such as Beauty of Oxton, Captain Raikes and Dr. Masters, soon made their appearance, till the list of Regal Pelargoniums became quite a long one. Owing, however, to the popularity of this section, others that would be more properly classed as decorative were often included therewith. A few of the best of the Regal varieties would include Beauty of Oxton, Beatrice Hume, Captain Raikes, Dr. Masters, Emmanuel Liais, Lady Duff, Duke of Fife, Bush Hill Beauty, Princess Teck, Champion, Miss Lily Cannell, Volonté Nationale, Gloire de Tours, Prince Teck and Prince of Wales.

Cultural Requirements.—This class of Pelargoniums need the same treatment as the nearly allied kinds; that is to say, they are readily increased by cuttings, and are grown on in good loamy soil in a light and airy greenhouse. By varying the treatment as to temperature and potting, they may be had in bloom from May till the end of the summer. The best time to take the cuttings is directly the flowering period is past, the plants being cut down to within a few inches of the soil. Prior to cutting them down, the roots should be kept rather dry for a few days. From these cut-off portions of the plants the most suitable cuttings should be chosen, selecting for the purpose the short, sturdy shoots that are likely to develop into good bushy plants. All weak shoots with a tendency to flower must be avoided. About three inches or a little more is a suitable length for the cuttings, which must be inserted into clean, well-drained pots of sandy soil. The compost may be made up of loam lightened by a little leaf-mould and sand, the whole being passed through a sieve with a one-third of an inch mesh. As much of the soil as possible should be rubbed through. When the pots are filled, they should be duly labelled and watered through a fine rose, after which they may be stood on a light, airy shelf in the greenhouse or in a similar position. If inserted in July, the cuttings will be well rooted

within a month, when they will be fit for potting off. For this purpose 3-inch pots are very suitable, and the same kind of compost as before recommended for the cuttings may be used, but it should not be sifted. In a good, light position in the greenhouse the young plants will grow away freely, so that the most forward may be shifted into 5-inch pots by the autumn. They must, when young, have the growing points pinched out, in order to ensure a bushy habit of growth. Some varieties will require more frequent pinching than others. As the plants go out of flower, cuttings may be put in up to the end of August or even later; but, of course, these will take

the best way of keeping the plants free of this pest.

Old Plants.—When the old flowering plants are cut down as before mentioned, they should be stood on a stage in the greenhouse fully exposed to the sun. They will not require any water at the roots, but should be bedewed over two or three times a day with the syringe. Under this treatment young shoots will soon be pushed out, and as soon as the most forward are about half an inch in length, the plants should be repotted. They must be shaken quite clear of the old soil, when, at least in some cases, it will probably be found that there are but three or four roots coiled around the pot. These roots should be cut back hard, and all the plants be repotted into a much smaller pot than they were in before. Some will by autumn need repotting, but the bulk may be left till the spring. At all events, these old plants may, if desired, be grown into much larger specimens than those obtained the first year from cuttings. H. P.

ROCK GARDEN BY THE LAKESIDE AT BLETCHLEY PARK.

longer to root than the earlier ones, and consequently they are best wintered in small pots. In early spring they may be put into those in which they are to flower, 5-inch and 6-inch being very suitable, using turfy loam with a little leaf-mould or well-decayed manure and sand, and taking care that the soil is pressed down firmly. This last item is a very important one in the culture of these Pelargoniums, as, if potted loosely, the shoots run up quickly and become bare at the base before the flowering period. When the pots are well furnished with roots, stimulants must be given; but it should be borne in mind that cuttings from highly fed plants do not root so readily as those to which little stimulant has been given. In all stages of growth green fly gives a good deal of trouble, requiring being

that flower earlier. Turning to other bulbous plants, we find the early flowering Gladioli particularly useful in such varieties as Colvillei alba, The Bride (pure white) and cardinalis (scarlet, with white flakes). Blushing Bride is a pleasing combination of white and pink, while Peach Blossom and Rosy Gem are titles that need no comment. Following on these are the Spanish Irises, which for cutting can scarcely be equalled. Some pretty colours include Cananus (deep golden yellow), Reconnaissance (dark bronze with gold blotch), King of the Blues (a fine dark blue), British Queen (white, striped orange) and Louise (pale blue). The English Irises flower a few days later, and some good examples are Proserpine (dark purple), Mont Blanc (white, with yellow band down the centre) and Prince Imperial (clear blue).

HARDY FLOWERS FOR CUTTING.

THAT hardy flowers are more popular to-day than ever goes without saying, but those that are adapted for indoor decoration are, perhaps, the most useful. To be able to cut them with the freedom that one ought, it is advisable to have a reserve plot for the purpose, as cutting from the permanent borders is seldom satisfactory, for fear of spoiling the effect. Such a plot should be situated in a good growing position and be well cultivated, and planted more for ease in cutting rather than for effect.

The earliest flowers available are the Narcissi; but as these are usually planted under more natural conditions, they are not a necessity in this plot, unless it be the late Gardenia-flowered variety, *N. albus plenus odoratus*, which appears to delight in rather better attention than do those

After these come the beautiful white spikes of *Hyacinthus (Galtonia) candicans*; these are very useful for tall vases along with the late summer-flowering *Gladioli*. This section is larger and more stately than the early-flowered varieties, and they are seen at their best in such forms as *blechnensis* (brilliant scarlet) and the many charming hybrids.

Among the Lilies we have a wide choice, and as many of them are happier when not disturbed too frequently, the site for them should be thoroughly prepared previous to planting. In the speciosum group we have such sterling varieties as *s. Melpomene*, with rich crimson flowers, heavily spotted and edged white; *s. album*, pure white; and *s. rubrum*, white, with red spots. Other most useful forms include *L. candidum* or the Madonna Lily, also the beautiful Orange Lily (*L. croceum*), while *L. tigrinum* (Tiger Lily) and the charming *L. canadense* are indispensable. Of *Montbretias* it is impossible to speak too highly, as they are so light and graceful, and in colours that are very effective under artificial light. They have also been considerably improved of late years, a fact which is very noticeable in such varieties as *Prometheus*, with its tall branching spikes of rich orange flowers that are shaded and spotted with crimson in the centre. Others of equal merit are *George Davison* (pale orange), *Koh-i-noor* (deep yellow on apricot base) and *Germania* (orange scarlet). The foregoing notes, though not exhausting the suitable list of bulbous plants, serve to show that from June till well into October there is more or less of a succession, and the same is possible to a greater extent among plants at very little cost, as many of them can be raised from seed sown in early summer.

Commencing with this convenient section, one of the most useful is the *Aquilegia*, as few hardy flowers come in earlier and are more effective in vases of any description. These are followed by the *Pyrethrums*, which for their beauty and free-flowering nature are well worthy of extensive cultivation. From a packet of seed some good varieties are obtainable; but where this method of obtaining a collection is not adopted, the following is a selection of the best forms. Among the doubles are *Lord Rosebery* (scarlet), *Aphrodite* (white), *Duchess of Teck* (pink) and *Lady Kildare* (buff yellow). Some pleasing singles are *Ixon* (bright rose), *James Kelway* (crimson), *Ahmed* (pure white) and *Fairfax* (pink). For July flowering the brilliant colours of the *Gaillardia* and of *Coreopsis grandiflora* are indispensable.

In *Heuchera sanguinea* we have a typical herbaceous plant, and as its flowers are most useful for cutting, it should not be overlooked. *Delphiniums* are beautiful in their varying shades of colour. Among the named varieties they are seen to perfection. *Belladonna* is a lovely blue with white eye; *Euchantress*, light blue. In *Barlowii* the flowers are deep blue, shaded red, while for a pale yellow there is none to compare with *Beauty*

of Langport; it is a semi-double, and its well-formed spikes are freely produced. Another charming flower is *Scabiosa caucasica*. In colour it is pale lilac, and as the flowers are formed on exceptionally long stems, it cannot be too highly praised. A vase of Sweet Peas is incomplete without that charming little flower, *Gypsophila paniculata*.

The Giant Oriental Poppies are not favourites with everyone; but as they are practically alone where size and rich colouring are concerned, they are worthy of a little space. Of a more graceful appearance are the Iceland Poppies, and though, like others of the same family, they are short-lived, vases containing them more than repay for the trouble of everyday replenishing. *Lychnis chalcedonica* is also worthy of note for its brilliant heads of scarlet flowers. The Ox-eye Daisy (*Chrysanthemum maximum*) is useful, as are some of the Campanulas, notably *C. grandis*, *C. pyra-*

and fragrance nothing can equal *Hesperis alba flore pleno*. Other varieties are *H. lilacina* and *H. purpurea*. All of them are at their best towards the end of June.

The Phloxes are general favourites, especially in such an excellent variety as *Amabilis* (bright salmon with crimson centre). *Iris* is a beautiful shade of violet blue; *Amazon* is pure white; a beautiful rose pink is *Eclairer*; while for an excellent scarlet *John Stewart* is worthy of note. *Achillea Ptarmica* The Pearl is at its best in July, as are also *Helenium pumilum magnificum* and the newer variety *Riverton Gem*. With the approach of September there is a wide choice of suitable flowers. The outdoor *Chrysanthemums* are approaching their best, the perennial *Sunflowers* give us an abundance of yellow flowers, and the Japanese *Anemones* supply the always big demand for white flowers, while the brilliant spikes of *Kniphofia*

STONE STEPS LEADING TO THE WATER LILY POOL AT BLETCHLEY PARK.

midalis and *C. persicifolia*. All the above repay for good treatment to fit them for early spring planting. There are others not generally raised from seed that should on no account be overlooked, as they include some of the brightest and most reliable flowers for all purposes. Of these the earliest to flower are the *Doronicums*, two useful varieties being *D. austriacum* and *D. plantagineum excelsum*. Both bear yellow flowers on long, slender stems, but the last named is of a more robust habit, growing some two feet higher than the former. *Dielytra spectabilis* and *D. s. alba* bloom at a time when outdoor flowers are none too plentiful, and as their graceful racemes of pink and white are much sought after for tall vases, they are worthy of good treatment. *Anthemis tinctoria* (rich yellow) and *A. pallida* (creamy yellow) are both useful plants, as their period of flowering usually extends over a few weeks. *Inula glandulosa* is another yellow flowered plant not to be missed; but for purity

Uvaria are readily made room for. These are not over before the Michaelmas Daisies come in cloud-like clusters to last until the cold nights prove too much for them. Of these, *Beauty of Colwall*, *Climax* and *Amellus Perfect Beauty* are indispensable.

F. J. TOWNEND.

HERBACEOUS BORDERS.

In addition to staking and tying, the flowering stems of such plants as *Lupines*, *Doronicums* and many other early flowering subjects should be cut over as soon as they begin to fade. In the case of *Lupines* and *Delphiniums*, they usually throw up a second crop of flowers in the autumn, which are most acceptable. Should any vacant spaces appear in the border as the result of this cutting, these could be filled up with suitable annuals or other plants that may be at hand.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Silene alpestris grandiflora flore pleno.—This charming alpine is so fully described by its name that little need be said of it beyond the fact that it is calculated to become one of the most popular of rock garden subjects. It is 6 inches or so high, the double, pure white flowers about half an inch across, and produced with the same abundance and profusion as in the typical species. Quite an acquisition to first-class alpine and a gem withal. The purity of its shroud of blossoms is reflected by a carpet of shining green leaves. It is quite the best new alpine of the year. Exhibited by Messrs. R. Tucker and Sons, Oxford, and by Mr. G. Reuthe, Keston, Kent.

Delphinium Henri Moissan.—The flowers are large, semi-double, reddish violet or purplish in colour, and framed into a handsome spike. From Messrs. Blackmore and Langdon, Bath.

Sweet Pea Robert Sydenham.—A very beautiful waved variety of deep orange salmon colour. The best of its class we have ever seen. The blooms are large and well placed on the stems. From Mr. Thomas Stevenson, Addlestone.

Sweet Pea Royal Purple.—The name is not quite colour descriptive, but as an approximation there-to readers will get a good idea of a very fine and distinct variety.

Sweet Pea Dobbie's Orange.—A most brilliant flower, and a variety of merit and distinction. The individual flowers are very large. These came from Messrs. Dobbie and Co., Edinburgh.

Carnation Scarlet Glow.—A very handsome and shapely border variety of brilliant scarlet hue, the petals of very firm texture. We regard this as one of the best scarlets yet raised. From Mr. C. Blick, Carnation specialist, Hayes, Kent.

Rose J. F. Barry.—Said to be a sport from Arthur R. Goodwin. In any case it is a charming variety, rich golden yellow in the centre and white tipped on the outer petals. It is obviously a free and profuse flowering variety, and promises well as a garden Rose. Shown by Mr. G. W. Piper, Uckfield.

Rose Princess Mary.—A single-flowered crimson of considerable colour richness. Indeed, in this respect it is one of the most brilliant we have seen. From Mr. Elisha Hicks, Twyford.

Carnation Bedford Belle.—A Perpetual-flowering variety of delicious fragrance and that shade of salmon pink which engenders popularity. The flower is of medium size, shapely, and in its class probably unique for its rich Clove perfume. Raised and exhibited by Messrs. Laxton Brothers, Bedford.

Pæonia Golden Harvest.—This is a double pink-flowered sort, and we take the name as suggestive of the money an acre or so of such a beautiful variety would bring to the commercial grower. From Messrs. Bath, Wisbech.

Polystichum minutum undulatum.—Those who know the typical species will realise the importance of the new-comer as indicated by the varietal name. It is very beautiful and distinct. From Mr. J. Fraser, Uchelet, British Columbia.

All the foregoing were shown before the floral committee of the Royal Horticultural Society on the 16th inst., when the awards were made.

A USEFUL FLOWERING CURRANT.

(RIBES GORDONIANUM.)

THIS Flowering Currant is not so frequently met with as the commoner *R. sanguineum* and its varieties, and is not so showy or free-flowering, yet it is a valuable shrub for the mixed border.

THE NEW DOUBLE-FLOWED PÆONIA GOLDEN HARVEST.

It is of garden origin, a hybrid between two well-known species, viz., *R. sanguineum* and *R. aureum*, the well-known and commonly called Buffalo or Missouri Currant. It forms a dense, spreading bush, and the flowers are a very pleasing and unique colour, a shade of terra-cotta red, and are darkest on the outside, thus making the racemes, which are fairly long, very conspicuous before the individual blooms open. In foliage the parentage is entirely distinct, *R. sanguineum* having tomentose foliage, while *R. aureum* has decidedly glabrous, pale green leaves, and the hybrid is intermediate, resembling *R. aureum* in the shape of the leaf. For vase decoration it is a good shrub, as the sprigs last well in water, are showy and distinct. E. BECKETT.

Aldenham House Gardens, Elstree.

DAFFODILS IN NEW ZEALAND.

THE notes on "Daffodils in New Zealand," which appeared in *THE GARDEN* last September, were intended to interest your English readers in the progress New Zealand is making with the Narcissus, and also with the object of eliciting comment and information on the subject from other growers, for I am sure that among them there must be a large fund of interesting experience and knowledge, which each individual grower would like to share. It seems a round about way of obtaining such information, by means of an English paper, but we have not in New Zealand a gardening periodical, or any newspaper taking a lively interest in horticultural matters, with anything like a general circulation through the Dominion. However, *THE GARDEN* is a very popular medium, and by availing ourselves of it we effect the double purpose of reaching home and Colonial readers at the same time.

I have just read the letter of Mr. Frank Mason of Feilding in your issue of February 21 last commenting on my notes, and am very pleased he has let me down so lightly with regard to my ignorance of Wellington growers, which I admit, but do not wholly regret, since it brought forth his letter, and I hope will be but one of many such. Since I penned my notes my knowledge of Southern doings has expanded, for I have made the acquaintance of Mr. A. E. Lowe of Tai Tapu, Christchurch, who came to Auckland to act as judge at our show last September, and Mr. Joseph Weightman of Awahuri, whom I met at the Cambridge Show the same month. The latter staged there some of his early flowering seedlings, and I can fully endorse Mr. Mason's opinion of his tridymus varieties. I secured some of them to bring to Auckland for our Daffodil Conference, but unfortunately they did not last long enough. The early trumpet seedlings shown, which he told me were mostly the result of his initial sowings of seed from chance crosses, were, I thought, lacking in finish and refinement; but I was much struck by the robust strength they all showed, demonstrating that the soil and climate of Awahuri are eminently suitable for Daffodils.

In conclusion, may I reiterate the wish that other New Zealand growers, especially those South of Auckland, will take advantage of your columns to let us know how the culture of our spring favourite progresses from here to Invercargill? I understand we are to have an article on this subject in the next issue of "The Daffodil Year Book," but that will not be published for some months to come, and I prefer the homeopathic principle of "a little and often."

Auckland, New Zealand. F. E. GRINDROD.

GARDENING FOR BEGINNERS.

FLOWERS IN OLD BARRELS.

THE accompanying illustration shows an old barrel planted with suitable subjects and forming a picturesque addition to my garden. A rough wooden pipe was made 3 inches across and square-sided, and the length was nine-tenths of the height of the barrel, and stood upright in the centre after being pierced with holes. This was to ensure water reaching all parts, and in dry weather it must be often filled up. Soil was filled in between the pipe and the sides, with crocks and a few turves in the lower third. The plants were inserted as the soil reached the level of the holes cut in the sides of the barrel.

Saxifraga umbrosa (London Pride), *Cerastium tomentosum* (Snow in Summer), and a hardy *Geranium* grew and flourished exceedingly. The *Saxifraga* can be seen in full bloom now, and the *Cerastium* just shows round the edge on the right. A *Campanula* and some Wallflowers (on the top) sprang up of their own accord; the latter were the finest in the garden. I have just cut off the bloom, hoping they will flower again later. The *Campanula* is not yet due to show buds. On the top I have also seedlings of Canary Creeper, which will run up three sticks slanted over the watering pipe in gipsy tripod fashion, and a *Campanula garganica* is thriving, its roots being protected by large stones. These are necessary, as otherwise the soil at the top gets very dry in sunny weather.

On the ground round the base I had Forget-me-nots and Wallflowers. I cleared them away just before the photographer came, so as to make the picture less confused; but they are essential to complete the beauty of the real thing. Three large, healthy bosses of *Sedum grandiflorum rubrum* (red Stonecrop) can be noticed, which will come into bloom later and last till November; so three seasons' flowers are ensured. The *Cerastium* and *Saxifraga* were green and pretty all the winter.

Finchley, London, N. M. W. S.

AN OLD BARREL PLANTED WITH HARDY FLOWERS IN A LONDON GARDEN.

RAISING PLANTS FROM SEEDS AND CUTTINGS IN FRAMES.

WE are persuaded that the raising of plants from seeds and cuttings claims the serious attention of so many of our readers that we gladly comply with the requests we have received to deal with the subject. So far as the raising of annuals and other plants intended for use in the present summer bedding is concerned, the moment is late. At the same time, the amateur's frame is so constantly in request that hints on management of both the frame and its occupants are serviceable at any season. In the first place, we must differentiate between the cold frame and the manure frame or hot-bed, since both have their separate uses, and should not be confounded the one with the other.

The Cold Frame.—During the spring months, more particularly of April and May, the cold frame

is especially valuable for the hardening off of bedding plants, *Lobelia*, *Ageratum*, *Heliotrope*, Ivy-leaved and Zonal *Pelargoniums*, and other such plants rooted and potted in the previous autumn which have had their winter quarters in the greenhouse. In early autumn the same frame would be in request for cuttings of *Violas*, *Calceolarias* and *Pentstemons*, while possibly also affording shelter to *Echeveria*, which is much used as an edging plant. For such cuttings it is important that the bed of soil be raised fairly high, say, to within 8 inches of the glass. This will promote and retain dwarfness in the young plant, and that degree of sturdiness, too, so essential to subsequent success. The raised cutting-bed will also afford drainage, and, in conjunction with intelligent ventilation, keep damp at bay.

such a frame is in every way excellent for starting tuberous *Begonias* or *Dahlias* from which cuttings may be required. Tomato, Cucumber or Vegetable Marrow seeds may also be sown. By securing two or three loads of stable manure—a scarcer commodity in these days than formerly—turning it over occasionally to dispel rankness, moistening any dry parts meanwhile, it will be ready for making up in a fortnight or so. It should be made 18 inches wider than the frame at all points, and, when completed, a 2-inch surface covering of Cocoanut fibre or sifted leaf-mould should be given inside the frame. In a day or two the frame will be available for use. Cuttings will need careful watering and shading. A watchful eye must be kept so that an excess of steam does not collect. This with strong sunlight is dangerous. Cuttings of the before-named subjects require free supplies of water and root quickly. *Phloxes*, *Chrysanthemums* and *Pentstemons* should be early removed after rooting, or they will become drawn and weak.

Raising Seedlings.—The chief dangers to these in such a frame are thick sowing, over-watering, too much soil covering, and delay in pricking off. The first and last militate against success by producing a thin, lanky growth, and plants of the annual class, *Schizanthus*, *Clarkia*, *Delphinium* and others, rarely recover if once they become drawn. Here the amateur or beginner should remember that a dozen nicely grown *Schizanthuses* are better than fifty lean specimens. The former are the more readily produced by sowing three or four seeds in a 4-inch pot, subsequently reducing the seedlings to one plant, and removing its point of growth when 2 inches or so high. This allows of the whole space of the pot and the soil, too, for a single plant. Subsequent stopping will promote bushiness, and an early shift into a 6-inch pot will do the rest. Earlier sowings of this plant in a cold frame will give good results for bedding, observing drier treatment generally. The *Schizanthus* does not usually transplant well; hence pot-raised plants as suggested are the best.

The Frame.—But while thick sowing and the other things named are sources of danger and great drawbacks to success,

there is an almost equal danger in the frame itself. The frame should be clean, well painted or white-washed. The covering lights should also be scrupulously clean. Light is an important factor to good growth, and may be unduly withheld owing to dirty glass or small squares of glass. The use of small pieces of glass is wrong and bad, and should not be countenanced. Each in its way obscures light, and a thin, meagre growth results. Then, the surroundings of the frame are often at fault, trees or buildings obscuring the light so much needed by the plants. These are some of the things to avoid, some of the things which cheat the beginner out of the successes which should be his, if one might judge of the assiduity and zeal with which he pursues his way.

Avoid frequent sprinklings of water overhead. One good watering when the cuttings are inserted should last for a fortnight. **The Manure-Bed Frame** has a greater value than the cold frame, in that in it may be raised all manner of half-hardy subjects from seeds. For example, *Aster*, *Stock*, *Phlox Drummondii*, Tobacco Plants, *Ageratum* and others may be raised in this way; while cuttings of *Lobelia*, *Heliotrope*, *Chrysanthemum*, *Verbena*, *Fuchsia*, herbaceous *Phlox* and similar plants will often root with greater certainty in such a frame than in the greenhouse. One reason of this is that they revel in the slightly ammonia-charged atmosphere, the uniform warmth and moisture arising from the manure-bed being also congenial to their well-being. Then, again

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Strawberries.—No time must be lost in securing sufficient young plants for next season's forcing. Layers should be carefully placed in small pots, which may be half plunged between the rows of plants. When these are sufficiently rooted, they may be removed to some convenient spot near the potting-shed until they are ready for potting into 6-inch pots.

Tomato Plants.—Pits from which bedding plants have been removed may now be planted with strong Tomato plants, in preference to planting in the open garden. If confined to single stems, they may set a few trusses of fruit by the middle of August, when the lights can be replaced in order to ripen the crop before the season is too far advanced.

Plants Under Glass.

Tree Carnations.—Plants which were struck in February will now be ready for potting into 6-inch pots. Later plants which are intended for flowering in the winter should be grown in a well-ventilated pit, and, if necessary, the tops may be pinched as late as the end of July. Pot firmly in good turfy loam and leaf-soil, with a sprinkling of fine bone-meal, and in well-crooked pots. Syringe lightly until fresh roots are made. When the plants become established, they may be placed on a bed of ashes in a cold pit, from which the lights can be removed during fine weather and replaced during heavy rain.

Begonia Gloire de Lorraine.—The most forward batch of plants should be neatly staked before the shoots become bent. If large plants are desired, a number of thin Bamboo tips may be placed in each pot as soon as the final potting is accomplished, and the young shoots secured as time advances. When the pots are well filled with roots, frequent applications of liquid nourishment will be necessary. Later plants, if placed in small pans or baskets, will make a good display if suspended from the roof of a warm house during the winter.

Rhododendrons and Azaleas which have finished their growth and set their buds should be placed outdoors in a position which is not exposed to the midday sun. The pots may be partly plunged in a bed of ashes. Soot-water may be frequently applied, and the plants freely syringed with clear soft water during dry weather.

Cyclamen.—Young plants in 3-inch pots may be potted into 5-inch pots as soon as they are ready. The compost should consist of rich loam and leaf-soil, with a good sprinkling of rough silver sand. Place them in a cold frame on a good bed of ashes, and keep a sharp look-out for thrip, which is a troublesome pest among these plants. Light shading must be provided during sunny weather.

The Flower Garden.

Border Carnations.—These are now pushing up their flowers, and should be carefully staked before they become too far advanced. Keep the hoe at work between the plants, and give light dustings of soot during showery weather. When the flowering period is over, preparation should be made for layering young stock for next season's blooming, and these should be planted in their flowering quarters by the end of September.

Pinks.—Now is the time to propagate Pinks. If cuttings are inserted in a cold pit and shaded from strong sun, they will soon make roots, when the glass should be removed, in order to keep them hardy and short-jointed until they are planted in the autumn.

Anchusa italica.—The flower-stems of this beautiful plant should be secured to strong Bamboo sticks with as little delay as possible. The wind and rain may soon destroy them if not secured beforehand. Anchusas are easily propagated by cuttings of the roots, which may be prepared in the same way as Seakale cuttings. August is the most convenient time for the purpose.

The Rock Garden.

Spring-Flowering Subjects.—Many of these are over, and should now be trimmed to give them a tidy appearance and prepare them for the

production of cuttings for next season's stock. For instance, the choice varieties of Aubrietia, if cut over now, will soon produce cuttings, which are easily propagated in a cold frame later in the season. The same remarks apply to Arabis.

Saxifrages.—Remove old flower-spikes and thin out and top-dress the plants as soon as possible. By these means young stock will be available for future plantations.

Plants in Exposed Positions should be carefully watered during dry weather, and this must be applied through a fine rose to prevent washing the soil from the roots of the plants.

The Kitchen Garden.

Planting Autumn Broccoli.—There should be no delay in planting early Broccoli. The ground for this crop can hardly be too rich, as the plants will not be subjected to any severe weather before the crop is cut. In planting late Broccoli, the situation chosen should be open and the soil not too rich, or many of the plants may die during the winter. All winter greens ought to be planted as soon as the land becomes vacant, and it should be remembered that nothing is gained by overcrowding.

Celery.—Continue to plant this crop until the required number of plants has been put out. Water freely as soon as the plants are placed in position, and never allow the beds to become too dry during the growing season.

Leeks.—The maincrop Leeks should be planted as soon as possible. The ground ought to be well enriched with farmyard manure, and the plants allowed 12 inches each way. Water freely as soon as the plants are put out.

Onions.—Spring-sown Onions should be thinned as soon as possible. Three inches apart will be sufficient for ordinary purposes; but if extra large bulbs are desired, a little more room will be necessary.

Chicory.—As soon as the plants are large enough they should be thinned to 9 inches apart. Keep the hoe at work and give light dustings of soot during the growing season.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Carrots.—There will still be time to make another sowing outside to provide some useful roots for the late autumn; indeed, in many cases this will be a necessity where earlier sowings have only done moderately well. For this late sowing it would be as well to select the Scarlet Model or Stump-rooted sorts. This sowing could be made on ground from which early Potatoes have been taken, and all that will be required to be done is simply to rake the ground over and apply a dressing of soot or wood-ashes. Should the weather be dry, it would be as well to water the rows until the plants are well above the soil.

Scarlet Runner Beans.—As these will now be growing nicely, see that they are supported in the first instance with small stakes, which will serve until they take hold of the larger ones. Should the soil be of a light nature, mulch them on each side of the row with mown grass or manure, for, as I have already pointed out, it is of the utmost importance that they do not suffer from lack of moisture at the roots, otherwise they will most assuredly fail to set the flowers.

Onions.—Where good-sized bulbs are required, the thinning out of the young plants should be completed at once. After this thinning they must be encouraged by frequent applications of manure-water, or sulphate of ammonia and sulphate of potash in equal parts.

Early Potatoes.—As the border on which this early crop was planted will be required for seed-sowing or other equally important crop, the remaining Potatoes should be lifted and stored. While doing so, select tubers for seed for next season's crop. These had better remain outside exposed to the weather for a time until they become perfectly ripened. In selecting the seed, see that each set is true to the type of the particular variety.

General Remarks.—Keep up a supply of salads by making frequent sowings of Lettuces

and Mustard and Cress. Sow the former sparingly, as it is better to simply thin them out. Every encouragement should be given to growing crops by keeping down weeds and the removal of decayed matter, and giving an occasional dressing of some approved artificial manure.

The Flower Garden.

Azaleas.—These will now for the most part have passed out of flower, and, where at all possible, the seed-vessels should be picked off and some of the stronger shoots reduced, especially among the better varieties. The plants must never be allowed to become dry at the roots, and, should there be the slightest suspicion of this, give them a good soaking of water. Afterwards apply a heavy mulch of farmyard manure, which should be allowed to remain during the season.

Brooms.—Like the foregoing, the various varieties will also have passed out of flower; but, unlike Azaleas, pruning may be more freely indulged in. There is no plant that seems to get so soon out of hand as the Broom, more particularly the lovely white variety, and, strange to say, it is just this sort that most people are afraid to prune. For some years I have cut the plants back just after they have flowered, with the best results; but this work should only be done by an experienced person.

Double Rockets (Hesperis).—These fine old-fashioned plants, which have been supplying us with such sweet-scented spikes for decoration for some weeks past, should now be cut well down to the ground; this applies more particularly to the double white and purple. They will then form fine bushy plants, which may be broken up in the autumn and replanted. I find that unless they are treated in this way, they quickly go back, and if they are not in very favoured districts they soon die out.

Begonias.—These are plants that require abundant moisture at the roots, and although the soil has been well manured, they will be all the better to have a mulching over the surface during the earlier stages of growth. There are many things that might be used for this purpose, such as leaf-mould and mowings from the lawn; but possibly peat moss litter will be found to be as good as any. If this is passed through an ordinary riddle or sieve and spread carefully over the surface, it will not be in the least unsightly.

Plants Under Glass.

Primulas and Cinerarias.—It will not be too late to make a small sowing of these useful early summer-flowering subjects to ensure a succession to those sown earlier in the year. At this season they will do better under somewhat cooler treatment, and if carefully attended to will make quite good plants before the autumn.

Humea elegans.—This elegant greenhouse plant will now be developing its inflorescence, and the utmost care must be exercised in watering. Perhaps there are no plants that resent carelessness in this respect more so than Humeas, and that in all stages of their growth. Young plants from a spring sowing will be ready for a shift into a larger pot, but on no account overpot them.

Fruits Under Glass.

Melons.—The various crops will now be in all stages of growth, and plants that are swelling their fruit should have the laterals stopped and be given abundant supplies of water at the roots. Endeavour to keep the foliage clear of red spider and mealy bug by the vigorous use of the syringe. Plants growing in frames should have the growths so regulated as to prevent the atmosphere from becoming stagnant. Unless in very favoured districts, it will not be wise to make any further sowings after this date, as during the latter half of September and the beginning of October it is difficult to keep Melons growing with any degree of success.

Figs.—The first crop will now have been secured, and the trees should be gone over and examined for insect pests. If any are found, the trees should be syringed with some approved insecticide. The second crop is usually a very abundant one, and will be required to be severely thinned to enable the trees to ripen the fruit. Give plenty of water to the roots, and if the trees are not over-vigorous, give some liquid manure occasionally.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

CARNATIONS NOT DOING WELL (Mrs. C.).—The Carnation blooms you sent were cut from weak, sappy stock; this can be easily judged by the flabby stems. Secondly, they are all suffering from the ravages of red spider. These two reasons are the cause of small blooms and poor plants. The pest is one that requires to be absolutely destroyed; all plants so affected must be burned. The buff suffused rose pink bloom is called Robert Morton; it is a border Carnation, but owing to its weak neck and weaker habit it is not what we would describe as a useful variety.

CULTIVATION OF GERBERAS (Mrs. S.).—In order to induce a good display of bloom, Gerberas need liberal treatment during the growing season. If in pots, a suitable compost may be formed of three parts of yellow loam and one part each of leaf-mould and well-decayed manure, with a fair sprinkling of silver sand. The pots must be effectually drained, as the plants need to be freely watered except during the winter months. While the above instructions apply to Gerberas when grown in pots, the plants succeed far better when planted out of doors in a warm sheltered spot. A good example of this is in front of the Orchid-houses at Kew, where some grand specimens are to be seen; towards the end of the summer and in early autumn these throw up a mass of flowers such as one never sees when they are restricted to pots. It must, however, be borne in mind that only under very favourable conditions will the Gerbera survive the winter when planted out, and it is most questionable whether it will do so in your district. When in pots, an occasional stimulant during the summer, either in the shape of manure-water or one of the many concentrated plant foods now so generally used, will assist in the production of blossoms.

BOTANICAL TOOLS AND GENTIANAS (Tim).—Try Messrs. Sutton and Sons, Reading, or Messrs. Barr and Sons, King Street, Covent Garden, for the former. The Gentian family is of so comprehensive a nature, so varied in stature and its requirements, that in a brief reply it would not be possible to refer to the many species in detail. At some future time we may be able to refer to them more fully. Some of the more fastidious species are responding to moraine treatment, and it is not improbable that for such as *alpina*, *imbricata*, *l. alba*, *bavaria* and others this will prove a more or less congenial home. For the exquisite *G. verna* some useful suggestions have been given in recent issues of THE GARDEN, and usually the plant is a success in very sandy soils or sandy peat with summer moisture. *G. acaulis*, still one of the most precious of the race, usually grows and flowers well in light sandy soils over gravel, in Heath-like soils, and in loamy soils over sandstone rock or limestone. For these carpeting and stoloniferous sorts firm planting is essential. The Willow Gentian (*G. acaulis*) is usually happy in cool woodland places; and *G. septemfida* and *G. Przewalskii*, both free flowering and beautiful, are content in cool places in very sandy loam and peat. *G. Andrewii* (the Closed Gentian) prefers moisture or very cool loam

and peat soils. We doubt your obtaining great success when growing these plants in pots, and only the more diminutive-growing species would be at all suited to the treatment. Given the soils mentioned, any so grown should be plunged in a cool spot in the open or in a bed encompassed by a perforated pipe, so that a cool base would always be assured them.

ROSE GARDEN.

ROSES AT BAGATELLE (H. V. B.).—The following are the awards given to various Roses from 1907 to 1913 by the Juries appointed to judge those sent to the Bagatelle Gardens by various raisers. Too much importance must not be attached to these awards, as several of our most successful raisers did not send their Roses for competition. 1907.—Gold medal: Marquise de Sinety. Classed Roses: Mme. E. Sablayrolles, Mme. Constant Souper, Souv. de P. Notting and Mrs. Peter Blair. 1908.—Gold medal: Rhea Reid. Bronze medals: Dorothy Page-Roberts, Mme. Second Weber, Mrs. Dudley Cross and Frau Oberhofgartner Singer. 1909.—Gold medals: Lyon Rose and Mme. Second Weber. 1910.—First-class certificate: Molly Sharman Crawford. Certificates: Mlle. Marie Mascrand, Lady Alice Stanley and Commander Jules Gravereaux. 1911.—Gold medals: Beauté de Lyon and Jonkheer J. L. Mock. First-class certificate: Viscountess Enfield. Certificates: May Miller, Walter Speed and Desire Bergera. 1912.—Non-competitive: Rayon d'Or, Sunburst and President Vignet. First-class certificate: Mme. Jules Bouché. Certificates: Frau Margrethe Moller and Orleans Rose. 1913.—Gold medals: Mme. Charles Lutaud and Mabel Drew. Non-competitive: Louise Catherine Breslau and Mme. Edmond Rostand. First-class certificate: Grange Colombe. Certificates: Mrs. Amy Hammond, Louise Lilia and Wichmoss.

FRUIT GARDEN.

PEAR LEAF MITE (Dr. W. E.).—The Pear foliage is badly attacked by the Pear leaf mite, *Eriophyes Pyri*. (See reply to "J. G." in our issue of May 23.)

INJURY TO CURRANTS (L. B.).—We suspect a beetle, a species of *Rhynchites*, is damaging your Currants, and think it would be well to spray the bushes immediately with lead arsenate.

SILVER-LEAF ON A PEACH TREE (F. J. S.).—The Peach is affected with silver-leaf disease, for which no cure is known. It is a fungous disease growing in the wood of the trees, and when once a tree is attacked, it rarely recovers. Your best plan, since so much of the tree is affected, will be to root it out and start afresh.

LEAF-BLISTER ON PEAR FOLIAGE (Mrs. K. A. K.).—The Pear foliage is attacked by the Pear leaf-blister mite, *Eriophyes Pyri*. We have recently given a short account of this pest in our "Answers to Correspondents," and recommend that when only a few leaves are attacked, they should be removed, but when many, the trees should be sprayed about the end of May with a nicotine wash, and in winter, while the trees are dormant, with lime-sulphur salt-soda wash, commonly called the Oregon wash.

LEAF-CURL IN PEACHES (W. J. H.).—The Peach and Nectarine leaves are attacked by the fungus *Exoascus deformans*, which produces the disease known as leaf-curl. It would be well to pick off all the affected shoots immediately and burn them, taking the precaution also of spraying the trees with ammoniacal copper carbonate at the same time. When once a shoot is attacked, it rarely recovers, and is of no use to the tree; it is rather a menace than otherwise. The disease is always most prevalent where cold winds have access to the tree, and on this account screening the trees from winds in early spring, and from frost, is very desirable.

MISCELLANEOUS.

VARIOUS QUESTIONS (White Horse).—Frost sometimes affects Asparagus in the way mentioned, but injury from any cause—insects, the cutting knife, &c.—might bring it about. The cause of the extremely common phenomenon known as fasciation is unknown, nor is any remedial measure known. It is usually attributed to excess of food, either local or general. The only means of keeping wasps out of a viney are: (1) Destroy all the nests in the neighbourhood. This may easily be done if the wasps' nests are traced and a small quantity of carbon bisulphide poured into them after dusk, taking care to dig out the comb next day. (2) By covering over the ventilators of the house with muslin or mosquito netting. It would be better to fumigate the *Clianthus* rather than to spray it with paraffin emulsion, and if spraying is regarded as the best method of attack, then a nicotine preparation would be safer to use than paraffin.

NAMES OF PLANTS.—Mrs. P. J., Chester.—*Saxifraga oppositifolia*.—Felpham.—*Muscari comosum plumosum*.—Subscriber.—Apparently *Sedum spurius*; cannot name without flowers.—Anne Amateur.—The flower was too far gone to recognise.—A. C.—*Lonicera involucrata*.—F. N., Woolwich.—*Heracleum villosum*, also called *H. giganteum*, a Caucasian plant belonging to the Umbellifer family.—H. J., Ozon.—1, *Sedum rupestre*; 2, *Spiraea bracteata*; 3, *Armeria maritima lauchiana*; 4, *Lithospermum purpureo-ceruleum*; 5, *Saxifraga tenella*; 6 and 7, *Helianthemum vulgare* varieties.—H. G.—1, *Lycostera formosa*; 2, *Thuja plicata*; 3, *T. orientalis*; 4, *Collomia coccinea*; 5, *Kleinia articulata* (Candle Plant).—F. E. W.—1, *Lithum pyrenaleum*; 2, *Dianthus cæsius* variety; 3, *D. deltoides*; 4, *Acœna Novæ-Zelandiæ*; 5, *Saxifraga Sibthorpii*.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THE fortnightly meeting of the Royal Horticultural Society was held at Vincent Square, Westminster, on June 16. Hardy perennial flowers were shown in profusion, and the excellent exhibits of fruit trees in pots were deserving of the highest praise.

FRUIT AND VEGETABLE COMMITTEE.

Present: C. G. A. Nix, Esq. (chairman), and Messrs. W. Bates, E. Beckett, H. Markham, A. R. Allan, F. Perkins, W. E. Humphreys, H. J. Wright, P. C. M. Veitch, A. Bullock, J. Jaques, J. Willard, W. Pope, A. Grubb and A. W. Metcalfe.

Vegetables were not extensively shown, but Messrs. Barr and Sons, Covent Garden, W.C., sent a collection that came in for a good deal of praise. In addition to Peas, Carrots, Cucumbers and Cauliflowers, there were Mushrooms, Egg Plants, and such herbs as Pennyroyal, Silver Thyme, Rosemary, Witloof and Myrrh. A silver-gilt Knightian medal was awarded to this collection.

Messrs. G. Bunyard and Co., Maidstone, showed Cherries in pots, all well cropped with their luscious fruits. The varieties shown were Elton Heart, Black Heart, Governor Wood, Werder's Early Black, Ludwig's Bigarreau, Black Tartarian, Turkey Heart, Frogmore Bigarreau, Napoleon Bigarreau, Waterloo and Belle of Orleans. The collection was interesting, and reflected great credit upon the cultivation given them. Silver Banksian medal.

The gold medal collection of pot-trained Peaches, Nectarines and Cherries shown by Messrs. James Veitch and Sons, Chelsea, was beyond question one of the features of the exhibition. Among the fan-trained Peaches, Amsden June was shown in grand form. This is one of the best of the early Peaches, being just in front of Duke of York, and ripens at the same time as Early Alexander. Of the Cherries, Frogmore Bigarreau is one of the best of the White Heart varieties. It was interesting to note that Guigne d'Annonay, the oldest Cherry in cultivation, is still one of the earliest to ripen, and an excellent cropper.

A silver Banksian medal was awarded to the Horticultural College, Swanley, Kent, for packed fruits.

ORCHID COMMITTEE.

Present: Sir Harry J. Veitch (chairman), Sir Jeremiah Colman, Bart., and Messrs. James O'Brien, Gurney Wilson, R. A. Rolfe, F. Sander, J. Wilson Potter, S. H. Low, F. J. Hanbury, R. G. Thwaites, T. Armstrong, A. McBean, W. Cobb, J. Charlesworth, C. H. Curtis, W. P. Bound, A. Dye, E. H. Davidson, H. G. Alexander, W. H. White, S. W. Flory and W. Bolton.

There were very few novelties on this occasion, the only one to gain an award being *Odontoglossum King Arthur*, shown by Messrs. J. and A. McBean, Cooksbridge, for which a first-class certificate was awarded.

Silver Flora medals for groups of Orchids were granted to His Grace the Duke of Marlborough, Blenheim, Woodstock, Oxon; Messrs. Stuart Low and Co., Bush Hill Park; and Mr. E. R. Ashton, Broadlands, Tunbridge Wells.

A silver Banksian medal was awarded to Messrs. Charlesworth and Co., Hayward's Heath, for a group of choice Orchids including many *Odontiodas*.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. C. T. Drucery, W. A. Bilney, J. W. Barr, F. W. Harvey, J. Hudson, R. Hooper Pearson, C. R. Fielder, J. F. McLeod, C. Blick, J. Jennings, W. Howe, G. Reuthe, C. Dixon, H. J. Jones, F. Page-Roberts, C. E. Shea, C. E. Pearson, G. Paul, W. J. Bean, J. T. Bennett-Poë, W. P. Thomson, E. H. Jenkins, W. G. Baker, W. Cuthbertson, A. Turner and J. W. Moorman.

Messrs. R. W. Wallace and Co., Colchester, displayed a goodly table of hardy plants, among which were noted *Iris gracilipes*, several pots of which were most profusely flowered; *Hypericum reptans*, a graceful trailing species with yellow flowers and reddish stems; *Iris Forrestii*, yellow, with blackish striated falls; *Pentstemon heterophyllus*, of metallic blue and violet shades; with *Campanula garganica* in blue, white and pale blue, *C. pulla*, *C. pulloides*, together with fine batches of *Verbascums*, *Ixias*, *Primula bulleyana*, *Heucheras* and other good hardy flowers.

Messrs. Barr and Sons, Covent Garden and Taplow, Bucks, had an excellent display of *Pæonies*, Spanish *Irises* in variety, *Lupines*, *Delphiniums*, the early flowering *Gladioli*, *Nepeta Mussinii* and choice *Lilies*, of which *L. regale* (*myriophyllum*) was perhaps the most pronounced.

Mr. James Box, Lindfield Nurseries, Hayward's Heath, Sussex, arranged an excellent corner group of hardy plants, among which were *Pæonies* in variety, Double White Rockets, *Delphiniums* in variety and Spanish *Irises* galore, Walter T. Ware (yellow), *Chrysolora* (golden), Snow Queen and Sweetheart (white and yellow) being among the best. *Pæonia lutea*, the yellow Tree *Pæony*, *Heucheras*, *Iris spuria*, *Wahlenbergia vincaeflora* and *Betonica grandiflora robusta* were other notable plants.

Messrs. Paul and Sons, The Old Nurseries, Cheshunt, had a beautiful table of Roses. Burning Bush (crimson), Mme. Second Weber, Lady Pirrie, Nalad (blush, with orange anthers, a new Hybrid Briar of huge size and informality), Lemon Pillar (new Noisette), Duchess of Wellington and Mme. Ravary were among the best in an excellent lot. Mme. Edouard Herriot was also charming.

Messrs. G. and A. Clark, Limited, Dover, displayed Poppies, *Pæonies*, Larkspurs, *Gallardias* and other hardy flowers.

Messrs. Thomson and Charman, Bushey, Herts, had excellent groups of Poppies, Pæonies, Geums, Lupines and other good hardy things. *Pæonia lutea splendens* is of a rich golden hue, with distinctly lobed leaves. Geum Mrs. Bradshaw (scarlet) and *Linum arboreum* (yellow) were also good.

Messrs. Stuart Low and Co., Enfield, showed some excellent vases of Carnations, Gorgeous, Princess Juliana, Baroness de Brien and Princess of Wales being excellent. Good Roses from this firm included Liberty, Rayon d'Or, Lady Hillingdon, Mrs. Charles E. Russell (deep rose pink of good form), Chateau de Clos Vougeot (deepest crimson) and Lady Pirrie, all being very charming.

Pæonies from Messrs. Kelway, Langport, were extraordinarily fine. Queen Alexandra (single white), Cendrillon (rose), Orby (crimson), Dorothy Kelway (rose) and Sir T. J. Lipton (crimson, with gold anthers) were very good. The Delphiniums from this firm were also excellent. Dusky Monarch (lovely mauve and blue) and James William Kelway (an improved King of Delphiniums) were among the best.

Mr. Amos Perry, Enfield, showed a great bank of Poppies, including Perry's Blush, Perry's White and The King (a glorious bit of colour). *Thalictrum aquilegifolium* compactum, *Abutilon vitifolium* album and Irises were very finely displayed.

Messrs. Bunyard, Maidstone, had a good display of Pæonies, of which Duchesse de Nemours (fine white) was one of the best.

Messrs. Blackmore and Langdon, Bath, showed some excellent Delphiniums. Henri Moissan (rich purple), Walter T. Ware (purple, white eye) and Mrs. A. J. Watson (deep mauve) were among the best. *Begonia semperflorens virginialis* was also fine.

Messrs. T. S. Ware, Limited, Feltham, showed Pæonies, Gaillardias, Peach-leaved Campanulas, Iris ochroleuca, Delphiniums and *Achillea alpina* in goodly numbers, the whole making a fine display.

Achillea King Alfred, said to be a cross between *A. tomentosa* and *A. Kellers*, is very free-flowering. It has primrose yellow flower-heads in abundance. It was shown by Mr. W. Miller.

Mr. Elisha Hicks, Twyford, had some good Roses, Mrs. G. Norwood (pink), Princess Mary (Hybrid Tea, single crimson, very fine) and Mrs. Charles Reed (blush) being notable flowers.

Messrs. F. Smith and Co., Woodbridge, filled a lengthy piece of tabling with Poppies, Lupines, Anchusas, Heucheras, Gaillardias, Delphiniums and other showy hardy flowers.

Messrs. James Veitch and Sons, Chelsea, had a fine grouping of *Elaeagnus reticulatus*, a beautiful white-flowered Australian evergreen shrub. The flowers are drooping, bell-shaped and minutely fringed.

Messrs. R. H. Bath, Wisbech, had a showy lot of Pæonies, *Solfaterra* (white and cream), *La Fiancée* (white), Marshal Oyama (pink, gold anthers) and Her Grace (full double pink) being excellent. Spanish Irises were very fine.

Messrs. Piper, Bayswater, displayed *Saxifraga* Cotyledon, *Wahlenbergia vincaeflora*, Mule Pinks, Iris Snow Queen, *Genista prostrata*, *Hypericum fragilis*, *Corydalis tomentosa*, *Acantholimon venustum* and *Dianthus Atkinsonii*, which were very beautiful.

Messrs. Laxton, Bedford, had some excellent vases of the fragrant pink-flowered *Carnation Bedford Belle*. It is a most charming flower.

Mr. G. W. Piper, Uckfield, Sussex, had a delightful lot of the new Rose J. F. Barry. It is one of the Pernetiana group, quite hardy, richly perfumed, golden, with white outer petals; a most charming and free-flowering variety.

Mr. Charles Blick, Hayes, Kent, displayed some excellent Carnations, Charles Blick (the pure white Malmaison), Salome (fancy), Scarlet Glow (very fine) and Cecilia (yellow) being very fine. Hylda Blick (rich deep cerise) was also fine.

Messrs. R. Tucker and Sons, Oxford, had some charming alpine on rockwork, *Saxifraga cochlearis* major, *S. caesia*, *S. tyrolensis*, *Wahlenbergia saxicola*, *W. vincaeflora*, *Onosma taurica*, *Primula littoniana*, *P. capitata*, *Campanula cenisia* alba, *C. pulla*, *C. excisa*, *C. raddeana* and *Silene alpestris grandiflora* flore pleno being some of the most charming in a fine lot.

Messrs. Wills and Segar, South Kensington, had a long table of white, blue and pink flowered Hydrangeas. They were very fine examples.

Mr. G. Reuthe, Keston, had a delightful lot of things, of which *Ozothamnus rosmarinifolius*, *Saxifraga tombeanensis*, *Silene alpestris grandiflora* flore pleno, *Saxifraga valdensis*, *Moltkia petraea* and *Geranium Traversii* (pink, with silvery foliage) were among the best. *Bruckenthalia spiculifolia* (pink trusses on Heath-like stems) was very charming.

The Lissadell Bulb Farm, Sligo, sent *Primulas beesiana*, *bulleyana*, and the hybrids *Alannah* and *Ashore* (*bulleyana* × *beesiana*), differing in the shades of red and orange.

Messrs. John Waterer, Sons and Crisp, Limited, Twyford, had some beautiful alpine. *Genista humifusa*, *Potentilla nitida* alba, *Lewisia Howellii* and *Trollius yunnanense* were excellent. *Lewisia rediviva* was also on view. A fine table of herbaceous plants was also displayed.

Mr. Walter Easlea, Eastwood, had a few choice Roses, Cherry Page being very charming. *Rosa Moyesii* from China was also noted.

Messrs. George Jackman and Sons, Woking, had a lovely grouping of Pink Elsie, a pink-flowered variety with crimson base. A large exhibit of herbaceous flowers also came from this firm.

Mr. Engelmann showed Carnations in his usual style.

Mr. G. Ferguson, Weybridge, had a fine table of Delphiniums, his mauve-coloured Mrs. Bernard Crisp being excellent.

Mr. L. R. Russell, Richmond, had a table of alpine and hardy plants arranged on rockwork.

Mr. Maurice Prichard showed Iris spuria, *Hemerocallis luteola*, *Lavatera Olbia*, *Wahlenbergia vincaeflora* and other good flowers.

A superb gathering of Sweet Peas from Mr. James Box attracted much attention. They were very finely grown.

Roses from Messrs. Frank Cant and Co., Colchester, were excellent. Diabolo (crimson), Irish Elegance, Una (white) and Rayon d'Or were noticeably good.

Messrs. B. R. Cant and Co., Colchester, also showed Roses, Cupid (a new bedding single pink-flowered variety) being very charming. Irish Glory, Rayon d'Or and Una (white) were also good. Irish Fireflame is a rich coppery variety.

Messrs. H. B. May and Sons, Edmonton, showed a group of Lantanas, Heliotropes and Fuchsias as standards, also Verbenas in high excellence.

Mr. H. Burnett, Guernsey, had a lovely lot of Carnations, including Scarlet Glow, Triumph, Carola, Mikado, Mrs. Raphael, Marmion, Enchantress Supreme and Mrs. Clode, the last finely Clove-scented.

THE YORKSHIRE GALA.

BRILLIANT weather favoured the fifty-sixth Yorkshire Flower Show and Gala, held on June 17 and the two days following in Bootham Park, York. By a general consensus of opinion the show was one of the finest in the history of the society. The arrangements made by the secretary and committee and the expeditious manner in which the judging was completed left nothing to be desired. The weather on the opening day was exceptionally hot, and had it not been for the specially ventilated marquee—which, by the way, covered an acre of ground and was erected by Messrs. Piggott Brothers, London—it is quite certain that the cut flowers would never have stood as well as they did, to say nothing of the discomfort to visitors and exhibitors. The show must rank as the finest from a floral point of view. Never before do we remember at York such magnificent and richly coloured banks of hardy flowers, Roses, Orchids, Carnations and Sweet Peas.

STOVE AND GREENHOUSE PLANTS.

The ornamental specimen foliage plants we always expect to find at York, and Messrs. James Cypher and Sons, Cheltenham, seem to have had an unusual run of luck this year, for among other successes we noticed that this firm took first place in each of the following classes: Class 8, for the best collection of plants and cut flowers arranged for effect; Class 11, for three ornamental foliage plants; Class 12, for three Crotons; Class 15, for a table of Orchids; Class 16, for twelve Orchids in bloom; and Class 17, for six Orchids in bloom. Competition in Class 1, for a group of miscellaneous plants, is always a centre of interest. This class was keenly contested, and the result was as follows: First prize (£20), Mr. J. Pickersgill; second prize (£15), Mr. William A. Holmes; third prize (£12), Messrs. R. Simpson and Son; fourth prize (£10), Mr. F. H. Ward; and fifth prize (£8), Mr. T. M. Petch. The following awards were also made:

Special large gold medal to Messrs. Cypher and Sons for a group of stove and greenhouse plants.

Large gold medal to Messrs. Backhouse for Roses and greenhouse flowers.

Large gold medal to Messrs. Mansell and Hatcher for a superb collection of Orchids.

Gold medals to Messrs. Charlesworth and Co. for Orchids, and Mr. R. C. de G. Vyner for Cacti.

Large silver medal to C. E. Simpson, Limited, for floral designs and flower display.

Silver medal to Mr. H. N. Ellison for Ferns and Cacti.

Silver-gilt medals to Messrs. Batchelor and Sons for rare Ferns, and Messrs. Peed and Son for Gloxinias.

ROCK GARDENS AND HERBACEOUS FLOWER.

Although the rock gardens make an imposing feature at York, there is, nevertheless, no special class devoted to this interesting phase of gardening. It is curious to note that Class 2, for a group of hardy plants and flowers, has come to be regarded as a class for rock gardens, although the schedule does not say a word about rocks or alpine plants. It is truly surprising to observe the great advances made in rock garden exhibits in the past few years. The whole of one end of the spacious tent was filled with rock gardens, all of them beautifully arranged and planted with flowering alpine. The grand old weather-worn and often moss-grown stone from the Yorkshire moors is in no small measure responsible for the delightful effects produced. Messrs. Broadhead and Son had a truly charming rock garden, through which ran the replica of a dried-up bed of a mountain stream. Bold masses of the Himalayan Cowslip, *Primula sikkimensis* and *Saxifraga* Cotyledon pyramidalis created drifts of colour that were perfectly in keeping with the well-arranged rock garden. A large silver-gilt medal was awarded to this exhibit.

As usual, Messrs. Backhouse and Son, Limited, York, were well to the fore among the exhibitors of rock gardens. A small stream trickled down between a rocky bank into an informal Water Lily pool at the base. Hart's-tongue and other hardy Ferns grew naturally among the rocks on either side of a little stream. *Ramondia pyrenaica*, alpine Pinks, hardy *Primulas* and *Saxifragas* in variety were all shown in great profusion. This admirable rock garden was awarded first prize in Class 2. Mr. S. Pickering, Clifton, York, was second, but the arrangement was rather formal, with a little fountain playing in the centre. This exhibit was lacking in artistic touch, and the plants were of a common type. Messrs. Artindale and Son, Nether Green, Sheffield, were third, but here herbaceous plants formed the great feature—as, indeed, they should, according to schedule. Mr. T. H. Gaunt, Farsley, Leeds,

was fourth with a very creditable exhibit of rock plants, in which *Lilium rubellum*, *Dianthus neglectus* and *Androsaces* were shown in grand form.

Mr. Clarence Elliott, Six Hills Nursery, showed a number of beautiful alpine flowers, for which he secured a large silver medal. *Campanula pusilla* Miss Willmott, with a profusion of silvery blue bells, was greatly admired.

Messrs. Kent and Brydon, Darlington, were awarded a large gold medal for a beautiful rock garden that was a near approach to Nature. The interesting *Meconopsis paniculata*, with reddish purple petals and golden anthers, was well shown, as well as a number of rare *Primulas* suitable for the rock garden.

Hardy flowers were to be seen on all sides. The tall and stately spikes of *Eremurus robustus*, mingled with *Verbascums* and *Delphiniums*, made one of the features of this great exhibition. Oriental Poppies, too, were far more in evidence than usual. Princess Ena and Jenny Mawson were shown in great numbers. Hardy Lilies, again, were represented, and magnificent effects were created with *Lilium umbellatum*.

Messrs. Wallace and Co., Colchester, had a beautifully arranged group, with *Heucheras* and *Erigerons* in the foreground and *Delphiniums* and *Eremuri* in the centre. A good number of hardy Lilies, including the beautiful *Lilium monadelphum szovitzianum* and *L. dauricum* luteum, were admirably represented. Large gold medal.

The following medal awards were also made:

Gold medals to Messrs. R. H. Bath, Limited, for Pæonies; and to Messrs. Kelway and Sons for Pæonies.

Silver medals to Messrs. Rich and Co. for cut flowers.

Messrs. Godfrey and Son for Canterbury Bells; Messrs. Longster and Son for herbaceous plants; Mr. J. W. Miller for hardy perennials; and Mr. W. R. Tanner for Violas.

Large silver-gilt medals to Messrs. Dickson, Limited, Chester, for cut flowers; Messrs. Gunn and Sons for Phloxes; Mr. G. Yeld for Irises and hybrid Lilies; Messrs. Blackmore and Langdon for Delphiniums; and Messrs. Cocker and Sons for herbaceous cut flowers.

SWEET PEAS.

Messrs. E. W. King and Co., Coggeshall, Essex, struck out with an entirely new arrangement with arches and pillars. Visitors were able to walk in and around this exhibit with ease. The varieties Hercules, Rosabelle and Anglian Orange were perhaps the pick of a very wide selection of varieties. Gold medal.

A gold medal was awarded to Messrs. Hobbies, Limited, Dereham, for a representative collection of the best varieties, of good quality.

Messrs. Dobbie and Co., Edinburgh, had a grand lot, which gained for them the high award of a large gold medal. Orange-coloured varieties were conspicuous, and included Thomas Stevenson, Edrom Beauty, Inspector, Dobbie's Orange and Melba.

Messrs. Dickson and Son, Belfast, were awarded a gold medal for a truly delightful lot of Sweet Peas.

A comprehensive collection was staged by Messrs. Bide, Farnham. Phyllis Bide (orange) and Kathleen (crimson) were conspicuous in a very fine lot, for which a gold medal was awarded.

Miss Hemus was awarded a silver-gilt medal for a collection of Sweet Peas.

GROUPS OF VEGETABLES.

Messrs. Sutton and Sons were deservedly awarded a large gold medal for an exquisite collection of flowers and vegetables of excellent quality and perfect arrangement. The Melons were remarkably good, especially the varieties Universal, Emerald Green and King George.

A large gold medal was also awarded to Messrs. E. Webb and Sons, Wordsley, Stourbridge, for an exhibit comprising *Begonias*, *Calceolarias*, *Gloxinias*, *Schizanthuses*, *Primulas*, Sweet Peas, Melons, Tomatoes, Cucumbers and other vegetables.

Messrs. Carter and Co., Raynes Park, staged one of the most attractive exhibits of vegetables and flowers that we have seen from this well-known firm. The produce was of the finest quality, and a large gold medal was deservedly awarded.

CARNATIONS AND ROSES.

Messrs. Young and Co. were successful in gaining a gold medal for a superb lot of Perpetual-flowering Carnations, which were staged in a masterful way.

In Mr. A. F. Dutton's gold medal collection from Iver, Bucks, we noted Mrs. C. F. Raphael and Marmion, two of the best Perpetual Malmaisons in cultivation.

Messrs. W. Cutbush and Son, Highgate, London, are to be complimented on the perfect arrangement of their large gold medal exhibit of Carnations, Hydrangeas and weeping standard Roses.

A silver medal was awarded to Mr. G. Prince for a choice lot of Roses, in which Juliet and Mme. Ravary were shown in splendid form.

In Class 30, for a decorative table of Roses in pots and cut blooms, Messrs. W. and J. Brown were first, and gained a large silver-gilt medal for a grand lot, which, however, did not stand the heat of the day very well; neither were they labelled. Mr. G. Prince, Oxford, was second, and his magnificent blooms of Juliet came in for a great deal of admiration.

For a collection of Roses grouped for effect, Mr. W. Todd, York, was first, and his ramblers were very fine.

The following awards were also made:

Large silver-gilt medals to Messrs. Stuart Low and Co. for Perpetual-flowering Carnations; and Messrs. W. and J. Brown for Roses.

Silver-gilt medals to Mr. C. Engelmann for Carnations; Mr. W. Lawrenson for Carnations; and Messrs. Artindale and Son for Violas and Carnations.

A first-class certificate of merit for new seedling Roses was granted to the Rev. J. H. Pemberton.

THE GARDEN.

No. 2224.—Vol. LXXVIII.

JULY 4, 1914.

NOTES OF THE WEEK.

The National Rose Society's Show.—We would remind our readers that the Rose show of the year is to be held, under the patronage of Queen Alexandra and the auspices of the National Rose Society, on Tuesday, July 7, from noon until 7 p.m. It will, as usual, be at the Royal Botanic Society's Gardens, Regent's Park, London, N.W.

The Golden Heather.—There are many varieties of our common Ling (*Calluna vulgaris*), ranging from loose, straggling sorts to some of quite a dense moss-like growth, some with white flowers, others rich crimson, and others, again, that are double. The golden-leaved variety forms a low-spreading mass, which is now very pretty, suffused with a bright golden tint, which as the summer advances becomes tinged with bronze. It is rendered additionally effective when in proximity to some of the darker kinds, and supplies a shade of colour not found in the blossoms of any of them.

Rose American Pillar.—We were rather surprised not to hear this beautiful climbing Rose mentioned at the Rose Conference held in connection with the Anglo-American Exposition at Shepherd's Bush last week. We think it is one of the most beautiful of all the Roses that have come to us from the United States of America, and at least one plant ought to be in every garden in the British Isles. It has a remarkably vigorous habit, and produces its charming deep pink, white-centred single flowers with a lavishness that is only equalled by Blush Rambler. Yet the speakers at the conference, if memory serves us aright, did not mention it. A report of the conference, when such an excellent discourse was given, and so few people were present to hear it, appears under the heading of "Societies."

The Canterbury Bell (*Campanula medium*).—This is one of the gayest of our flowers at the present time, and is a plant for all gardens, whether large or small, for it may be used with good effect as a border plant, in a large bed, or as a pot plant. In all cases it is very decorative. If the old flowers are continually picked off, the plants will remain in bloom for a much longer period than they would do otherwise. When the plants are over, their place may be filled with summer-flowering *Chrysanthemums*, and a gap thus prevented. If seed of Canterbury Bells for next year's display has

not already been sown, it should be put in without delay.

Snow in Summer (*Cerastium tomentosum*).—This well-known plant, beautiful in flower and foliage, finds a home in almost every garden. Frequently it is seen making charming edgings to pathways in cottage gardens, while it is equally at home in the rock or wall garden. It is readily increased by division, or from cuttings inserted in the open in either sandy or loamy soils. Cuttings should be taken soon after flowering and placed in a shady position. This plant is commonly known as Snow in Summer by virtue of the masses of white flowers borne over its silvery grey foliage. It is one of the least expensive plants, but it never

A native of Mexico, it has been grown in European gardens since 1841; but it has never been common in the British Isles. A shrub reaching 8 feet or 10 feet high in a state of Nature, it is smaller here, rarely attaining 6 feet, even against a wall. Its evergreen leaves are oval in shape and about $1\frac{1}{2}$ inches long, while the rosy red flowers are tubular, each nearly 2 inches long, borne from short growths from the buds on the previous year's wood. It thrives in light, warm, loamy soil, and is increased by cuttings.

A Beautiful Iris.—What a beautiful plant *Iris Monnieri* is, with its charming yellow flower, which is bold in all its parts, and carried on a spike that shoots up after the manner of that of *Iris ochroleuca*! We recently saw it growing on a large border mixed with various shades of blue *Delphiniums*. The combination was very striking, and suggested what a conspicuous bed the two would make if mixed.

Two Beautiful Annual Sedums.

Among the many beautiful Stonecrops there are one or two annual kinds that should be included. *Sedum annuum* and *S. cæruleum* are two of the best for the rock garden, both being perfectly hardy. They are often overlooked—why, it is difficult to understand, unless it is because they are not very well known. They give little trouble apart from sowing the seed, and although on dry soils they will often reproduce themselves annually, they never become weeds. At the present time they are a mass of flowers, from seedlings that have stood the winter in the open. Seed sown in spring will come into bloom later.

The Spanish Broom (*Spartium junceum*).

Like many other members of the Leguminosæ family, the Spanish Broom is able to withstand drought better than the majority of plants, and is, therefore, a valuable plant for dry soils. At the present time it is one of the brightest of our shrubs, being profusely laden with its large, bright golden yellow flowers on its dark green, Rush-like growths. Owing to its making few fibrous roots, it is very difficult to transplant when large, so that it should be planted in its permanent place while it is young. Another point to bear in mind is that it should be cut back when young to make it form a compact bush, otherwise it is inclined to get rather rough

CERASTIUM TOMENTOSUM, OR SNOW IN SUMMER, CLOTHING A ROCKY BANK.

fails to produce quantities of flowers in early summer. This *Cerastium* can be purchased very cheaply, and quickly makes sufficiently large plants to produce a good effect. The accompanying illustration serves to show that expensive plants are not always necessary for beautiful results.

Abelia floribunda at Kew.—A plant of this pretty species has been flowering well against a sunny wall at Kew, every branch being wreathed with blossom. It is at the same time the most beautiful of the *Abelias*, and one of the most tender. Even in the South and South-West Counties it requires the protection of a wall, while in colder places it is hardly a shrub for outdoor culture at all.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

White Ointment Roses.—I am sending some of the White Ointment Roses, which still continue to flower profusely, though treated with "whole-some neglect" as to pruning, mulching, watering or any kind of attention for the last ten years. Can any modern Roses do the same or vie with these in fragrance?—ANNE AMATEUR. [The Rose which you designate under the above name is one of the varieties of *Rosa alba*, probably *Belle de Segur*. They are, as you say, a delightful group and very fragrant; but, of course, after June there are no more blooms until another year. We love these old Roses, and should like to see them more generally grown, and feel sure they would repay anyone to give them good culture; but we should not plant them in small gardens in preference to the many beautiful modern

magnificent rows measuring in all nearly 200 feet, composed of the finest and newest varieties, which would prove a floral feast in the course of five weeks. The gardens do great credit to the exquisite taste of Mrs. Cecil DePree and the skill of Mr. Hunt, the gardener.—HORTUS.

Mildew on Roses.—The note (page 304) by Mr. P. L. Goddard is opportune, because mildew is one of the worst pests Rose-growers have to deal with. I have tried many so-called remedies, some of which check the spread of the fungus considerably; but at last I have come across a preparation named *Seride*, made by Messrs. Gleeson and Co., Watford, which is effective, and in a rapid manner too. All Rose-growers know that *Crimson Rambler* is more affected in its flowering than any other Rose, attacking the buds viciously—so much so that they not only are unable to open, but drop off. I have tested *Seride* on the plants and find it most effective, so much so that buds once infested are now opening properly.—E. MOLYNEUX.

WAHLENBERGIA SERPYLLIFOLIA MAJOR IN A READER'S GARDEN AT FULMER, BUCKS.

varieties that give us their blooms from June to November.—ED.]

Flowers at Saughton House, Corstorphine, Edinburgh.—A few weeks ago, being in the vicinity of Corstorphine, I paid a visit to Saughton House, the residence of Captain Cecil DePree, and on being shown round the gardens I was struck by the fine collection of rock plants grown. The notes I made may be of interest to other readers. *Primulas Veitchii*, *cockburniana*, *pulverulenta*, *Forrestii*, *denticulata alba*, *cortusoides* (four colours), *capitata*, *marginata*, *involuta* and *farinosa* were all growing and flowering profusely. I noticed that *P. Forrestii* did best on a rock wall. *P. cockburniana*, of which thousands are grown, likes a heavy loam, and Mr. Hunt informed me that it is quite perennial at Saughton House. There is also a fine collection of moraine plants grown in specially prepared beds. Many of these beautiful plants were coming into flower, and would continue at intervals for some months. Sweet Peas were also a feature.

A Beautiful Rock Garden Plant.—I enclose a photograph of a group of six plants of *Wahlenbergia serpyllifolia major* which are growing on my rock garden. The abundance of their blossom was remarkable. You will see that there were many buds still unopened when I took the photograph. The plants were put in just over a year ago in soil composed of two parts of loam to one part of peat. Limestone chips were added to the soil, and also used as a mulching. The plant seems to be a thoroughly good doer, and well deserves the very high praise which Mr. Farrer gives it in his admirable book, "My Rock Garden."—MACAULAY MORT, *Black Firs, Fulmer, Bucks.*

Buddleia variabilis veitchiana.—The border soil of many shrubberies is often found to be poor in quality, and only in exceptional cases are plants liberally manured. Some kinds of shrubs make as much progress as is desired in poor soils, and among the number the *Buddleia* above named is one of the best. Last autumn I put in a young plant eighteen months old, measuring 3 feet 6 inches

in height and 3 feet in diameter, in poor soil where strong winds buffeted it to and fro all through the winter. At the present time the plant is nearly half as large again, the young shoots being very strong and healthy. This is a suitable flowering shrub for town gardens. The flower-spikes on strong plants grow nearly two feet long, and are thickly covered in August with violet mauve blossoms. *Buddleia magnifica*, with its deep rosy purple flowers, forms a good companion.—AVON.

Sweet-Smelling Rosaries.—I am told that in some convent in Italy the nuns make beads of pounded Rose leaves, which keep their sweetness, and string them into rosaries. Can any of your readers tell me where these are to be found, as I have hitherto failed to discover the address? I am further told that it is the fashion in some English gardens to copy the nuns' example, and that it is easy to make sweet-smelling beads from one's own Roses, which can be used for a variety of purposes. If any of your readers can tell me how to set about the work, or give me any information whatsoever, I shall be very grateful.—M. L. H.

SMITHII.

When I am walking down at Kew,
I thank the kind and learned powers,
Who put the names for me to view,
Of trees and flowers.

I read beneath the Willow tree.
How exiles wept in Babylon,
And in the April Peach I see
The Persian sun.

But somewhere on a tree I found
The Latin title and therewith
A name that had a homely sound,
The name of Smith.

Since then when I those glades have trod,
I honour men I never knew,
The fellow-labourers with God
Who gave me Kew.

EDWARD SHILLITO.

Galanthus Ikariae from Seed.—The leading bulb catalogues of last autumn did not quote the beautiful Ikarian Snowdrop, as during the Turkish War it was not collected; but those who have established groups of it need not rely on the bulb merchant if they take pains to save and sow the seeds. The seed harvest of this species has been more plentiful this summer than I can remember, and from quite a small bed, not much more really than a large clump, I am on the point of sowing 1,000 seeds. They always germinate well, and I keep the young seedlings in their pans for a couple of years before planting them out in quarters that have been enriched with plenty of decayed leaf-soil. The broad, glaucous, rich green—almost Tulip-like—foliage of *G. Ikariae* renders it a very beautiful subject for pots and pans in the cold house, and outside it seems to thrive better than some of the others, even when exposed to full sun. There are numerous seedlings from it here, not yet arrived at the flowering stage, in which the mother plants were pollinated with *Elwesii* and others, including the beautiful *Imperati* var. *Atkinsii*; but as the tedious process of de-anthering was not practised, the hybridity of the resulting plants is as yet, of course, a matter of doubt.—F. H. C., Rye.

Regelio-Cyclus Irises.—It is interesting (see page 308, issue June 13) to find Mr. Jacob, even if a little late, taking to these fascinating Irises, and if he really does, he will, I am sure, have no cause to regret it. One can only wonder that he has not done so before. The reasons, I suppose, are twofold. The Regelio-cyclus forms come in early spring, when Mr. Jacob in dividing his attentions between Daffodils and Tulips, has little time left for these quaint Irises. They have not quite all the grotesque beauty of the Cushions, and therefore in this respect do not absolutely fill their places. To the cultivator, however, there is enough of beauty to warrant special care, and one has but to glance at the exquisite Mars, so faithfully reproduced on page 308 of THE GARDEN for June 13, to get an idea of one of the most beautiful of this unique hybrid race. When I first saw them in 1904, I was charmed with them beyond measure, and through the kindness of Mr. Hoog I grew a small collection of them, having both complete success and presently partial and absolute failure. So long as I kept to the "narrow way"—the lifting and annual resting which is regarded as essential—all was well, but when in utter disobedience of it I wilfully took the "broad path," the proverbial Thistles and Briars appeared, and then all was not well. It so happened that at Hampton Hill I had to deal with a very light and warm soil, and in this and a warm, sunny place I endeavoured to make these Irises a success when *permanently planted out*. More than one or two came through the first winter so well that I had great hopes of success, for they flowered well into the bargain. But the succeeding growth was not strong, and though I sheltered them with lights, throwing off all wet and roasting them for weeks, they weakened so much that a year later they dwindled away. A year or two later I tried them yet again on similar lines, with like results; and it is these experiences which have caused me to send a note upon a subject about which I have written before. Mr. Jacob says: "I believe, to do them well, cold frame culture, with the plants in the soil, is by far the best way to manage them." And he will forgive me if I bluntly say, "It is not." "The difficulty," as Mr. Jacob says, "is to prevent autumn growth," and this will come in the frame or in the open. My covered plants had exactly cold frame treatment to check growth and provide rest, but it was not enough. The only royal road to success is by a species of retarding, *i.e.*, annual lifting and resting. Nothing else appears to satisfy their needs, and nothing "prevents autumn growth," like it. Mr. Jacob says he has selected four, and intends making a catalogue "plunge" for two others to constitute half-a-dozen. But in his ultimate selection your correspondent has not "spotted" the favourite Charon, a quite unique study in old gold and bronze, that should not be absent from any collection. At a more seasonable moment for planting I hope to refer to these again.—E. H. JENKINS.

FORTHCOMING EVENTS.

July 7.—National Rose Society's Show at the Royal Botanic Gardens, Regent's Park.
Wolverhampton Floral Fête (three days). Scottish Horticultural Association Meeting.
July 8.—Flower Shows at Elstree and Camberley.
July 10.—Bury St. Edmunds Sweet Pea and Rose Show. Woking Flower Show.
July 11.—Steeton Rose and Sweet Pea Show.

PLANNING AND PLANTING THE LITTLE GARDEN.

WE would remind our readers that there is still time to enter the competition for planning and planting the little garden. We are offering cash prizes to the total value of £33 12s., as well as a number of book prizes, for the best designs sent in. The coupon this week appears on page ix. Full particulars concerning the competition can be obtained by sending 1½d. in stamps to the Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. All envelopes should be plainly marked, "Planning Competition."

SEASONABLE NOTES ON AURICULAS.

COLOURED PLATE 1497.

DURING the month of July very little top growth will be visible; but if carefully tended the plants should be making roots, and in that way prepare for their second period of growth. Every encouragement must be given by admitting all the air possible, keeping them clean, and seeing that they never become too wet or excessively dry at the roots. Where the plants occupy a sunny position, a little shade will be necessary during the middle of the day.

Seed-Sowing.—To secure a stock of any special variety, offsets must be taken; but new varieties are obtained by means of seed. I advised in a previous article the method of intercrossing different varieties, and where it has been carried out, the seed will very soon mature. Although the seed of Auriculas may be sown at any season, I always like to sow it directly it is ripe, because it germinates more regularly. It must, however, be borne in mind that Auriculas are somewhat spasmodic so far as germination is concerned, and the seed-pans ought not to be discarded after the first batch of seedlings have been removed, as others may appear at any time during the following twelve months. The ordinary seed pans or boxes may be selected for sowing the seed, and they should be filled one-half of their depth with drainage, over which is placed a thin layer of moss to ensure a free outlet for water. A mixture of loam, leaf-mould and sand should be prepared, and a fine, even surface made, on which the seed is sown. This is sprinkled rather thinly and then covered with a little finely sifted soil.

Subsequent Treatment.—The best place for the seed pots or pans is in a hand-light or small frame arranged at the base of a north wall or building. To maintain a close or damp atmosphere, very little air ought to be admitted, and the receptacles must never be allowed to get at all dry. In a month or two a few seedlings will be seen, and when they have made two or three tiny leaves they should be pricked off into pans.

T. W. BRISCOE.

The coloured plate presented with this issue depicts three of the best alpine varieties in commerce. **Golden Dustman** is perhaps the best gold-centred alpine for all-round excellence in commerce, an ideal flower of absolutely correct proportions, bearing an erect truss and often carrying twenty to thirty perfect blooms. This variety was raised by Mr. James Douglas of Great Bookham, and sent out in 1913.

Phyllis Douglas.—This very fine standard white-centred alpine is one of the best shaded flowers in commerce. The large blooms are borne very erect on stiff stems, and the plant is extremely robust.

Argus is one of the best of the old varieties. It has large blooms and abundant trusses of flowers of dark plum colour shading to vinous red, the centre being white.

We are indebted to Mr. James Douglas of Great Bookham, Surrey, for all the flowers from which the coloured plate was prepared.

THE DIANTHUSES OR PINKS.

DIANTHUSES, or Pinks, are among the choicest and most satisfactory of our garden flowers, and the species, as distinguished from the florist's Pinks and Carnations, have been steadily growing in favour, so that a short account of some of the most desirable for the garden may be of service at the present time. Unless otherwise mentioned, the following Dianthus may be cultivated in a soil of rather light and sandy character. As a rule, they prefer a sunny position. They may generally be propagated by seeds, cuttings, or pipings, which are practically cuttings, but are pulled out at a joint instead of cut across. It is well to point out that, owing to the variability of the plants and frequent hybridisation, a good deal of confusion exists regarding their nomenclature.

Dianthus alpestris.—A good Pink with rose or lilac flowers, growing about nine inches high. It is easily cultivated in the rock garden or the front row of a border. According to some, this is a form of *D. monspessulanus*. Flowers from May to June.

D. ambiguus.—This species is about fourteen inches or sixteen inches high, and flowers in July. A border species.

D. anatolicus.—The Anatolian Pink has rose flowers and reaches a height of 10 inches or 12 inches. The flowers are borne in June.

D. arboreus.—A tall, not specially attractive Pink, with clustered heads, and about two feet high. The flowers are carmine. A border plant, also suitable for the wild garden, and blooming about July. Of the same class are *D. giganteus*, rose; *D. Carthusianorum*, cherry red; *D. banaticus*, rose; and *D. Armeria*, rose.

D. arenarius.—The Sand Pink is a pleasing plant about six inches or eight inches high, with grassy leaves and fringed lilac or pale rose flowers, deeper at the base, but white in many plants. Dry, sandy soil. June and July.

D. arvernensis.—A charming flower, like a miniature *D. cæsius*, and a great beauty for the small rockery. It has small leaves and pretty pink blooms. Easily grown in dry, sunny chinks, and begins to bloom about June.

D. atrorubens.—Here we have a pretty cluster-headed Pink with blood red flowers, and about nine inches high. It is uncertain in its duration of life, and many treat it as a biennial. Dry soil in the border or rockery. The Carton variety, scarlet maroon, is very fine. June to August.

D. barbatus.—The Sweet William hardly requires mention, except to refer to a beautiful little double dwarf variety, with deep crimson flowers and only a few inches high. It is variously called Murray's Double Dark Sweet William

and *D. barbatus magnificus*. A good plant for the border or rockery.

D. cæsius.—Our well-known Cheddar Pink, which, when obtained in a good form, is one of the best. It loves a crevice of rock, especially of a calcareous nature, and is quite pretty with its pink flowers. Many poor, worthless forms exist, frequently the result of cross-fertilisation.

D. cæspitosus.—A pretty, close-growing rock or moraine Pink, not often met with. It has rosy pink flowers in summer on stems 6 inches or so high.

D. campestris.—This is another Pink we but seldom see. It has creeping branches of grassy leaves and small pink flowers, and is only a few inches high. June.

D. Caryophyllus.—This is the Carnation, and is only mentioned to remind readers that the single wild plant is pretty on rockwork or old walls.

D. corsicus, only 6 inches high, and with rose flowers, is included by botanists with *D. Caryophyllus*.

D. cinnabarinus.—In most gardens *D. cinnabarinus* is found practically a biennial. It comes well from seeds, and grows from 6 inches to 12 inches high. The clustered heads bear cinnabar red flowers in June and July. Dry soil in border or rockery.

D. cruentus.—Here we have a pleasing cluster-flowered *Dianthus*. It has deep blood red flowers on stems from 6 inches to 12 inches high, about June to August. It sometimes flowers itself to death, and should be raised from seeds. Sandy soil.

D. deltoides.—The Maiden Pink is a native plant of much beauty, and has pretty leaves and small rose flowers, borne for a long time in summer. Excellent for walls, rockeries, moraines, or the edging of the border. There are several varieties, such as *albus*, white; *glaucus*, with glaucous foliage; *superbus*, with larger and brighter flowers; and *pulchellus*, pink. *D. graniticus*, the Granite Pink, may be considered a taller and finer *D. deltoides*.

D. dentosus.—The Amoor Pink is not plentiful in gardens, though a good plant. It has large, toothed flowers of violet purple, and grows on a level spot on the rockery, surfaced with grit. Classed as a variety of *D. chinensis* by some.

S. ARNOTT.

(To be continued.)

ERIGERON ASA GRAY.

THE flowers of this new variety are of an uncommon hue—being light biscuit coloured—and borne with remarkable freedom. Few herbaceous plants are so easily grown as *Erigerons*, and they are certainly very effective when planted in masses. The variety *Asa Gray* grows about eighteen inches high, forming a perfect mass of flowers that are welcome in the foreground of the herbaceous border. This variety recently gained a certificate of merit from the National Hardy Plant Society when shown by Messrs. Artindale and Sons, Sheffield.

EXHIBITING ROSES.

HINTS FOR THE NOVICE.

AS soon as the amateur becomes thoroughly imbued with the love of Rose-growing, he is anxious to compare his skill with his fellow-grower at the shows. This spirit of rivalry is seen most prominently by those who are compelled to travel daily from the suburbs to town, and it is quite amusing, and also gratifying to the old stager to hear the chaffing going on in the train as to the merits or demerits of certain Roses.

While the experienced exhibitor will learn nothing new from the few hints penned herewith,

details for the shows that will occur later in July. A most important detail is that of disbudding. This is an operation requiring much judgment. Generally, the central bud on a shoot is retained, and all the others removed as soon as they are of the size of small peas, and even earlier; but one must be careful the central bud is perfect and not damaged by frost or insect foe, otherwise this bud should be removed and one of the best of the side buds retained. The wood-buds, i.e., those growths that start out below the bud, should be rubbed out also, so that all the strength of the shoot can be concentrated on the one bud. A plant should not be burdened with too many shoots. Three or four, or at most five, are ample. Feeding the buds may still be carried out. Good

liquid manure, made from cow-manure and soot or from sheep-manure, is as good as anything; but a good, quick-acting stimulant, such as guano, will go a long way to improve the quality of the blooms.

A number of shades should be procured ready to place over the blooms three or four days prior to the show. If a cheap article is desired, what are known as Zulu straw hats, securely fastened on to a Bamboo cane, answer very well, although there are proper shades to be had of the horticultural sundriesmen.

Some of the thin and pointed Roses, i.e., those not very double, should be tied the day before the show. This is done with a piece of German wool. Allow the outer petals to be free, but tie the heart of the bloom when in its young stage, and when quite dry. Instead of tying the wool in a knot, give it two turns and leave the ends long; then it may be tightened if necessary or released easily. These ties are kept on the blooms until the last moment.

Boxes must all be in readiness, and some nice green moss obtained to show off the blooms to the best advantage. Proper exhibition tubes are essential, those known as the "Foster" or "West" being excellent. A Rose always looks best when well raised above the moss. So many beginners seem to ignore this detail. I have seen beautiful Roses cut with short

stems and dumped down on the moss, which quite spoilt them, although, perhaps, their quality was superior to those that gained the first prize. A good deep lid should belong to each show box, and be careful that the blooms are put down low enough to escape injury by the lid. The flowers can be arranged properly when at the show.

When to Cut Blooms.—As to when the blooms should be cut, I would advocate late in the evening preceding rather than in the early morning of the show day. There are various reasons for this, one being that in the early morning most blooms look fresh, and one may be deceived when too late. Allow the blooms to have plenty of water. I would prefer to take round with me a large jar full of water and place the blooms therein immediately they are cut, allowing them to remain in the jar

THE NEW ERIGERON ASA GRAY.

it is hoped the beginner may be helped so that he may be enabled to win prizes this year. Of course, as to cultural hints, he has had to rely upon past notes, as the exhibitions are now upon us, and by the time these lines are in print the City of London Rose Society will be holding its second exhibition at the Cannon Street Hotel. I would urge all who wish to become exhibitors to join the National Rose Society, and this can be done at once by writing to Mr. E. Mawley, Rosebank, Berkhamsted, who will then send various books and pamphlets that will be of much value to the exhibitor.

To be a successful exhibitor, one must possess a goodly number of the exhibition varieties. Such varieties are listed in the National Rose Society's schedule. There is yet time to attend to various

in a cool room or cellar, as long as possible before transferring them to the boxes. Roses keep much better, even those cut for the rooms, when given plenty of water and when cut late in the evening. Referring again to the boxes, there is a standard of size set up by all societies affiliated to the National Rose Society.

A good deep box for spare flowers should be taken to the show. This ought to contain a good number of young flowers, for it is surprising how quickly the blooms develop, and often those we judge the best overnight fail at the last moment. Read carefully the standard of an ideal exhibition bloom as laid down by the National Rose Society in its schedule, and also read the authorised rules for judging as defined by the same society. This will give the exhibitor a good idea of the standard to aim at. Upon the journey to the show, keep a watchful eye on your boxes. Somehow the railway porter likes to carry Rose boxes upside down, so that the water trickles down his neck, a detail that may tend to keep him cool, but will be fatal to the Roses.

Classes to Show In.—In your first attempt at showing, do not aim too high; that is, enter for six blooms before you strive to win the prize for twelve. Be careful to have the names correctly placed, and in staging put the largest blooms in the back row and the smallest in front. When practicable, place a pale Rose next to one of a deeper colour, but do not exclude a good specimen on this account. Quality will tell with the judges, not huge, coarse blooms, but those having beauty of form and finish and purity of colour. If you enter in two or three classes and find upon arrival at the show your blooms are inferior to those of your competitors, concentrate upon one class only, and put in your best blooms, when you may get a look in, whereas, if all the classes are attempted, you may fail in all. Be careful to fill the tubes with water as soon as you arrive at the show. I have seen lovely blooms ruined by want of water which is either lost on the journey or has been absorbed by the flowers.

"Dressing" Blooms.—Do not be tempted to alter the character of a bloom. What is known as "dressing" a bloom is rightly condemned by the judges. This takes the form of turning the petals back to make them appear larger, and some of our noted growers are great offenders in this respect. When you have arranged the blooms to your satisfaction, cover them with the lid, merely tilting it a little in front to admit air, and keep it thus until ordered to remove it. Ties are kept on the blooms until the time when the bell rings to depart from the tent. Do not fail to remove the ties, as judges are not allowed to do so, and this would militate against your success. Take notes carefully of Roses that gain special medals as best blooms in the show, as generally such sorts are worth growing in quantity for exhibition. Finally, do not be discouraged if you do not win a prize. Take your beating manfully and make a resolve to grow more and give greater attention in the future, when you will find success will come. DANECROFT

VIOLAS AND VIOLETTAS FOR THE ROCK GARDEN.

IF there could be found no valid excuse for importing all the flower beauty of the Viola into the rock garden—much of it, indeed, would be better accommodated elsewhere—there is every reason for introducing that phase of it which it is calculated would show to greater advantage there than in other parts of the garden. In saying this one has particularly in mind the exquisite beauty and charm of the Violettas, that intermediate group which comes between the larger Tufted Pansies (Violas) and others like cornuta and its varieties. Of these it may be safely urged that they are peculiarly adapted for the rock garden, more perhaps because of the dainty grace and lowly stature with which they are endowed,

a considerable colour range, they are calculated to please a large number who do not judge beauty by size alone. Another item of importance in regard to these plants—it may also be said of *V. cornuta* and others—is that they flower long and continuously, affording a wealth of cool, fresh-looking blossoms long after the usual occupants of the rock garden are past and gone, and in that way making their presence felt in no uncertain degree.

Apart from the Violettas, which are a host in themselves, are others which are even more wealth-affording in beauty and floriferousness, although they are less dwarf, and it may be less dainty-looking also. I refer more particularly to such as *V. gracilis*, *V. cornuta* and their varieties, than which perhaps none are better suited to the purpose one has in mind. The rich colour masses these afford, no pen-picture could ever portray. They are essentially garden plants, and those

A SEEDLING VIOLA IN A SMALL ROCK GARDEN.

and which would appear to fit them for association with many choice things.

Then, of course, they are distinctly of the perennial class, an invaluable attribute that should go a long way to making these flowers more popular for the purpose one has in mind. It may as truly be urged, of course, that other types of Violas are strictly perennial, and quite suited to the rock garden also. What I particularly desire to point out, however, is the value of the Violettas when permanently planted, and if left alone for two, or it may be three, years they will have had an opportunity of fully demonstrating their worth. So much can scarcely be said of them if it is found necessary to disturb them each year, since in a single season only a tithe of their flower beauty will have been revealed. Veritable carpeters of the soil, though smaller in growth than some, miniature in blossom and embracing

who would see them at their best must see them within the limits of the garden. These, like the Violettas, may go on for several years, and give a good account of themselves each successive year. Some, indeed, after five or six years in one position, showed but little sign of deterioration, the plants meanwhile affording a carpet of fresh green growth long enriched and ornamented by flowers. To urge the hardiness of plants with such durative powers as this might appear superfluous, yet hardiness and longevity combined are among their greater assets.

To those who would embrace varieties of each of these I would draw attention to the following. Of the cornuta class, alba, pallida, alba compacta, Blue Gem and purpurea are all worthy of consideration. Candidly, if I were restricted to one variety of this set, the last would certainly be first—first, because of the rich imperial purple

shade, which in my opinion places it head and shoulders above the rest; and first, again, because of the good lesson I learnt from my flower-loving daughter, who, charmed with its rich colour, culled the blossoms with their 6-inch-long stalks, and, inserting them with their own leafy stems in white china bowls, produced a singularly beautiful effect. It is the only one of the cornuta class that in my opinion is capable of such high ornament in the garden and the home; hence it should have greater claims upon those who seek the dual services of so good a plant. In the *V. gracilis* set, apart from the excellent typical kind, which is worthy of all thought, the varieties Purple Robe, lutea and sulphurea should be mentioned, interest centring round the latter, while great flower beauty and richness dominates the other two.

A small set of the *Violettas* should include Rock Blue, Rock Yellow, Purity, Sweetness (white, with yellow eye), Miss G. Jekyll (yellow and

plants drop their seeds in the happiest of places, and if possible, because of the new pictures such things create, they should be left to display their worth.

E. H. JENKINS.

ÆTHIONEMA WARLEY HYBRID.

THE *Æthionemas*, extremely dainty plants, somewhat resembling a refined *Iberis*, are extremely useful and decorative subjects for hot, sunny positions in the rock or wall garden, though without perfect drainage and very gritty soil they are inclined to go off during the winter. One of the most startling novelties in this connection is to be found in the hybrid referred to at the head of this note, a reproduction of which appears below, showing a colony growing in Miss Willmott's lovely garden at Warley Place. The plant originated as a seedling from *Æ. armenum*, and forms a dense, compact bush 6 inches to

ÆTHIONEMA WARLEY HYBRID, A BEAUTIFUL ROCK PLANT WITH RICH ROSE-PINK FLOWERS.

primrose), Lavinia (lavender), Eileen (deep blue, yellow eye), Robbie Jenkins (perfect in form, white, flushed yellow, quite one of the smallest), Diana (primrose) and Gold Crest (a very profuse bloomer).

Cultivation.—In this direction the plants ask for nothing more than a moderately deep and good loamy soil, an item of greater importance being, perhaps, a cool rooting medium, though even here they are less exacting than some. In any case the higher, drier and sunnier positions of the rock garden are places to avoid, while carpeting the flatter places in the line of vision where the flowers would show to advantage. In the case of the cornuta and gracilis sections, compactness of growth may be secured by annual autumn pruning, which encourages, as it also ensures, basal growth of increased vigour. This is important. In addition, a little rich soil mulch will also assist. Occasionally some of these

9 inches in height, producing from mid-April immense quantities of flowers of a deep pink colour, which lasts well into June. So rich is the colouring of the flowers and so compact the habit that at first sight it suggests *Daphne Cneorum*, and is by far the best of the family, beautiful as many of them are. As the name indicates, this charming plant was raised by Miss Willmott at Warley, and has since received the Royal Horticultural Society's award of merit. No more showy plant could be found for a sunny spot in the rock garden or retaining wall than *Æ. Warley Hybrid*, and, given a free, gritty root-run and slight protection against winter damp, should the season be a wet one, there is no difficulty in its cultivation. Propagation is readily effected by cuttings, and the greatest effect is obtained by grouping the plants as seen in the illustration.

REGINALD F. MALBY.

SOME LITTLE-KNOWN CLIMBERS.

THE SCHIZOPHRAGMAS.

SCHIZOPHRAGMA is an Eastern genus of Saxifragaceæ closely allied to *Hydrangea*, the chief difference between the two genera, from a horticultural point of view being noticeable in the sterile flowers.

In *Hydrangea* each sterile flower is made up of four bracts, whereas in *Schizophragma* one bract only appears with each sterile flower. For many years *S. hydrangeoides* was confused with *Hydrangea petiolaris*, and plants obtained under the former name almost invariably proved to be the latter. Now, however, two species of *Schizophragma* may be procured, thanks to Messrs. Veitch and Mr. E. H. Wilson, the latter gentleman having collected and forwarded seeds to the Veitchian

firm about twelve or thirteen years ago. The two species are *S. hydrangeoides* and *S. integrifolia*. The former species was described in 1835 by Siebold and Zuccarini in the "Flora Japonica," page 58, t. 26. On several occasions it has been included in the botanical collections of both Chinese and Japanese travellers. Oldham, for instance, obtained specimens in Nagasaki as long ago as 1862. Seeds of the true plant have also found their way to this country earlier than those forwarded by Mr. Wilson, for ten years ago a good-sized plant existed in the late Mr. Chambers' garden at Haslemere. In habit it bears a close resemblance to *Hydrangea petiolaris*, for it has similar bright brown, scandent branches which climb by means of aerial roots, and the leaves are somewhat similar in shape. They are broadly ovate or, at times, almost cordate, with coarsely toothed margins, and are often from 5 inches to 7 inches long and 4 inches or more wide. They are hairy on both surfaces, particularly on the veins. The flowers appear in large, terminal corymbs, an indefinite number of fertile flowers being intermixed with a few sterile blossoms, consisting of one bract only. The bracts are white, 1 inch to 1½ inches long, and three-quarters of an inch to 1 inch wide.

S. integrifolia is a native of China. It was collected by Professor A. Henry in Szechuan, and was figured and described in Hooker's "Icones Plantarum," t. 1934, in 1890. Seeds were originally introduced to this country by Mr. Wilson during his first visit to China. Like the older plant, it has scandent branches, which bear aerial roots after the manner of the Ivy. It, however, differs widely in other respects. The leaves are ovate or ovate-lanceolate, often glabrous, but sometimes bearing a few scattered hairs on the under surface. The larger leaves are up to 8 inches or 9 inches in length and 4 inches wide.

Light, well-drained loamy soil containing leaf-mould appears to suit both plants, and they grow well against walls, on the upturned roots of trees, or on tree trunks. As they become better known they will doubtless find favour for planting against walls on account of the self-clinging habit. W. D.

ROYAL HORTICULTURAL SOCIETY'S SUMMER SHOW.

AS we go to press the great summer show of the Royal Horticultural Society is being held, by kind permission of Mary Countess of Ilchester, in the charming grounds of Holland House, Kensington. We understand that visitors to the Show will be admitted to the private gardens at Holland House each day on payment of 1s., the proceeds to go to charities. Most of the exhibits are of exceptionally good quality, Roses, Sweet Peas, Orchids, hardy flowers and trees and shrubs being dominant features. Here have been gathered together all that is best from our British gardens and nurseries, and it is to be hoped that the public will visit the show in their thousands, and so compensate the Council and the various committees for their labours in bringing together so magnificent a display. Naturally, this show is of a different character to that held at Chelsea earlier in the year, but it is none the less interesting. An exhibit that everyone ought to see is that arranged by Messrs. R. Wallace and Co., where Japanese Irises border a natural-looking pool of clear water. We have no hesitation in saying that never before have these beautiful Irises been shown in better condition in this country, and when we remember that entire plants have been lifted and transplanted from Colchester to Kensington, we do not think any praise is too high. To the Council and the various officials of the Society we wish to tender our thanks for their unfailing courtesy and help freely given to enable us to report at least the greater portion of the show.

HERBACEOUS PLANTS.

There is now on view in the historic grounds of Holland House a display of herbaceous flowers and hardy flower gardening of overwhelming beauty, one, while rich in flower colour, is more surpassingly rich in high cultural excellence and that suggestiveness which in outdoor gardening is of the greatest service. In this latter our readers will realise the finger-post, and, following it, make of their gardens things of pleasure and delight. In no department is this more true than in the Iris and water garden arranged by Messrs. Wallace and Co., Colchester, at the left of the great tent near the entrance. Here our readers will quickly find a group of a thousand or more square feet of sumptuous beauty arranged in the best of taste. We have, indeed, never seen the great water-loving Irises of Japan displayed more finely, never in such profusion or with flowers of such magnificent proportions. In colour variety there is equal richness—white, purple, violet and rose in self, or these in combination, which defy description. Certainly the gem of the whole is Morning Mist, a study in white and blue, the flowers of Oriental

splendour reaching to dinner-plate proportions. It is in every way a magnificent plant. Rosy Dawn, Mikado (white, rosy lines), Distant Mountain (white, violet veins and rosy standards) and Recumbent Dragon (purple) are among those to be noted. The water portion is approached by stone steps, with *Spiræa palmata*, the newer *Astilbes*, *Funkias*, *Trollius chinense*, *T. pumila yunnanense*, *Rodgersias* and other good plants around. In fine, it is a group of remarkable beauty, the like of which we do not remember to have seen before.

At the other extreme of the same tent Mr. Amos Perry has a remarkable *Delphinium* group, a family which he has largely made his own. The flower-spikes, shown in their hundreds, reveal superb cultural excellence, and, grouped together in large blocks, are seen to advantage. Mrs. Creighton (rich dark purple, double), Lizzie (fine pale blue single), Edric Kingscote (single blue, white eye), Midas (iridescent blue), Evelyn and King of *Delphiniums* are some of the best. In addition there is to be seen a fine run of the newer *Belladonna* types, as *Lamartine grandiflora* and Mrs. Brunton. *Lilium Roezlii* (refined orange), *Dianthus Napoleon III.*, with single *Dianthus*es of sorts, Day Lilies and other Lilies, are some of the more imposing things that must be sought out in this fine group.

In this same tent Messrs. Carter and Co., Raynes Park, have set up a superb water garden exhibit, the dominant feature naturally being a fine lot of Japanese Irises. These are arranged in bold, informal groups—just that kind of thing capable of fine interpretation in the garden, hence justifying exhibition work as a whole. Of the more conspicuous of the Irises are Albertino (white), Tokio (rose and white), Admiration (a fine rich purple with white), Morning Mist (bluish white—the greatest, from more than one point of view, of all this race) and Yvette Guilbert (purple, white veins). *Funkias*, *Adiantum pedatum*, *Spiræas* and Bamboos either back the group or margin the water, which in its turn is delightfully ornamented by Water Lilies. The grass turfed banks and the excellent execution of the whole add both naturalness and charm. Then, in a sort of annexe leading from the main exhibit and in part revealed therefrom, are Irises again, a nice lot of Bamboos in graceful plumage, together with a fine central grouping of *Campanula persicifolia* in blue and white. An excellent arrangement worthy of a great firm.

Then, in an opposite group in the same tent, Messrs. Waterer, Son and Crisp, Bagshot and Twyford, are setting up an excellent mixed arrangement of herbaceous and rockwork plants, the whole forming a pretty and effective group. In this we noted rich masses of Larkspurs, *Gaillardias*, *Primula littoniana*, *Wahlenbergia vinæflora*, *Pentstemons*, *Campanula pulloides* and a great variety of plants suited to the rock garden.

Mr. G. Reuthe, Keston, Kent, will be found showing an interesting variety of alpines, shrubs and herbaceous flowers. His finer things are *Abelia floribunda*, *Crinodendron Hookeri* (also

known as *Tricuspidaria lanceolata* and *T. dependens*—the latter, we believe, erroneously), *Rhododendrons intricatum* and *camelliæflorum*, *Ononis fruticosa*, rare and beautiful in rose pea-shaped flowers; together with *Carpenteria californica*, *Andromeda speciosa*, *Lilium philadelphicum*, *L. pomponium*, *L. Martagon* G. F. Wilson, *L. Willmottiae*, *Orchis foliosa* and a great variety of alpines. Heaths are very charming, while *Edelweiss*, *Genista* and the smaller of the rock-loving *Hypericums* are also very beautiful.

Messrs. William Cutbush and Sons, Highgate, N., are showing a fine lot of Larkspurs, Bamboos and Liliacs in variety. Phloxes, *Romneya Coulteri* and such things as *Campanulas* are being well shown.

Messrs. Barr and Sons, Covent Garden, and Taplow, will be found displaying a very fine collection of *Delphiniums* and English Irises, the latter constituting a good succession to the Spanish Irises of mid-June. These are very fine, their broad petals (falls) rendering them highly distinct. *Iris lævigata* is also much in evidence. In addition there may be seen a good array of *Iris ochroleuca*, together with Day Lilies, *Ixias*, *Calochortis*, such Lilies as *canadense*, *washingtonianum*, *pardalinum*, *Roezlii* and others.

Mr. James Box, Lindfield, Hayward's Heath, is displaying in the Upper Tent a remarkable exhibit of hardy flowers, of which cut herbaceous plants and Water Lilies in pools are the most dominant features. The group, of unusual formation, is showing two sides at the entrance and exit of the tent, and is composed chiefly of *Delphiniums* in blue and violet, with a great mass of white *Iris lævigata* in front and *Spiræa palmata* at the sides. At right and left flanks are groups of Bamboos bowing graceful plumes, while immediately beneath are stands of *Ne Plus Ultra Gladioli* mirroring both into fuller life. Centrally placed is a pool, and herein are Water Lilies at once beautiful and cooling in effect. *Gladiolus America*, G. Golden West and G. Halleyi, with the moisture-loving *Primulas*, are among those seen. Phloxes of several groups are also well shown.

Messrs. G. and A. Clark, Limited, Dover, are setting up a fine group of herbaceous plants, notably *Delphiniums*, *Astilbes*, Japanese Irises, *Wahlenbergias* and Ferns. Of the former, Rev. E. Lascelles, Alake, Nubian (a very dark form) and Queen of Spain (white and blue) are the more important. *Verbascum Warley Rose* is also finely displayed, and is certainly a good addition to this group.

Messrs. Whitelegg and Page, Chislehurst, are displaying a fine lot of *Delphiniums* in almost endless variety and excellence. *Wahlenbergia vinæflora* is also one of the fine plants to be noted in their group.

Messrs. Phillips and Taylor, Bracknell, Berks, are arranging a fine exhibit of water gardening in conjunction with Water Lilies and other suitable plants. In the latter section the newer *Astilbes* find an important place, while about and around are to be seen *Juncus zebrina*, *Acorus japonica*, *Pentstemon*, *Sagittarias* and quite a representative

display of the Marliac Water Lilies. The exhibit is very charming, suggestive and educational.

Messrs. H. J. Jones, Limited, Lewisham, are displaying herbaceous Phloxes in the highest excellence, both in the cut state and in pot-grown examples. The latter, indeed, are of great garden value. They display height, habit and those other particulars which are of such inestimable value to the amateur. The group, too, shows how these things can be hurried along; how with good, or, shall we say, intelligent cultivation, they may be presented to view in the exhibition tent quite worthy of the garden. The best varieties—it is, of course, a question of taste—are Elizabeth Campbell, salmon and white; G. A. Strohlein, scarlet and crimson; Meteor, deep pink; R. C. Pulling, deep pink, a sport from the above; Frau Ant. Buchner; Dr. Charcot, mauve; and Baron van Dedem, orange scarlet, which is perhaps one of the finest and the best. The excellence of the exhibit and its high decorative merit will, we think, appeal to all.

MISCELLANEOUS STOVE AND GREENHOUSE PLANTS.

Cannas and Zonal Pelargoniums are capitally shown by Messrs. H. Cannell and Sons, Eynsford, Kent. The former are always a brilliant feature of this firm's displays, and, as usual, they are represented by a most interesting series of varieties and in the glorious colours for which these plants are famous. Zonal Pelargoniums have for many years been kept well to the front by this firm, who have always exhibited large and handsome bunches of all that is new and choice, and on this occasion there is much to interest and please in the splendid sorts set up for inspection.

Zonal Pelargoniums are also set up by Messrs. Carter Page and Co., London Wall, E.C. This display is quite good, and includes a capital representation of the more popular and reliable kinds.

Cannas in a mixed group are shown by Mr. A. H. Cole, 326, Camberwell New Road, S.E. It is pleasing to find these plants represented by another firm. The sorts are good and the plants very interesting.

Ferns and Geraniums from Mr. A. Donnithorne, Ashburton, Devon, combine with Begonias to make an attractive display. These are to be seen in Tent No. 1, where the combined effect is quite pleasing.

Messrs. W. J. Godfrey and Son, Exmouth, Devon, in addition to beautiful Campanulas (Canterbury Bells), have a beautiful display of all species of the Pelargonium and Solanums. The Pelargoniums, which this firm have done so much to develop, are highly attractive, and they represent the various types in charming fashion. The Solanums (*Wendlandii*), too, are novel and pleasing.

Fuchsias and Zonal Pelargoniums are represented in fine form and condition by H. J. Jones' Nurseries, Limited, Ryecroft Nursery, Lewisham, S.E. Mr. Jones, who has done much to improve the Zonal Pelargonium, is showing these richly coloured flowers in excellent form and in capital variety. He has many grand novelties of the Paul Crampel type that show marked advance. Of the newer Pelargoniums the following are noteworthy: Mrs. R. C. Pulling (a giant white), Mrs. G. Lovelock (crimson scarlet), D. B. Crane (bright rose), Mrs. F. Ambrose (deep salmon self), Lottie

(rosy scarlet) and Fred Gulliver (orange red). These are just a few of the good things, of which there are many. Hybrids from *Fuchsia triphylla* are beautiful, and of these there is now a most interesting series, all deserving extended culture. The colours of these flowers are now quite comprehensive. This exhibit is arranged with a collection of herbaceous Phloxes and beautiful Campanulas.

Hydrangeas in charming variety, Fuchsias and Zonal Pelargoniums are well shown by Mr. Philip Ladds, Swanley Junction, Kent. This exhibitor, as is his wonted custom, shows plants that are well grown. Good culture is very noticeable both in the character of the plants and in the quality of the flowers, and they are set up in an attractive way in Tent No. 7.

Five hundred species and varieties of stove and greenhouse and British Ferns are exhibited in the Large Tent by Messrs. H. B. May and Sons, Limited, Dyson's Road Nurseries, Upper Edmonton, London. This is a truly beautiful display, such as we are always accustomed to see put up by this firm of Fern specialists. Taste in arrangement and quality of the various plants is paramount in this exhibit, and there is much to interest and please the Fern-lover and others. Noteworthy examples are *Polypodium Vidgeri*, *P. Knightæ*, *P. mandaianum*, *Davallia brasiliense*, *D. fijiensis*, *D. Veitchii*, *Adiantum Veitchii*, *A. grossum*, *A. farleyense*, *Lygodium japonicum* (a fine specimen, 12 feet in height), *Gymnogramma superba* (golden), *G. Mayii* (silver) and a host of remarkably beautiful examples of other species.

Messrs. J. Hill and Son, Lower Edmonton, have a superb group of stove and greenhouse Ferns arranged in the Large Tent that is a source of considerable pleasure to the thousands visiting this great show. There are more than two hundred species and varieties representing all the better well-known subjects, and the group leaves nothing to be desired. Remarkable examples of Tree Ferns and *Cibotium Schiedeii*, *Dicksonia squarrosa*, *Cyathea dealbata*, a unique specimen of *Platynerium grande* (the Stag's-horn Fern), *Polypodium mandaianum*, *Dicksonia Barometz*, *Polypodium quercifolium* (a grand specimen) and numerous *Davallias* in endless varieties are included. The group is edged with beautiful examples of tinted *Adiantums* in charming variety.

At the south-east corner of the Large Tent Messrs. W. Cutbush and Sons, Highgate, London, N., have a large group of a comprehensive character. Cannas are bright and inspiring, and there are masses of dwarf baby Roses and Carnations in charming variety. This group is finished off pleasingly with Ferns and other dainty subjects.

A large group of stove and greenhouse plants is set up by Mr. L. R. Russell, Richmond, Surrey, embracing a great variety of most interesting subjects. Among the more noteworthy in this charming group are the following: *Alocasias*, *Anthuriums*, *Marantas*, *Crotons*, *Dracænas*, *Aralias*, *Nertera depressa* (the Coral Plant), *Caladiums* and a diverse variety of other beautiful foliage. All combine to make a display worthy of this firm.

Mr. Vincent Slade, Taunton, has a number of handsome bunches of Zonal Pelargoniums set up in Tent No. 1. This grower has for many years devoted attention to these richly coloured subjects, and his exhibit on this occasion is just what we might reasonably expect of him.

The Right Hon. Colonel Mark Lockwood, M.P. (gardener, Mr. G. Craddock), Romford, makes a most attractive exhibit of well-grown Fuchsias. The displays from this source are always very

pleasing, and the character of this exhibit is distinctly beautiful and meritorious.

Streptocarpus in Tent No. 7 and *Caladiums* in Tent No. 6 from Messrs. John Peed and Son, West Norwood, S.E., are noteworthy exhibits in this great show. The former subject is represented by well-grown plants of a beautiful strain, and the latter are, as usual, shown in all their glory of rich and varied colourings. The tropical weather now being experienced suits these plants splendidly, and there is little risk of the plants suffering on this account. The varieties are very interesting and the foliage is well coloured.

BEGONIAS AND GLOXINIAS.

The beautiful exhibits of Messrs. Blackmore and Langdon, Twerton-on-Avon, Bath, are always eagerly sought after by lovers of the tuberous-rooted Begonias, as this firm's representation of this gorgeous subject never fails to attract. The blooms are to be seen in the highest degree of good culture, and such double varieties as *Lady Carew* (a lovely rose), *Princess Victoria* (salmon pink), *Lady Cromer*, *Empress Marie* (white), Mrs. James Reid, Mr. James Douglas, Lord Methuen (brilliant scarlet), *Violet Langdon* (a beautiful flesh pink), *Rose Superbe* (rose of a pale tone) and many other equally charming varieties go to make an exhibit that well maintains the reputation of this well-known firm.

Begonias and Gloxinias are set up in attractive fashion by Mr. A. Gwillim, Sidcup, Kent. This grower has a beautiful collection of the better-known named varieties, the more notable sorts being *Sidcup Beauty*, *Lady Cromer*, *Miss Ada Britten*, Mrs. H. Harris and Mrs. J. C. Gwillim.

A magnificent table group of Begonias from Messrs. Thomas S. Ware and Co., Feltham, attracts considerable attention, both on account of its quality and its representative character. This firm have done much to develop this truly gorgeous subject, and never fail to set up an exhibit that worthily maintains their position as one of the leading specialists. The plants are flowering freely and are carrying blooms showing the highest cultural skill. A few of the better sorts in this collection are the following: Mrs. Maurice Pope (charming salmon rose), *King George V.* (rich salmon of the highest quality), *Countess of Dartmouth* (cream, edged and flaked rose), *Gladys Valentine* (pale salmon), Hon. Mrs. Ronald Greville (a beautiful cream), Mrs. Andrew Tweedie (another excellent cream-coloured sort), Hon. Mrs. Maurice Glyn (apricot) and a superb rich salmon of a specially attractive kind named *Duchess of Marlborough*. Space prevents us mentioning more than a tithe of the good things in this exhibit.

Messrs. Webb and Sons, Wordsley, Stourbridge, as usual, have made a charming display in Tent No. 3. Part of their exhibit comprises Begonias and Gloxinias, and they invariably set up their display in novel and pleasing fashion. This firm's strains of these two subjects are well known for their excellent quality, and they are beautifully exemplified in the exhibits made on the present occasion. Exhibitors generally might learn much from the novel methods of staging observed by this firm, in which the different subjects are seen at their best.

Messrs. James Carter and Co., Raynes Park, London, S.W., have set up Begonias in Tent No. 3, with many other interesting greenhouse plants. They represent a good strain, and are freely flowered.

Begonias as shown by Mr. A. H. Cole, 326, Camberwell New Road, S.E., are a pleasing feature. Good, free-flowering kinds are shown, which, together with Cannas, make an attractive display.

Mr. A. Donnithorne, Ashburton, Devon, has made an exhibit in which Begonias play an important part. They are represented by an interesting series of plants that show good culture.

In No. 1 Tent an exhibit of Begonias from Mr. W. S. Edwardson, Elsdon, Sidcup, calls for special notice. As an initial effort this display is quite good. Good culture and an interesting series of varieties and types all contribute to make the display highly meritorious. The plants are very fresh and clean.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, Middlesex, have a beautiful table group of double and single flowered Begonias, in which the former very largely preponderate. The plants exhibit high cultural skill, and embrace colours that are charmingly diverse. A few of the better doubles are Sir Garnet (fine deep crimson), King George V., Lady Cromer, Snowdrop (chaste white), Hon. Mrs. M. Glyn (rich orange terra-cotta) and Margaret Gwillim (yellow).

ORCHIDS.

Messrs. Flory and Black, Slough, are showing an immense bank of highly coloured Orchids. Cattleyas form the leading feature of the group, but the gem of the exhibit is seen in the magnificent little batch of *Disa Luna*. About four dozen plants are shown, all in the picture of health. This, however, is the most easily grown variety of the genus.

Messrs. Mansell and Hatcher, Rawdon, Leeds, are represented by a grand display of *Lælio-Cattleya* hybrids, *Odontoglossum crispum* (good white forms), *Aerides odoratum*, and some special *Odontoglossum* hybrids shown for the first time.

Mr. C. F. Waters, Balcombe, Sussex, is showing Cattleyas and Brasso-Cattleyas in variety, with handsome overarching sprays of *Odontoglossums* in the background.

Mr. Harry Dixon, Spencer's Park Nursery, Wandsworth Common, is showing various *Odontiodas*, pure white *Cattleya Mossiæ Wagneri*, and a beautiful form of *Odontioda Wilsonii*, which is admired by all lovers of Orchids.

Messrs. Charlesworth and Co., Hayward's Heath, are showing a smaller group than usual, but the quality is quite up to their usual high standard of excellence.

Sir Jeremiah Colman, Gatton Park, Reigate (gardener, Mr. Collier), sends a group magnificent in colouring and staged in a masterly way. Among the features of the group are Cattleyas *gigas* King Edward VII., *gaskelliana*, and William Murray; *Lælio-Cattleyas* *canhamiana alba* and *Phœbe*, *Thunia winniana*, also *Odontiodas* raised at Gatton Park, together with *Miltonia* hybrids, including an albino form.

Messrs. Sander and Sons, St. Albans, have a group unsurpassed in the splendour of its Cattleyas, *Miltonias*, *Dendrobium Dearei* and others. On either side of the group are large banks of the magnificent *Cattleya gigas sanderiana*, shown in exceptionally good form.

It is a real pleasure to see the intensely interesting group, in which *Vandas* and *Thunias* play an important part, shown by Lieutenant-Colonel Sir George Holford, Westonbirt, Tetbury, Gloucestershire. Large specimen plants of *Cattleya gigas* carry heavy trusses of magnificent flowers, and these, like all other specimen orchidaceous

plants from Westonbirt, reflect the greatest credit upon Mr. Alexander, the well-known grower.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, Middlesex, have a gorgeous display, in which the orange-scarlet *Renanthera imschootiana* is used with delightful effect among the white spikes of *Phalænopsids* and *Odontoglossums*.

Messrs. E. H. Davidson and Co., Twyford, have a miscellaneous group worthy of special note. Among the novelties may be observed *Cattleya Vulcan* × *C. aurea*, *Odontoglossum Aireworthi* Orchid Dene variety and *Odontoglossum eximium*. The *Phalænopsids* with their drooping inflorescences of white flowers make an imposing display.

SWEET PEAS.

Holland House Show may fairly claim to be the forerunner of the open-air-grown Sweet Pea displays each season, for while various early provincial shows and also the great Chelsea exhibition are notable for their displays, these for the most part are made up largely with flowers from under glass. The Holland House Show, however, sees the various specialists in strong force with outdoor-grown blooms, and on this occasion the exhibits are more numerous than usual, and, what is still more important, the quality is very fine.

Messrs. Sutton and Sons, Reading, make a feature of their black velvet shields backed by a grey screen, and the flowers are most artistically arranged in tubes and vases. A few of the most telling varieties are *Barbara*, *King Manoel*, *Mrs. C. W. Breadmore*, *Rosabelle*, *Doris Usher*, *Margaret Atlee* (a very fine cream pink) and *Scarlet Emperor*.

Messrs. Dobbie and Co., Edinburgh, as usual, are in strong force, and without any artistic embellishments they make a marvellous display. The flowers are of very high quality, size and colour being most telling. Upon tall pillars *Rosabelle*, *Lavender G. Herbert*, *Royal Purple*, *Thomas Stevenson*, &c., are shown, these blooms being ordinary field-grown; while in vases are gorgeous examples of *Margaret Atlee*, *Hercules*, *New Marquis*, *Red Star*, *Miss Ireland* (a new cream Picotee), *Frilled Pink*, *Dobbie's Orange*, *Lady Miller*, *Horatio* (a fine dark blue), *Dobbie's Cream* and *Alfred Watkins*.

After a lapse of several years Hobbies, Limited, Dereham, have blossomed forth as Sweet Pea specialists again, and they make an excellent display of high-class blooms. A most striking feature is the new *Mrs. Hugh Wormald*, a most striking bicolor with a soft salmon standard and cream wings, the latter having quite a frilled appearance. It is quite one of the best breaks yet shown, and reminds us of a *grandiflora* seedling we saw some years ago, but which failed to survive, the nearest to it being *Anglian Fairy*, although the latter is much paler. Messrs. Hobbies' exhibit is made up with archways and pillars at the back, while the foreground is filled in with grandly staged vases. Hobbies' *Cream*, *King Manoel*, *Money-maker*, *Edna May*, *King White*, Hobbies' *Salmon*, *Mrs. C. W. Breadmore*, *Thomas Stevenson*, *Miss Knyvet* (a soft rosy salmon) and *Scarlet Emperor* are a few other notable varieties.

Another fine exhibit is that of Messrs. Alex. Dickson and Sons, Newtownards. Archways with hanging vases are a feature. Arranged upon tiers beneath are vases of all the popular varieties and many new seedlings, including a most vivid orange scarlet. *Margaret Atlee*, *Hilary Christie*

(a pretty orange bicolor), *Melba*, *Hawthorn Rose*, *Illuminator*, *Blue Picotee*, *Melody* and *Orchid* are a few other varieties that stand out prominently.

Messrs. James Carter and Co., Raynes Park, make an effective display, the stand being backed and covered by neutral grey material. Among the most telling varieties are *Doris Usher*, *Mrs. Breadmore*, *Irish Belle*, *Lavender George Herbert*, *Red Star*, *Mrs. Cuthbertson*, *Charles Foster*, *Thomas Stevenson*, *Hercules*, *Rosabelle*, *King Manoel* and *Margaret Atlee*.

A very fine exhibit is set up by Mr. James Box, Lindfield. *Edna May Improved* and *King Mauve* are magnificent, while among others one notes *Mrs. Gibbs Box*, *James Box*, *Hercules*, *Orange Perfection*, *Ella Box* and *Dobbie's Cream*, the latter being remarkably deep in colour.

Some moderately good flowers are set up by the Rev. C. C. Chalmers Hunt, William Rectory, Letchworth. *Thomas Stevenson*, *Scarlet Emperor*, *Mrs. Cuthbertson* and *Mrs. Hardcastle Sykes* are very fair examples, considering the flowers were grown quite naturally without any disbudding whatever.

Messrs. G. Stark and Son, Ryburgh, set up quite a telling group upon the ground. Pillars break up the flatness while white trellis-work is used as a background. The flowers are merely field-grown, no disbudding being done, but they are, nevertheless, very good, especially *Lord Northcliffe*, *King Manoel*, *Helen Williams* and its white form, *Elsie Edwards* (a cream-ground bicolor), *Thomas Stevenson* and *Lady Miller*.

Messrs. J. K. King and Sons, Coggeshall, stage excellent blooms, but they are somewhat cramped for space. Among the many varieties shown we noted *May Campbell*, *Mrs. Breadmore*, *Crimson King*, *Margaret Atlee*, *King Manoel* and *Charles Foster*. The exhibit is divided in two portions, which makes it less effective than it would have been.

Messrs. E. W. King and Co., Coggeshall, set up an exhibit similar to that staged at York Gala.

VIOLAS.

Mr. Howard H. Crane, Woodview, Highgate, N., sets up a representative exhibit of *Violas* and *Violettas* and, considering the great heat of late, the blossoms are fresh and attractive. They are arranged in pans of wet sand, in which they keep very well. Excellent *Violas* are *A. S. Frater* (white, edged blue), *Mrs. B. Eric Smith* (a grand yellow), *Lingii*, *May*, *Moseley Perfection* (all good yellows), *Swan* (pure white), *Cygnets* (creamy white), *Daisy J. Wright* (splendid fancy), *Royal Purple*, *Royal Blue*, *W. H. Woodgate* and a host of other good things. The *Violettas*, so well adapted for the rock garden, are well shown, this grower having raised most of the recent acquisitions. Some that appeal to us are *Estelle* (minute white), *Rock Blue*, *Rock Lemon*, *Rock Orange*, *Mollie*, *Purity*, *Violetta*, *Eileen*, *Queenie*, *Bluebird*, *Sweetness* and *Vestal*. These are a few of the better of these dainty little sweet-scented flowers.

Violas, chiefly of the exhibition kinds, are well shown by Messrs. W. Seagrave and Co., Sheffield. This firm invariably show well, and their blooms, being grown further North, appear to suffer less from the weather than those of their Southern rivals. A careful look through this and other *Viola* exhibits is proof conclusive that great strides have been made in the development of this subject in recent years.

Mr. William Arkwright, Sutton Scarsdale, Chesterfield, has an exhibit of especial interest to lovers of the Viola. This gentleman has been working on definite lines in order to give the world something new and distinct in the way of colour, &c. We believe he hopes to get a good Viola of a crimson or kindred tone of colour, and his exhibit goes to prove the care he is taking in the development of this interesting subject.

Violas, among other subjects, are shown by Messrs. Carter Page and Co., London Wall, E.C. The flowers are well grown and represent a number of the better kinds in general cultivation.

As usual, Mr. John Forbes, Hawick, makes a display at the entrance to the show grounds. Among other hardy flowers, he shows a good list of Violas in well-known and interesting varieties. There are good selfs, fancy and edged sorts, and all combine to add materially to the value of this grower's display.

TREES AND SHRUBS.

Situated immediately to the left on entering the grounds is seen an extensive group of Japanese Maples shown by Messrs. W. Fromow and Son, Sutton Court Nurseries, Chiswick. The foliage is varied both in form and colour. The bronze-tinted *Acer laciniatum purpureum*, *sanguineum* and *septemlobum purpureum* are greatly in evidence, also a fine basket of *Acer versicolor*, with small crimson and variegated leaves.

From the Hon. Vicary Gibbs, Aldenham House, Elstree (gardener, Mr. E. Beckett), comes a rare and interesting collection of new Chinese plants, including *Acer Henryi* and *Ailantus vilmoriniana*. Very few of the shrubs are flowering, although *Indigofera viciifolia* and one or two unnamed *Potentillas* are notable exceptions. This collection of little-known trees and shrubs makes a very imposing feature.

Mr. L. R. Russell, Richmond, is showing an interesting group of ornamental shrubs, with a Lily pool in the foreground. Among the shrubs will be noticed a great variety of standard and bush Ivies, Japanese Maples and the handsome *Dimorphanthus mandshuricus foliis argentea variegata*.

Judging by the large collections of clipped Yews and Boxes, it would seem that there is a revival of interest taken in the so-called topiarian art. The trees are shown clipped in all manner of fantastic, and in some instances grotesque, forms. Peacocks, balloons and spirals appear to be favoured designs. Clipped Yews and Boxes are shown by various firms, including Messrs. Cutbush, Highgate; Messrs. Piper of Bayswater; and Messrs. Cheal of Crawley.

Mr. G. Reuthe, Keston, has a group of rare shrubs, comprising *Rhododendrons*, *Crinodendrons*, *Celmisias* and a dwarf Beech from Antarctic regions.

A very choice collection of shrubs is shown by the Donard Nursery Company, Newcastle, County Down. The new forms of *Leptospermums*, *L. Boscawenii*, *L. Nichollii* and *L. Chapmannii*, form the chief features of the group. There is also an interesting collection of *Pittosporums*, including *eugenoides variegata*, while *Ozothamnus rosmarinifolius* is seen flowering with its accustomed freedom.

Messrs. John Waterer, Sons and Crisp, Limited, Bagshot, Surrey, are showing a variety of late *Rhododendrons*, also a grand display of *Kalmia latifolia* interspersed with standard Maples.

Messrs. Jackman, Woking, are showing Clematises in great variety. Some of the older varieties still hold their own, although there are delightful art shades among the newer sorts.

FRUIT AND VEGETABLES.

From Messrs. Ware, Feltham, comes a collection of pot fruit trees well laden with their luscious and highly coloured fruits, which look uncommonly tempting. Plums, Peaches, Nectarines and Figs are all included, there being a representative collection of each.

Messrs. Bucks, Tresco, Ipswich, once again demonstrate the wonderful fruiting qualities of their Tresco Tomato, which is undoubtedly prolific and one of the most interesting things in the show.

Messrs. Bunyard and Co., Maidstone, are showing fruit trees in pots, which reflect the highest credit upon the cultivation given them. Roses and herbaceous flowers are alike well shown by this well-known firm.

Pot fruit trees are shown by Messrs. J. Veitch and Sons, Chelsea, in the high standard of excellence that we have long learnt to associate with this firm. Peaches in standard fan-shaped trees, Plums as espalier and Apples as bush trees are all to be seen in the height of perfection and carrying heavy crops. Peaches Early Alfred, Peregrine, Hale's Early and Duke of York; Nectarines Early Rivers, Cardinal and Lord Napier; Plums Jefferson, Dennison's Superb, Oullin's Golden; Apples Lady Sudeley and James Grieve are chief among the varieties shown.

The Cherry trees in pots shown by Messrs. T. Rivers and Son, Sawbridgeworth, are worthy of special note by virtue of the heavy crops they carry. Black Tartarian, Frogmore Bigarreau and Bigarreau de Schreken are truly superb. Lady Sudeley Apple, handsomely coloured, is used with good effect in the foreground, while among the Peaches the crimson variety Peregrine is exceptionally fine.

The collection of vegetables shown by the Hon. Vicary Gibbs, Aldenham House, Elstree, reflects great credit upon Mr. E. Beckett, the able gardener. Backed by Globe Artichokes, Turnip-rooted Beet and Cauliflowers, there are exceptionally fine dishes of Peas Duke of Albany and Centenary (specially good), Beet Sutton's Globe, Carrots Favourite and New Red Intermediate, Vegetable Marrows Table Dainty, Moore's Cream and Perfection, Potatoes May Queen, King Edward and Gladiator, Tomatoes Perfection and Peach Blow.

Messrs. Laxton Brothers, Bedford, have a superb collection of Strawberries, all of large but even size. Among the pick of the varieties are Progress, The Bedford (very sweet and of Pineapple flavour), Reward, The Laxton and Givon's Late Prolific.

SUNDRIES.

The Chase Continuous Cloche Company, 11, Queen Victoria Street, E.C., are in full evidence, and if only a very small percentage of sunbeams are caught on this occasion, the temperature maintained by this system would be quite sufficient to cultivate even the tenderest tropical plants.

Visitors show a decided preference for Messrs. Castle's of Milbank, S.W., stand, where it is possible to rest and enjoy the ease and comfort provided by their most durable garden seats. Other suitable garden furniture of every description is on view.

Judging from the prevalence and devastations of the various insect pests in the garden during

the present year, there should be a great demand for insecticides of every description, and the stand displayed by Messrs. William Cooper and Nephews should prove of great assistance to amateurs visiting the show.

"Dryad" Cane Furniture suitable both for indoor and outdoor use is shown in great variety and in the most artistic and useful forms by the Dryad Works, St. Nicholas Street, Leicester.

The Folding Span Lights, which are arranged to show the utility of this invention as a means of raising early crops and protecting others, are shown to their best advantage by the Folding Span Light Company, Slough.

Spraying machines of the latest pattern and design which include all the improvements which modern science and practice can suggest, combined with garden syringes, sprinklers, pumps, &c., are prominently displayed by the Four Oaks Company, Sutton Coldfield, Birmingham.

The French Cloche Company, Caxton House Westminster, S.W., have a good selection of cloches, frames, and all other French garden requisites on view which are suitable for all gardens, from the smallest to the largest.

Messrs. Jeyes, Limited, Cannon Street, E.C., have also a selection of their well-known horticultural specialities on view, which have been proved most serviceable to all garden-lovers.

Messrs. Hartgen, 35, Noble Street, E.C., have a good selection of Holder sprayers on view, in various shapes and sizes, which can be adapted to all requirements for both large and small gardens.

Capturing the slug by means of the special slug trap designed by Mr. Vernon T. Hill, Mendip, offers great opportunities both to amateurs and others who suffer from the ravages of this pest.

Teakwood garden furniture, manufactured from battleships by Messrs. Hughes, Bolckow and Co., Limited, 10, Dover Street, W., and Blyth, is shown in various designs, including seats, tables, chairs, arches, &c.

A most interesting exhibit is that of Mr. H. Jones, Horscombe, Bath, who shows a good variety of designs in stone vases, balustrades and garden seats.

Messrs. Robinson Brothers, Limited, West Bromwich, have an ancient castle well fortified and equipped with weapons and ammunition which can be adapted by both amateur and professional horticulturists for the destruction of all insect and fungoid pests, and by the most dainty plant foods obtainable they are prepared to coax the best possible results even from plants which are most fastidious in taste.

To those who have an inclination to indulge in rock and flower gardening, Messrs. Thomson and Charman, 11, Adam Street, Adelphi, are prepared to render every possible assistance with plans and advice.

The falling off of horse traction and the increased number of motors has raised the question of less manure for the garden. To some this may be a serious one, but Messrs. Wakeley Brothers, Honduras Wharf, Bankside, S.E., are doing their level best to make up for the deficiency. Their patent Hop Manure is certainly the best substitute for stable manure at the present time, and is a most valuable plant food for both town and country.

* Owing to the demand on our space we are compelled to hold over until next week particulars of a number of exhibits at Holland House. For the same reason reports of the Sherborne Floral Fête and the Isle of Wight Rose Show are also deferred.

THE HELIANTHEMUMS OR SUN ROSES.

DURING June and July the various kinds of Helianthemums or Sun Roses are among the most beautiful plants in the rock garden, while they are also effective on dry banks and walls. Even outside the garden the common kind may often be found making very beautiful pictures, for it is wild in many parts of the country, and often forms, with short grass, the principal vegetation upon poor, thin soil overlying rocks on hill and mountain sides. In such places the rich golden flowers besprinkle the grass in much the same manner that the Buttercup does in moist meadows.

Under cultivation the common *H. vulgare* has undergone a considerable change, for not only does it appear as a taller and more compact plant than is usual in a state of Nature, but the colour of the flowers has changed to a remarkable extent; and whereas it is rare to find any other colour than the orthodox gold among wild plants, we find that under cultivation there are kinds with white, cream, pink, red, and copper coloured flowers. Some of these kinds are selected forms which have sported from the type, and others are hybrids between *H. vulgare* and closely allied British and Continental species. It is, however, easy to find how soon a selection of varieties may be procured if seeds are taken from a mixed collection and sown. Not only will there be a wide range of colour among the seedlings, but the strength of the plants will also show great variation. This also indicates how difficult it is to propagate and keep true even the most distinct forms from seeds; therefore cuttings must be relied upon not only for the increase of the garden hybrids and varieties, but also for closely allied species when the plants are growing in close proximity and the flowers are easily cross-fertilised by insects. Cuttings of short shoots taken during June or July, dibbled into pots of sandy soil and placed in a close frame, root quite well, and at the end of the first year form nice plants for permanent positions. They must, however, be kept in pots until they can be placed out permanently, for they transplant with difficulty. Moreover, small plants are preferable to large ones for positions where the soil is scarce, such as crevices between rocks in the rockery, or niches in loosely built walls.

An annual cutting over as soon as the flowers fade is attended by good results, for the untidy dead flower-stalks are thus removed and more room is made for young shoots. Helianthemums are often rather short-lived; therefore it is wise to destroy old plants which show signs of declining health, and commence again with good stock. Among the many kinds which may be procured,

the following species and varieties will be found desirable: *H. vulgare* and *H. glaucum* are closely allied plants, the latter differing from the former mainly in its greyish leaves; another plant which also has grey leaves, and is sometimes classed as a variety of *H. vulgare* and sometimes as a distinct species, being *H. croceum*. They hybridise very freely, and the many garden forms which are usually attributed to the common Sun Rose may with equal rights in many instances be classed with one or other of the other species. Good forms for general planting are album, with single white flowers, and album plenum, with double white blossoms; carminatum has red flowers and it also offers a double-flowered form; Fireball has bright red, semi-double flowers; cupreum

WHITE SUN ROSES ON A RETAINING WALL

has copper-coloured blossoms; while Magenta Queen has magenta blooms; Rose Queen, rose; roseum, rose; flore pleno, double yellow; venustum, scarlet; and rubens, orange-coloured flowers respectively.

H. polifolium is a distinct species, which is of looser habit and a taller plant than *H. vulgare*. Its leaves are greyish and rather narrow, while its flowers may be pink or white. *Rhodanthum*, a red-flowered plant, is sometimes claimed to be a variety of this.

H. alpestre and *H. vineale* are a couple of choice little plants, rather more tender than the commoner species. They should be given a sunny position on the rockery, where they will form pretty little tufts a few inches high and bear their bright yellow blossoms with great freedom.

H. umbellatum is a rather stiff, upright-habited bush from Southern Europe. It grows from 9 inches to 18 inches high and is recognised by its small, Rosemary-like leaves and upright racemes of white flowers. There is also a distinct group of Sun Roses composed of a few species, the best-known one of which is *H. formosum*. A native of Portugal, it forms a spreading bush 2 feet or more high, with greyish leaves and yellow flowers $1\frac{1}{2}$ inches across, which are peculiar by reason of the brownish blotch found at the base of each petal. It is quite hardy and an excellent kind to plant where it can be allowed plenty of room. Others of the same set and plants of rather similar habit are *H. alyssoides*, *H. halimifolium* and *H. ocyroides*. The first named has yellow, unblotched blossoms; while the other two have their golden flowers marked with brown. All four plants must be given a sunny position in order that the wood may become thoroughly ripened. They are sometimes mistaken for the allied genus *Cistus*, but are recognised as Helianthemums by the three-celled ovary.

CALCEOLARIA GOLDEN GLOW.

THE cultivation of the few known hardy Calceolarias has received an impetus since the production of the fine hybrid raised by Messrs. Veitch of Exeter called Golden Glow, and which is now fairly well known in the best gardens. It may be considered as generally hardy, and is one of the most ornamental flowers of its class in summer. One finds, however, that the species called *polyrhiza* is not too much cultivated, although by no means a rarity, and possessing a constitution of undoubted hardiness throughout at least the greater part of the British Isles. Its creeping growth renders it excellent for rapidly covering a good-sized space, where its neat leaves and quaint yellow flowers make a pleasing display.

It is not generally known that there are at least two forms of this Calceolaria; and as it is a plant which is widely distributed in its native home—

Chili—there are probably others yet to come under our notice. At present, however, we have two—one with considerably smaller flowers than the other, and also of lower stature and less vigorous in the growth of its leaves. As for their cultivation, these two forms of *C. polyrhiza* are very accommodating. Some recommend bog treatment, and they certainly thrive under such conditions, but they will also do well in a soil of a dry nature with plenty of stones among it, while I have never seen the larger form finer than in ordinary soil in a nursery border. This fine hardy Calceolaria is a gem for the rock garden, especially in places where it can be allowed to spread into generous masses, where its golden flowers will look so well in the light of a midsummer day

Dumfries.

S. ARNOTT.

THE BEST CACTI FOR THE GREENHOUSE.

AS stated by a writer in a recent number of THE GARDEN, it is a matter for surprise that one does not see more frequent mention of the different members of the Cacti family, as they have so many claims to recognition. The quaint and uncommon appearance of many of them constitutes one noteworthy feature; then, we have a great many whose ribs and spines are disposed with quite mathematical precision. Next, the blossoms of many of them are remarkably showy; and lastly, being so accustomed in a state of Nature to long periods of drought, one may take one's summer holiday without any danger of these succulents suffering from drought in the

care that they are well drained. A suitable compost will consist mainly of loam, lightened by a little broken brick rubble and sand. They may be watered moderately during the summer, provided always that the drainage is perfect; but in the winter very little water will be required.

Flowering Cacti.—A vast number may be included under this head, the blossoms of so many of them being very remarkable; but the term is more generally applied to the different forms of *Cereus* and *Phyllocacti*, whose blossoms are in many cases really gorgeous. These are more of a shrub-like nature, for the flattened branches attain a considerable size. It has often been a matter of surprise to me that the different *Phyllocacti* (the garden forms of which are almost innumerable) should not be more grown, for, though it may be urged against them that the blossoms do not long remain, yet in the case of

while the large creamy white blossoms of *Cooperi* afford a pleasing variety in colour.

Complaints are by no means infrequent that these *Phyllocacti* do not flower so freely as they ought to do, and when this is the case it is often caused by not exposing the plants sufficiently to the full sunshine. Of course, they may be shaded when in bloom, as the flowers then last longer; but at other times they should have the benefit of all the sunshine available. Should the plants need repotting, it is best carried out directly the blossoms are over. A mixture of two-thirds loam to one-third leaf-mould, brick rubble and sand will suit all the *Phyllocacti*. They are readily struck from portions of the branches taken during the early summer months, inserted into pots of sandy soil and placed on a sunny shelf. Care must be taken not to overwater.

Those two very nearly allied forms of *Epiphyllum*, namely, *E. Gærtneri* and *E. makoyanum*, that bloom in the spring and early summer months, claim recognition. They differ from the well-known *E. truncatum* both in their season of blooming and in the shape of their red blossoms, which are regular in appearance and suggest a small kind of *Cereus*. The style of growth is just like that of *E. truncatum*.

Many species of *Cereus* take up a considerable amount of room, but one species—*Cereus flagelliformis*, known popularly as the Rat's-tail Cactus—is a delightful basket plant. When suspended, the long, round shoots hang down for a considerable distance, and in the summer, when its bright rose-coloured blossoms are at their best, it forms a delightful feature.

The Night-flowering Cacti, of which *Cereus grandiflorus* is one of the best known, need a large structure and a fair amount of heat for their successful culture.

Of smaller-growing Cacti remarkable for their quaint shapes, peculiarly arranged spines and pretty flowers may be mentioned the various forms of *Echinocactus*, *Echinocereus*, *Echinopsis* and *Mammillaria*. Apart from the Cacti proper, various other succulents, such as some members of the genus

Agave, Aloe, Crassula, Echeveria, Gasteria, Haworthia and Mesembryanthemum, are well worthy of association with them. H. P.

PÆONIA LOBATA, A BEAUTIFUL SPECIES WITH TULIP-SHAPED FLOWERS.

meantime. It is, I know full well, often a source of worry to the owners of greenhouses to arrange for the plants being attended to during their absence from home, and the arrangements made do not always turn out satisfactory. With plants so indifferent to drought as cactaceous plants in general, the results are very different. Another purpose to which they may be put is for growing in a sunny window, under which conditions they are just at home.

Miniature Cacti.—These are a source of interest to many, and, as quite a representative collection may be kept in a limited space, a considerable number may be grown in a window. As sold the plants are in small ornamental pots, and they will keep in health therein for a very long time without being disturbed at the roots. In order to grow them on, however, they will in time need to be shifted into larger pots, taking

good healthy examples a succession is kept up for some time, and withal the plants are of easy culture. Cacti of this class do not withstand drought like those of a more globular shape; indeed, during the growing season the plants require to be moderately watered. The flowers of many of these *Phyllocacti* are quite startling in their tones of colour and the contrasts which occur in the same bloom. In some flowers the main portion of the bloom is of an orange, orange salmon or scarlet shade, shot in the centre with vivid tints of violet, blue or purple. These features, which cause a flower to appear of a different colour, according to the standpoint from which it is viewed, are in some cases quite startling. There are also many other coloured varieties, some of the pinks being very pleasing. Quite a small pink-flowered kind, whose blossoms are borne in great profusion, is *Phyllocactus phyllanthoides* German Empress,

So much attention has been paid in recent years to garden varieties of the Pæony that there is a tendency to overlook this beautiful species. *Pæonia lobata* is a charming plant with glorious coral pink flowers and clusters of golden anthers. The flowers are Tulip-shaped, and distinct from garden varieties in both colour and form. It has this year been admirably shown at Vincent Square by Mr. James Box of Hayward's Heath, who gained for it a certificate of merit from the National Hardy Plant Society. It is not a new plant, although seldom seen, and it is not every year that it flowers with the freedom experienced this season.

PÆONIA LOBATA.

GARDENING FOR BEGINNERS.

HOW TO BUD ROSES.

1.—A BUD REMOVED AND PREPARED FOR INSERTION.

wichuraiana type stocks 6 feet to 10 feet high are most useful when they can be procured. The stocks should be cut off at the required height previous to planting, which should be done before Christmas. In spring a goodly number of shoots may be expected to push out from the Briar stems. About four of those nearest the top should be retained, the remainder being rubbed off with the thumb and finger as soon as they show. A sharp knife is a necessity for budding, and plenty of raffia, cut into lengths of 12 inches to 15 inches, should be kept close at hand, fastened to the waist. The best buds, as a rule, are those on shoots which are flowering or have just recently flowered. Such a shoot is shown in Fig. 1. Select plump buds which show no signs of growing. Cut off the leaves as illustrated, leaving about an inch of the leaf-stalk. The next operation is to slice off the bud, starting with the knife half an inch above the bud. Make a downward cut and finish off half an inch below the bud. In Fig. 1 a bud is shown removed ready for insertion, with the cut surface exposed on the shoot from which it has been removed. Remove carefully with the point of the knife the small piece of wood at the back of the bud, so that only the bud and a shell of bark remain.

Preparing the Stocks.—Should dry weather prevail, ample water ought to be given the stocks some days before the budding operations are to commence; this will make the bark run much easier. To commence on the stock, cut away

2.—TYING IN THE BUD ON A STANDARD BRIAR STOCK.

OF the several methods employed in the propagation of the Rose, budding is the most important and extensively practised. Outdoors the best time to bud Roses is the second half of July and during August. While many amateur Rose-growers prefer to purchase vigorous young plants from a nursery, there are others who take a delight in propagating some at least of their own Rose trees.

There are several kinds of "stocks" employed for budding—the Dog Rose (*Rosa canina*) of our hedgerows in three forms, the standard, seedling Briar, and Briar cuttings. The Manetti stock, which was originally obtained from Italy, is propagated by cuttings; so also is the De la Grifferrae stock. The Japanese *Rosa rugosa* is also used both as a standard and dwarf stock, being readily raised from seeds and cuttings.

Standard Roses.—The standard Rose stocks are mostly obtained from the hedgerows in the autumn and early winter. Planted in the garden, they will be ready to bud towards the end of the following summer. The height of the standard varies according to the size and strength of the Briars and the requirements of the grower. They, as a rule, vary from 2 feet (half-standards) to 4 feet in height for Hybrid Perpetuals and Hybrid Teas, while for the lovely weeping standards of the

3.—A STANDARD ROSE TEN MONTHS AFTER BUDDING

all thorns near where the bud is to be inserted. This should be at the base or as near the base of the young shoot as convenient. One and a half inches to 2 inches from the base make a cross-cut through the bark about half an inch long, then a longitudinal cut from the cross-cut 1 inch long in the direction of the base of the shoot. Next, take one of the prepared buds, carefully lift the bark at the cross-cut, and slide in the bud, holding it by the piece of leaf-stalk. The bud should now be tied in firmly with raffia, as illustrated in Fig. 2. If there are three or four suitable shoots, they should be budded, as there is always the possibility of failure, especially if the operator is inexperienced, while, if four buds take, it will be quite easy to remove the weaker. In about four weeks examine the raffia, when, if the bud has taken, the raffia should be loosened and tied more loosely. Some controversy exists over the right time to shorten the growths which are budded. A section of growers cut off the ends of the shoots when preparing the wood for budding, but experience points to it being better to defer all the cutting until late autumn, say, about November, the Briars then being cut back to within 3 inches or a little more of the bud. Having been successful with the budding, the most important matter is to tie the young growths securely to thin stakes. Fig. 3 depicts the top of a standard Briar photographed at the end of May, ten months from budding. O. A.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Winter Tomatoes.—A sowing of some free-setting variety should be made at once in order to secure a supply of ripe Tomatoes in the winter. Sow the seeds thinly in pots or pans and place in gentle heat until the young plants are well through the surface, after which they should be raised to within a few inches of the roof glass, so that they may not become drawn. Pot into 3-inch pots as soon as large enough, and again into 6-inch pots as soon as ready. When the final potting takes place, the soil may consist of two-thirds turfy loam and the remainder of leaf-soil with a good sprinkling of bone-meal.

Early Vines.—Now that the Grapes have been cut, the Vines should be syringed daily during hot weather. The lateral growth may be allowed to run, but not to become overcrowded. Examine the border, and, if necessary, give a good soaking of liquid manure from the farmyard.

Peach Trees.—Early Peach trees from which the fruits have been gathered should be carefully thinned out. Remove all wood which is not required for next season's crop. If this work is carefully accomplished now, the wood which is left will receive the full benefit of the sun to prepare it for another year, and winter pruning will be a very simple matter. Keep the shoots tied into position, and syringe freely during the remainder of the season to keep the trees quite free from insects. If the borders are well drained, a liberal supply of water should be given at the roots, previous to which a sprinkling of artificial manure may be applied with advantage.

Plants Under Glass.

Malmaison Carnations.—Now is the time to propagate these favourite flowers by layering. The best method is to set a cold pit apart for the purpose. Let the pit be filled to within 15 inches of the glass with good sandy soil, and select clean, healthy plants from which to propagate the future stock. These old plants should be carefully turned out of the pots and planted in the new soil, spreading the growths evenly over the surface, so that when the work is finished the pit may be full of clean, healthy shoots. Use a very sharp knife and cut through a joint on the under side of the shoot. Cover with sandy soil and peg carefully down, making the soil moderately firm. Keep the pit closed for ten days and protect from sun. The foliage should be damped frequently with clear soft water. When growth commences, ventilate the pit to keep the young plants from becoming drawn.

Mignonette.—A sowing of some good variety for pot culture may be made now to furnish plants for late autumn flowering. If sown in 6-inch pots and placed in a cold frame until the seedlings are ready to thin, they will make useful plants by the beginning of November. Five or six plants will be sufficient for each pot.

Herbaceous Calceolarias may be sown now and placed in a cold frame or under a hand-light behind a north wall. The soil should be thoroughly moistened before the seeds are sown, and only a light covering of the seeds is necessary.

The Flower Garden.

Hollyhocks.—The plants will benefit by frequent waterings of liquid manure. Old plants with several spikes should be secured to a central stake, or the wind may soon ruin them. If dry weather sets in, a mulching of some kind should be placed over the roots, horse-manure for preference.

Lilies which are throwing up their flower-stems should also be supported with stakes, and water must be freely given for the remainder of the season.

Flower-Beds.—The plants are making rapid progress, and a weekly inspection of them will be necessary in order to keep them within bounds. This applies to carpet bedding plants more particularly, as if left for a longer period they present an over-trimmed appearance when the work has been finished. Keep the grass trimmed round the edges of the beds, and pass the lawn-mower over the grass at intervals of a few days.

The Rock Garden.

Early Flowering Plants.—Many of these will have formed seed-pods, and these should be

secured before the seeds drop. Seeds which are to be sown in spring may be placed in small paper bags and kept in a dry room until the time arrives for sowing.

Primulas, many of which are excellent subjects for sunny positions in the rock garden, should be planted well above the level of the surrounding soil, as they are liable to suffer from damp during the winter. Primula seeds should be sown directly they are ripe. Sow thinly in pans of sandy soil, and place in a cold frame until the seeds germinate. Pot into small pots as soon as large enough and protect from strong sun. Established plants may be divested of all decaying foliage, and the soil lightly stirred between the plants previous to top-dressing with light, sandy soil.

The Hardy Fruit Garden.

Strawberries.—No time should be lost in securing a sufficient number of healthy layers to make the early plantation for next season. Royal Sovereign is still one of the very best Strawberries for early or midseason supplies, and if healthy layers are placed in small pots now, they should be ready for planting about the middle of August. The border for this purpose should be trenched 2 feet deep, and a dressing of decayed farmyard manure mixed with the soil as the work proceeds. When the soil has become settled and the plants are ready, they may be carefully planted in rows 2 feet apart and 15 inches from plant to plant in the rows. Make firm and see that they receive sufficient moisture at the roots.

Peaches and Nectarines.—The final thinning of the fruits should take place at once. Trees in this district are carrying a heavy crop, and unless they receive attention at once, the quality of the crop will suffer in consequence.

The Kitchen Garden.

Lettuce.—A sowing of Lettuce seed may be made at intervals of ten days from now to the end of August. The situation should be shaded during the warmest part of the day. A border facing east will be a suitable place for them.

Endive may be sown now for use during the autumn, and a fortnight later for early winter supplies.

Celery.—The maincrop Celery should be planted without delay, watering the plants thoroughly as soon as they are placed in position.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Shallots.—In many cases these will have completed their growth and be ready for lifting; this, of course, must be determined by their appearance. Those that are ready should be pulled up and placed in a sunny position to ripen, turning them frequently so that every part will be exposed to the sun. Should, however, the weather be wet, they had better be put under glass in a cold frame.

Winter Onions.—These ought now to be ready for harvesting, and, should the weather be fine, no time must be lost in taking them up. It will scarcely be necessary to string these up as is done in the autumn, but at the same time they should be spread out in an open position, well exposed to the sun.

Tomatoes.—Those that were planted out some time ago against a south wall will now be making rapid growth, and, as the idea should be to ripen the fruit as early as possible, the plants ought to be restricted to one stem and have the point pinched out when a sufficient number of fruits have set. Should a supply of water not be at hand, the plants had better have a mulch of farmyard manure, which will assist the fruit to swell and preserve the moisture in the soil.

The Flower Garden.

Carnations.—Many of the earlier-flowering varieties are now coming into flower, and it is advisable to reduce the number of buds, particularly the larger-flowered sorts. Varieties of the King Arthur and Duchess of Rothesay type can be more severely dealt with, while the smaller-flowered sorts had better be allowed to grow

naturally. Those plants that had the flower-spikes removed to allow the plant to make grass for layering will soon be ready, and no time should be lost in getting this work done. It is, however, too early to layer the main batch.

Violets.—Runners must be removed as they appear, so that all the energies of the plant may go to building up the crown. A dusting of soot from time to time will greatly assist in keeping down red spider, and if this is applied while the foliage is damp it will be more effectual.

Thinning Annuals.—It will be as well to go over the various annuals and give them a final thinning. These thinnings, I find, make a grand display later in the season if planted in bold clumps or used for filling up vacant spots in the herbaceous borders. Previous to planting, dip the roots in a prepared puddle, and supply them with water until they take a hold.

Plants Under Glass.

Hydrangeas.—The present is a suitable time to secure cuttings of this useful greenhouse plant. If space permitted, it would be as well to place the cuttings in the propagating-pit to encourage quick rooting. Where specimens are required, pot on the strongest of the young plants now passing out of flower; these should be cut back and brought on slowly.

Fibrous-rooted Begonias.—All this type will now require potting on—at least, as soon as the roots appear at the sides of the pots. After potting, keep them in a fairly hot house, and pick off the flowers as they appear. Many recommend pinching the points out of the young plants of Gloire de Lorraine; this, however, I think, is a mistake, as the plants seem to make far finer specimens if allowed to grow naturally.

Mignonette in Pots.—In the colder districts Mignonette might be sown in pots now to flower in the early spring. To ensure that the young plants do not receive a check, it will be as well to sow in small pots, two or three seeds in each, and afterwards reduce the seedlings to one. It must, however, be understood that Mignonette will not stand coddling in any shape or form.

The Hardy Fruit Garden.

Wall Trees.—All wall trees will now be greatly benefited by liberal supplies of water at the roots, especially those on walls that have a projecting coping, as on such walls the trees are practically deprived of any moisture that may be falling. Where it is at all possible, the trees should be syringed late in the afternoon on fine days; this will be found to be very refreshing, and also tend to keep the foliage free from red spider. If summer pruning has not been commenced, no time should be lost in seeing to this very necessary operation.

Loganberries.—At the present moment these are throwing up a mass of young growths, which, if not thinned out, will seriously interfere with the swelling of the fruit and the proper ripening of the canes intended for next year's crop. Select a few of the strongest canes and tie them up loosely to the wires, and the remaining shoots should be cut clean away. Afterwards give the ground a good dressing of farmyard manure.

Fruits Under Glass.

Strawberries.—To secure well-ripened crowns for early forcing in the spring, a start should at once be made in securing suitable runners, and these ought to be taken from young fruiting plants. Place these in 3-inch pots filled with good loam, and stand them closely together to facilitate the work of watering. On no account allow the young plants to become dry at the roots, and pot them into their fruiting pots before they root through into the ground.

Late Vines.—The thinning of Grapes intended to be kept well into the spring should be carefully attended to; the centre of the bunch especially should be looked over several times and thinned out, as it is here that the Grapes suffer most from damping. Keep all laterals well pinched; at the same time allow a sufficient covering of the foliage to protect the bunches. As Lady Downe's is very subject to scalding, great care must be exercised in ventilating that house, particularly in the morning.

JOHN HIGHGATE.

Hopetoun Gardens, South Queensferry, N.B.

AFFINITIES IN RELATION TO POLLINATION OF FRUIT TREES.

ONE often hears of a tree flowering most profusely that seldom bears a crop of fruit, and, on going deeper into the subject, it is apparent that the tree is self-sterile. Not far from Hereford a large Pear tree flowered well every season, but had no fruit on it for over six years. When, a few years ago, I advised the owner to tie a rabbit's skin to a pole, brushing it lightly over another variety of Pear, then gently touching the blooms of this fruitless tree, he carried out my instructions, and during the past two seasons, and owing to this process, he has obtained a bountiful crop, so prolific that it has induced a fruiterer from Hereford to run a dray sixteen miles to secure the fruit and pay the best price for it. Here one can see at a glance the value of planting an affinity near this tree, as it is evident this variety requires pollination distinctive. The varieties on observation for use in setting are Fertility, Comte de Lamy, Josephine de Malines, Glou Morceau and Louise Bonne de Jersey, these varieties being potent factors, and appear to pollinate the several other varieties surrounding them.

The Apple family is also, in most varieties, self-sterile, and in many orchards, especially where one variety has been planted in a block, pronounced sterile tendencies are shown. Therefore, to avoid this, one should plant those varieties we know on observation to be affinities. Recently I saw a glaring case of varieties being in proximity which proved a pollinator perfect, viz., Cox's Orange Pippin and Peasgood's Nonsuch, surrounded by several Warner's King, and in each case there was a splendid set of fruit; the same two varieties in the same orchard, but a considerable distance from the first-named, surrounded by Cox's Pomona, had scarcely a fruit on them. This proves conclusively that the variety Warner's King is the potent factor in the production. Within a few miles of Hereford there are some fine specimens of Blenheim Orange Apple trees, probably fifty years old, and until fourteen years ago a good crop was given, but latterly the return has been very small, and on information I found that a fine old specimen Crab (*Pyrus Malus*) had been uprooted by the elements, and since then the crop had always been scarce. Here we see the value of an indigenous variety to assist pollination, and a real asset, to my thinking, as no doubt the loss of the Crab Apple proved the reason of the failure; and one will have noticed that wherever the Crab Apple is in proximity to any variety of the Apple, so sure is there to be a crop.

Potent factors on observation appear to be Warner's King, Bramley's Seedling, Lord Derby, Worcester Pearmain and Bismarck; these undoubtedly would prove satisfactory if intermixed with every good variety in the proportion of about one to eight. Plums are exactly in the same category. In many orchards or plantations one will find sterile varieties, and the remedy is to graft or intermix with affinities. On close study one will find these in Monarch, Czar, Victoria and Prolific. These are sure fertilisers for most of the remaining varieties, but I advise, in the arrangement of the plantation, to plant in the proportion of one to six. I have several times advised planting Prolific near the varieties of the Gage family,

and in most cases have to record an unqualified success. In any case, never plant a block or quarter of any one variety unless intermingled with some of the sorts previously named, and it would also be wise never to plant any one sort, even if known to be self-fertile, as each and all are much more profitable if pollinated distinctively.

Now, a word as to the remedy in making these old trees fruitful in some of the old orchards. My advice is to head two branches on every fourth tree, one on the west, the other on the east side of the tree, and graft these with Warner's King and Bramley's Seedling—these two varieties have pronounced fertile properties—unless there are vacancies to plant young stocks of these varieties. But the grafting process is the quickest way to obtain maturity.

The pollen grains, no doubt, are carried, in a great measure, by the breezes, although I am convinced that insects have been in a large measure a great factor in bringing pollination to a successful issue. At the same time, I know of trees in orchards five to six miles from the nearest beehive, and yet an abundant crop has been taken from these trees in most seasons, and I contend it would be impossible in a mature orchard, say of ten acres, and trees in age varying from fifty to eighty years, for any insect to visit the entire crop of flowers, or even a small proportion of them, especially as experienced this season. Therefore, the zephyrs have the primary work to do, and it is a matter of serious consideration and interest to cultivators of hardy fruit to study these simple matters daily, and employ methods more encouraging than hitherto, as, commercially, the prospects are good and the demand great. GEORGE J. LOVELOCK.

THE EDITOR'S TABLE.

Buddleia Colvillei from Exeter.—Messrs. R. Veitch and Sons of the Royal Nurseries, Exeter, send sprays of this handsome shrub, also photographs showing the size of the specimen growing in their nurseries. Unfortunately, these were not suitable for reproduction. The flowers of this *Buddleia* are a sort of brick red in colour, and are produced in large, somewhat loose, pendulous panicles. It is a pity that their scent is not quite what we can term pleasing. Messrs. Veitch write as follows: "We are sending you herewith sprays of *Buddleia Colvillei*. The tree, of which we enclose photographs, was planted out in 1901, and now stands 16 feet in height, with a spread of 21 feet and carrying about three hundred trusses of its large pink blooms. It has never shown the slightest injury by frost, though one season we registered 21°."

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PÆONIES NOT FLOWERING (W. D.).—The most probable cause of the non-flowering of the Pæonies is the dry spring of 1913, which, militating against good growth, also prevented the formation of flowering crowns. All you can do now is to supply the plants liberally with water and liquid manure, though it would have been better had it been started two months ago. As the plants are healthy, they appear to be lacking in vigour.

TREATMENT FOR AQUATICS (Sagittaria).—You had better allow the water to trickle continuously into your Nymphaea tubs, or at any rate for several hours each day. Goldfish may be placed in the tubs if you like, but they will not be likely to keep the water clean. A constant supply of fresh water is what is most needed. The tubs should be cleaned out and the Water Lilies planted in new soil each year. March is a good time for the work. Be careful to remove decaying leaves and flowers regularly through the summer.

A SEEDLING VIOLA (R. W. D.).—The colour of your seedling *Viola* is very charming, and until quite recently there were no varieties in commerce equal to its beautiful light blue tone of colour. Two years ago, however, a rayless variety named W. H. Woodgate was introduced, and the blue colouring in this variety is practically identical with that of your seedling. The lines radiating from the centre of the bloom of your variety, in our opinion, detract from its value, and that is why we have a distinct preference for the variety we have named.

A RHODODENDRON FOR THE ROCK GARDEN (Teregram).—The specimen sent for identification is *Rhododendron indicum* var. *balsaminiflora*. It is a well-marked variety of the popular Indian Azalea, or Indian *Rhododendron* as it is correctly called, *R. indicum*, and has long been in cultivation. Both dwarfier and hardier than the type, it is an excellent plant for the rock garden or border in the warmer parts of the country, and even thrives fairly well in some parts of the Midlands. Mature plants are often no more than 12 inches high, but very bushy. As a rule, it blossoms freely from the time when it is but an inch or 2 inches high. Cuttings of half-ripe shoots root well in sandy peat in a close frame during summer, and good plants may be purchased from any of the nurserymen who make a speciality of hardy plants.

A SELECTION OF DAHLIAS AND VIOLAS (H. T.).—You will find the following Cactus and single Dahlias a useful lot for cutting: Cactus—Charles Woodbridge, Countess of Lonsdale, Lord Roberts, Loyalty, Lucius, Magnificent, Mrs. C. Gaze, Red Rover, Starfish, Up-to-date, William Jowett and Zephyr. Singles—Alice Seale, Beauty, Folly, Alice, Jeannette, Northern Star, Polly Eccles, Phyllis, Victoria, Miss Roberts, Mrs. Cannell and Mrs. Watson. Six showy and free-flowering Violas are Countess of Hopetoun, Countess of Kintore, White Duchess, Archie Grant, Primrose Dame and J. B. Riding. Six good Pansies will be found in Agnes Kay, Dr. Campbell, Leviathan, George Stewart, Lord Roberts and Miss Neil. It is not, however, worth while purchasing named varieties of Pansies unless they are required for a special purpose, as seedlings are now quite as good. Bone-meal, basic slag and kainit are suitable manures for your lawns and meadows.

VARIOUS QUESTIONS (Reader).—It is not usual for Soldanellas to flower a second time, and too frequently they refuse to flower at all. This year we have seen more than one instance of later flowers, though in all probability the crowns now flowering did not do so earlier in the year. You appear to have been very fortunate with your Sweet Peas, and the plants generally are doing well this season, particularly so those sown in September last on chalky loams and in good holding soils. The result, in some measure, may also be due to the conditions under which last year the seeds were grown, a bad or good growing and ripening season not unnaturally affecting the crops, as also the subsequent season's growth and development. Erythras are, as you say, deserving of more extended cultivation, though they are grown and appreciated in many gardens. You are also fortunate with your Tomatoes, as in some districts these have suffered from the late spring frosts.

AUBRIETIAS NOT FLOWERING (E. V. S.).—We might have formed a more correct opinion as to the failure had you given some particulars as to the position and cultivation generally. In the absence of these we can only presume that the plants are in too rich a soil, or in the shade with considerable moisture at hand. These plants are most prodigal in their flowering when growing in comparatively poor soil in full sun, as, e.g., ledges of rock or as edgings to pathways and like places. With these, firm planting is an important factor. If your plants are not in a fully exposed place, you should transfer them to such an one without delay and give them a poor soil into which old mortar, gravel, sand or broken sandstone enters freely. By pruning now to within 3 inches of the soil, the plants would break away again in a month, and may be replanted then if you can give the necessary attention to watering and shading till they are re-established. We are complying with your further request.

PROPAGATION OF DIANTHUS AND ONOSMA (A. O. S.).—The only practical method is by heel cuttings severed with a slight downward pull from the parent plant and inserted without more ado. Layering is impracticable, and, indeed, impossible of good results in the case of the *Onosma*, and cuttings made to a supposed "joint" have no possibility of rooting, owing to the peculiarity of the growth. On the other hand, heel cuttings in sandy soil in a cold frame in June will root readily. Hence your enquiry is in the nick of time. The *Dianthus* may be rooted from June to September by employing the same type of cutting in like circumstances. In this case a greater number of suitable cuttings will be produced if you suppress the flowering by the removal of the centre of the larger growths and wait for the coming of the lateral branches at their bases. Secure these cuttings when 2 inches or so in length. Do not use the knife to the *Onosma* in any circumstances. It is also bad for the *Dianthus*.

TREES AND SHRUBS.

CLEMATIS DISEASED (T. W.).—From what you say about your Clematis we imagine that it is suffering from a disease common to the garden forms of the genus. This disease causes apparently healthy plants to behave in the manner you describe, and they usually die within a few days. The best plan is to plant them where the sun will not strike the lower part of the stem, for although the upper branches like sun, the lower parts are easily injured by fierce sun-heat. Nothing can be done to improve your plant, we are afraid. Your Sweet Peas and Green Peas are apparently attacked by some disease, but we cannot say what disease or advise about them without seeing the plants.

SHRUBS AND CATERPILLARS (A. G. S.).—Your Clematis has evidently been attacked by caterpillars or some other insect pest, the damage being done and the caterpillars turned into chrysalides before you noticed the injury. Your newly planted shrubs are evidently suffering from drought; they should be kept well watered during dry weather until properly established. You may reduce the shoots by 9 inches or 12 inches at the present time, as the plants appear to be suffering from insufficient root action, though it is not absolutely necessary to prune such shrubs as you mention the first year after they are planted. A surface-dressing or mulch of well-rotted manure will do good by keeping the soil cool and moist.

STAPHYLEA BEARING DIFFERENT KINDS OF FLOWERS (E. W. N.).—The specimen sent for determination is not the typical *Staphylea colchica*. It is probably *S. Coulombieri*, which is a hybrid between *S. colchica* and *S. pinnata*. The smaller flowers are typical of *S. pinnata*, and the others of *S. colchica*. Although it is not usual for the hybrid to produce two kinds of flowers, a branch or two may have sported, or your plant of *S. colchica* may have been grafted upon *S. pinnata*, branches of the latter having grown from the stock and the bush bearing typical branches of two species. Had the two kinds of flowers appeared before, we should have imagined it to have been a grafted plant.

PRUNING SHRUBS (E. C.).—Two distinct kinds of shrubs are known by the name of *Syringa*. As a generic name it is applied to the Lilacs, and as a common name it is used in connection with the Philadelphuses or Mock Oranges. We presume that you refer to the latter shrubs, and if that is the case, you may shorten the long branches as soon as the flowers are over. As a rule, it is only usual to thin out the branches of the taller-growing kinds every three or four years; but those of low growth, the Lemoinei section, are improved by having the flowering wood cut away each year, leaving as many strong young shoots as possible. Should you refer to the Lilac, the long shoots may be shortened when the flowers are over, and the weak growths from the side of the plant should be removed. It is also wise to keep the base of the plant free from suckers.

TAKING CUTTINGS OF SHRUBS (Harry O.).—It is unlikely that you will be able to strike any of the plants you mention, except *Ceanothus*, out of doors or in your greenhouse, unless you possess a frame which can be kept close and shaded. You may then be able to root branch cuttings of *Pittosporums*, *Ceanothus* and *Choisya ternata* at the present time, and *Romneya Coulteri* in spring, by taking cuttings of the roots as thick as a lead pencil and 3 inches to 4 inches long, and inserting the pieces singly in small pots of sandy soil. You will probably do better by layering the lower branches of your shrubs in the borders where they stand. When rooted, the branches can be removed and treated as separate plants. If you order the *Viola* from any of the leading nurserymen who advertise

in THE GARDEN, you will be able to secure the number of plants you desire. It is not unusual for the Bottle-Brush Tree to bloom out of doors in the Isle of Wight.

AUSTRIAN PINE SHOOTS WILTING (J. S.).—The wilting of the Austrian Pine shoots appears to have been due to the presence of larvae of the Pine shoot moth (*Tortrix* or *Retinia buoliana*), but there were no larvae in the sections sent. Probably by a careful examination of the plants you will find the insect. All that can be done to prevent the spread of the disease is to remove and burn the affected shoots at once.

HYDRANGEA PANICULATA (H. T.).—This shrub does not thrive as a pot plant for any considerable length of time, and as it is quite hardy, you would do well to plant it out of doors at once in rich, loamy soil. The branches should be pruned well back each year. As a rule, the shoots formed the previous year are cut back to within two or three buds of the base in February. The flowers being borne on the current year's wood, all pruning may be accomplished while the plant is at rest. When the young shoots are about three inches long, thin them out, leaving but one or two of the stronger ones to each of the previous year's shoots. As it is a rank feeding plant, provide a surface-dressing of well-decayed manure each year after it has become established, and, after the buds appear, their development may be assisted by an occasional application of manure-water. It is only usual to flower plants once in pots, and then plant them out.

THE GREENHOUSE.

INJURY TO PELARGONIUMS (Druid).—The Pelargoniums are attacked by a fungus near the root, leading to the blackening of the stem. We advise you not to use old potting soil in future for potting on the plants—not, at least, until it has been stacked for some time, for it often harbours plant pests.

BRUGMANSIA LEAF ATTACKED BY RED SPIDER (G. Y.).—The Brugmansia is attacked by red spider, a pest that is probably attacking the *Salvia* too. The latter is too much dried up to enable us to be certain. You have probably permitted the house to become too dry, and so encouraged the red spider. A moist, buoyant atmosphere assists in keeping this pest in check, while a dry one encourages it. Fumigate on two occasions within four or five days.

TREATMENT OF ZONAL PELARGONIUMS (Zonals).—Zonal Pelargoniums such as those indicated by you, and which are now in 4½-inch pots, should, if potted into 6-inch pots, make good flowering plants for the spring and following summer. The main object should be to encourage a sturdy habit of growth, and in order to induce this the plants must have all the air possible; indeed, they may, during the summer, be stood on a firm bottom out of doors. The soil best adapted for Zonal Pelargoniums is good fibrous loam, lightened with a little leaf-mould or well-decayed manure and sand. The cuttings referred to by you should make a good succession to the larger plants.

CARNATION LEAVES DISEASED (F. C. C.).—The Carnation leaves sent are very badly infested with that troublesome disease known as Carnation spot. It is generally supposed to be brought on by damp, cold climatic conditions, from which one would be inclined to think that your house has been kept too close, and, consequently, the atmosphere is too moist for the welfare of the plants. If the ventilation of the house needs attention, this should be seen to at once, for a buoyant atmosphere with plenty of light is very essential to the successful culture of the Carnation. At present we should advise you to pick off all the leaves that are badly infested and syringe the plants with Veltha Emulsion according to the directions supplied with it.

PLANT FOR NAME AND TREATMENT (X. Y. Z.).—The leaf of the plant sent for determination is a species of *Eucharis*, apparently *E. grandiflora*, although the leaf is not the full size for that species. The plant should be grown in a tropical house with a minimum summer temperature of 60° to 65°, with a winter temperature 5° lower. It must never be allowed to become dry, as the leaves are evergreen in character. Frequent repotting must be avoided, as the bulbs dislike root disturbance; but manure-water may be given with advantage while young leaves are being formed. Keep the atmosphere of the house moist and syringe the leaves well twice a day, taking care to get the water beneath as well as on the upper surface. Do not allow insect pests to obtain a footing, and encourage growth by every possible means. As the bulbs acquire strength, flowers will be borne freely.

GREENHOUSE FLOWERS IN WINTER (A. M. G. B.).—There are a great many subjects that will flower during the winter in a greenhouse maintained at a temperature of 50° to 55°. Such plants will include Carnations, Zonal Pelargoniums, *Primula sinensis* in variety, *P. obconica* in various forms, *P. malacoides*, *P. kewensis*, *Cyclamens*, *Bouvardias*, *Cinerarias*, *Salvias* of sorts, the earlier-flowered *Azaleas* (particularly *Deutsche Perle*) and *Arum Lilies*. At the same time we wish to point out that it is too late now to commence the culture of any of these plants with the anticipation of their flowering in a satisfactory manner this winter. Most of them, however, can be obtained as small plants from many of the advertisers in THE GARDEN, and all that is needed is to shift them into larger pots and place them under conditions favourable to growth. If Roman Hyacinths are potted towards the end of August, they will in such a structure flower during the month of December, and much the same may be said of the Paper-white Narcissi. Freesias potted in August are a little later in blooming, but their deliciously fragrant blossoms are always appreciated. Such hardy

subjects as Solomon's Seal, *Dielytra spectabilis* and *Spiraea japonica* flower beautifully in the greenhouse during the winter and early spring months, thus anticipating by a considerable period their normal time of flowering out of doors. Of books such as you require, the following can be recommended: "The Amateur's Greenhouse," by T. W. Sanders, price 5s. 4d., and "Pictorial Greenhouse Management," by Walter P. Wright, price 1s. 9d.

ASPIDISTRA AS A TABLE PLANT (W. H.).—You can certainly, if you wish, show an *Aspidistra* as a table plant; but, however well grown, it would be a weak feature in a collection, as it is of too heavy a nature to compare favourably with the lighter and more elegant subjects that are available. Such plants as *Aralia Veitchii*, *A. filicifolia*, *Crotons* of the narrow-leaved section, many *Dracenas*, and such Palms as *Cocos weddelliana*, *Phoenix Roebelinii* and *Geonoma gracilis* are far more fitted for table decoration than the *Aspidistra*.

BEGONIA DISEASED (Somerset).—Your Begonia is badly attacked by that insidious insect known generally as the Begonia mite, although other plants are often affected by it. Its ravages are greatly on the increase, and, unfortunately, it frequently does a lot of irreparable mischief before its presence is detected. A mixture of soft soap and nicotine, in which the plants should be dipped, is one of the best remedies; but a single dipping will not suffice. On the principle that prevention is better than cure, the house in which the Begonias are grown should be occasionally vaporised with an approved vaporiser.

TREATMENT OF MANETTIA BICOLOR (W. H.).—From your description it would appear that the plant of *Manettia bicolor* has been too cold during the winter, with, perhaps, an excess of moisture at the roots. This *Manettia* succeeds best in what is usually referred to as a warm greenhouse; that is to say, a structure in which the winter temperature ranges from 50° to 65°. It will succeed in an ordinary potting compost of loam, leaf-mould and sand, and throughout the summer will do well in an ordinary greenhouse, or even out of doors. In your case we should be inclined to repot the plant, taking away as much of the old soil as possible without unduly distressing the roots. Then, if kept rather close and shaded, with an occasional syringing, it will, in all probability, start freely into growth.

CHRYSANTHEMUMS: PREMATURE BUD FORMATION (R. H. B.).—Some varieties show buds more persistently than others, and, furthermore, such bud formation is more prevalent in some years than in others. Cuttings taken from the old stems often bear buds too soon. With a few exceptions Nature asserts itself, and growth shoots instead of buds take the lead. Remove the points of the shoots bearing the buds two joints instead of one below such buds, as shoots are more likely to grow from the lower joints. The variety *Mary Poulton* is one of the worst offenders as regards premature bud formation, but the plants generally bear very beautiful flowers, notwithstanding.

ASPIDISTRA LEAVES TURNING YELLOW (A. J.).—It is quite impossible for us to tell the reason of your *Aspidistra* leaves turning yellow so soon after being repotted. It may be that you have allowed them to get too dry, and that might account for the trouble. Excess of moisture would be just as bad. One prominent point to bear in mind in the successful culture of *Aspidistras* is to remember that in a state of Nature they occur on the margins of forests and in similar positions. They are, therefore, essentially shade-lovers, although the mistake is frequently made of exposing them to full sunshine. You ask if you have got wrong soil. That is a question which we, of course, cannot answer; but full instructions were given in the article from which you quote. It may be, too, that when the plant was divided the roots were in a very bad condition, and if such was the case, the old leaves would be very likely to decay before the new roots were sufficiently developed to supply them with nourishment.

KITCHEN GARDEN.

RUST DISEASE ON CELERY (F. W.).—The best way to avoid the troublesome rust disease of Celery is to ensure that the seed sown is not infected with the fungus, as so much of it is. But, as a preventive, spraying the plants at intervals of about three weeks with Bordeaux mixture, commencing now, would be the best measure to adopt.

TOMATO SPOT DISEASE (Tomato).—The Tomatoes are attacked by the Tomato black spot fungus. This is encouraged (1) by too moist an atmosphere and (2) the too free use of manure. Pick off and burn the diseased fruits, lest the fungus spreads. Water the plants at weekly intervals with a solution of potassium sulphate (half an ounce to a gallon of water). Give ample ventilation.

LEAF-CURL IN TOMATOES (Unknown).—Specimens should always accompany questions when possible. Several different causes lead to curling of foliage, and without seeing the type of curl it is practically impossible to say what is its cause. The probable cause is either interference with the water supply or a sudden change of temperature. It may, however, be a hereditary trouble.

MALFORMED TOMATOES (J. R.).—No doubt one or other of the parent plants produced malformed fruits, and that would account for the malformed fruits you are getting. They are quite abnormal, and not of a form that could be attributed to the result of a cultural error. We have found the V.T.H. slug trap a good one for cockroaches and crickets; but where animals are not likely to get to the dead insects, phosphorous paste on bread is a useful poison.

THE GARDEN.

No. 2225.—VOL. LXXVIII.

JULY 11, 1914.

NOTES OF THE WEEK.

Mowing Lawns Without a Grass-Box.—There seems to be great diversity of opinion as to the use of the grass-box, particularly in hot, dry weather. While it is true that to mow without it on tennis or croquet lawns the grass would certainly interfere with the play, still, on large stretches of lawn inclined to get burnt up with the sun, there is much to be said for mowing without the box, as there can be no question that the plants derive great benefit from cut grass being left on the lawn.

A Useful Scarlet-flowered Border Plant.—What a free-flowering plant *Geum Mrs. Bradshaw* is! We have a large mass of it in our garden that has been in flower for many weeks, and still looks as well as ever with its large, semi-double, deep scarlet flowers. It is easily raised from seed, and seedlings come true, so that a good batch can be obtained quickly. The beautiful double white flowered *Peach-leaved Campanula*, *C. Moerheimii*, is also in bloom, and as the two are growing together, they form a pleasing contrast.

An Attractive Bramble.—*Rubus odoratus* is one of the most ornamental members of the Bramble family, forming a rather dense, erect growth. At the present time it is bearing its large, circular flowers of a pleasing purplish red tinge, and on healthy, developed specimens they will often continue to open till September. The large, sweet-scented leaves are broadly five-lobed and irregularly toothed, being very showy. It is an excellent plant for growing under the shade of trees, providing the soil is not too dry. There is a white variety which flowers earlier than the type, and is worthy of cultivation.

The Persian Rose.—What a remarkably fine piece of colouring is seen in this good old plant, its rich golden hue almost defying description! This notwithstanding and a fragrance which is also rich, the plant does not appear in every collection, even where the old favourites are admired to the full. We recently saw it against the house wall in the Rectory Garden, Clapham, near Worthing, and admired it for its richness of colour and free flowering. Because of these good attributes, and because, also, it has played a part in producing the modern yellow Roses, all who love beautiful colour in the Rose should add it to their collection if not already there.

The Pyramidal Rockfoil.—The variety of *Saxifraga Cotyledon* known as *pyramidalis* is one of the most beautiful, and, incidentally, one of the largest, of the alpine Rockfoils in cultivation. It is very robust, and sends out sprays from 2 feet to 4 feet long, bearing innumerable white flowers that are speckled with crimson. It grows best in fissures between rocks, where the long, arching

SAXIFRAGA COTYLEDON PYRAMIDALIS GROWING IN A FISSURE BETWEEN ROCKS.

sprays have plenty of room to develop. If the offsets are removed, larger specimen plants and stronger inflorescences may be obtained, but the rosettes do not, as a rule, attain flowering size in less than two years. It is said that this plant attains far greater proportions under cultivation than it does in its native rocks in the Pyrenees and other mountain ranges of Europe.

The Musk Rose.—This rambling Rose, *Rosa moschata*, is interesting and ornamental, and its scent is delicious. At the present time it is the most conspicuous of any of the species, with its large clusters of white flowers almost hiding the plant. To see it at its best it should be allowed to ramble freely, when it will often throw out shoots 10 feet long, which will form graceful arches of flowers the following year. In the Botanic Garden at Cambridge a large plant has rambled over a Pine tree some 50 feet high, almost hiding it with its clusters of flowers, which look well against the dark foliage of the Pine.

Spiræa Henryi.—One of the most beautiful shrubby *Spiræas* of recent introduction is *S. Henryi*. At the present time this is exceedingly pretty with its many corymbs of white flowers, which are borne most freely on the previous year's growth, forming beautiful arching sprays 5 feet to 6 feet long. Any pruning required should be done as soon as the flowering is over, and consists of thinning out the weak and old wood, the idea being to obtain long, uncrowded branches and to preserve a loose, open habit, so as to display the white corymbs of flower to the best advantage. It is said that the poorer natives of Hupeh, near Ichang (where this beautiful plant was first discovered), use the leaves of it as a substitute for tea.

The Fruit Crop in Oregon.—The Board of Agriculture and Fisheries are informed by His Majesty's Consul at Portland, Oregon, that the estimates of the probable Apple crop, which were made early in the season, seem to have been very much too large. Newtowns blossomed heavily, but a large quantity of the young fruit has dropped from the trees. Spitzenbergs did not bloom so profusely, but they have set better than the Newtowns. Arkansas Blacks have also dropped from the trees to a great extent,

and Winesaps are beginning to do the same. A great many Apples are showing slight discoloration on the stem, which will probably mean further heavy falls, and it will be nearly the time of the Apples going to market before an accurate estimate can be made. These conditions are the result of an early spring followed by cold, wind and rain, which did not prevent the fruit setting, but have caused it to fall afterward.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Tall Delphiniums.—It may interest others to know of the extraordinary growth of some of my Delphiniums. Two large clumps are over ten feet in height and have flower-spikes of 3 feet each, while the blooms themselves are very fine.—B. CHILD, *Ramleh, Walton-on-Thames.*

Sweet-smelling Rosaries.—In last week's issue, page 338, there is a query with regard to sweet-smelling rosaries. A friend of mine who has made them has written the enclosed. He says, however, that his experience is that they do not keep the smell. [Put the petals (any colour or kind) into a metal mortar, and grind them to a very fine paste. The action of the metal will turn the pulp black. If the pulp be not made in this way, it may be stirred with an iron spoon or rod until it blackens. A smooth surface to the beads is secured by very thorough pounding, and this process can scarcely be continued too long. The paste is then rolled with the hands into beads. As these shrink while drying, allowance for this must be made. A row of pins or fine wire nails are driven through a strip of wood, and on these the beads are stuck while drying. The drying process should be conducted slowly, or the beads may crack. They should look, when finished, as if made of very fine charcoal. It is usual to string them with a tiny bright metal bead, either gold or silver coloured, between the large ones].—A. L. KYNASTON.

Rose American Pillar.—With reference to your remarks on Rose American Pillar in your issue of July 4, page 337, I would like the members of the Rose Conference held at the Anglo-American Exposition, Shepherd's Bush, to have seen my specimen; and had they done so I do not think they would have omitted to note it as one of the most beautiful of the Roses which have come to us from the United States of America. I procured my plant from Messrs. H. Cannell and Co. when they introduced it a few years ago, and it has flourished exceedingly, sending up strong canes every season. I cut down the canes after flowering and train up the new growth to take their place. Last year I had nine new shoots, and this year I count over fifteen in good growth. The plant as it now is stands from 12 feet to 14 feet high, with a diameter of from 4 feet to 5 feet. The canes are trained up an iron post, round which is an old wire umbrella, cigar shape, and at the top they meet and hang over. The canes flower from near the ground all the way up and in great bunches. The Rose is a hardy one.—H. G. B., *Forest Hill, S.E.*

A Charming Iris Border.—At Hoddam, Dumfriesshire, the residence of Mr. Edward J. Brook, there was during June a magnificent display of *Iris pallida dalmatica*. It is planted by itself in a long, narrow border beside the extensive aviaries,

and presented a delightful appearance in the third week of that month. From a careful calculation, made by taking a short length of average bloom and multiplying it by the entire length of the border, after deducting a considerable number for errors, there must have been at least 4,000 blooms open at one time in this border. The flowers were of full size, and it can be realised by those who know this handsome Fleur-de-Lis how magnificent was the display afforded by this border. The plants have been in the same position for several years, and have been left without breaking them up. They have done better this year than ever before.—S. ARNOTT.

New Rambling Roses.—I do not think "Dane-croft," whose article appeared on page 317, issue June 20, can know *Neige d'Avril* or *Fraulein Octavia Hesse*, or he would not say "we have no good white in that section." The former was sent out, I think, in 1908, and is one of the

The colour is distinctly white. The blooms are useful for wreath-making, owing to their size, shape and purity of colour. Although not so densely clothed with flowers as some, it is a desirable climber.—E. M.

A Use for Bishop's Weed.—Mr. Smith's "chestnut" relating to Bishops and Bishop's Weed (page 327) is a very old one and has no facts to distinguish it from the merest fiction. *Ægopodium Podagraria*, the Bishop's Weed of modern times, was Goutwort, Ashweed and Herb Gerard of the old herbalists, and was valued, at least on the Continent, for its supposed efficacy as a specific in rheumatic gout. It is remarkable not only for having usurped the place of other herbs in the garden, but its present name of Bishop's Weed belonged to *Ammi majus*, an aromatic annual which is as easy to exterminate as it is difficult to get rid of the former. Gervase Markham, the authority on agriculture and allied subjects in the time of James I., mentions the latter as a veterinary medicine, Bullwort being one of the names he gives it. Gerarde, again, besides the common Bishop's Weed, describes Candy Bishop's Weed, which was a "most principal ingredient" in Venice treacle. This is *Cachrys sicula*, and *Sison perpusillum* is also included under the name. I was pleased recently to see Cow Parsley established in a prominent position in a well-kept English garden.—R. P. BROTHERSTON.

A Beautiful Australian Shrub (*Olearia stellulata*).—The genus *Olearia* furnishes our gardens with several very ornamental shrubby Composites. None of them, however, may be considered perfectly hardy, except *O. Haastii*. Other species, such as *O. macrodonta*, *O. myrsinoides*, *O. m. erubescens*, *O. nummularifolia* and a few more, may safely be grown out of doors if protection be afforded them during severe weather. *O. stellulata* (*O. gunniana*, *Botanical Magazine*, t. 4638), the subject of this note, is one of the most beautiful species of the genus, and the accompanying illustration is from a photograph of

OLEARIA STELLULATA IN THE CAMBRIDGE BOTANIC GARDEN.

finest pure white rambling Roses—flowering on June 20—that it is possible to see. I know of no variety to equal it in any way. The growth is vigorous. My plant is 10 feet high, with handsome, deep green leaves, which form a good base for its clusters of pure white blooms above. The trusses vary in number from five to twelve. The individual flowers measure 2 inches across, and with the deep yellow anthers are superb in appearance and deliciously fragrant. I do not know the origin of this Rose. It was sent to me for trial by Messrs. Bide and Son, Farnham, and right well it deserves to be more widely known. *Fraulein Octavia Hesse* belongs to the *wichuraiana* section, but is exceptionally early flowering for that type, being with me fully developed by the middle of June. Singly the flowers are fully 3 inches in diameter and much like those of *Kaiserin Augusta Victoria* when quite open, and although it produces a few smaller flowers on the same truss, it is not a cluster Rose like so many other sorts.

a plant growing in the Cambridge Botanic Garden. The shrub is 5 feet high and 4 feet in diameter, and is growing in a narrow border at the base of a wall. As will be seen from the illustration, the specimen is flowering profusely, forming a most striking object. The plant is about ten years old. The leaves of *O. stellulata* are alternate, five-eighths to seven-eighths of an inch long, oblanceolate or oblong-lanceolate, coarsely dentate, dark olive green above and densely clothed with stellate hairs upon the under surface. The flowers are borne in close panicles, and individually they are about half an inch in diameter and pure white. For many years seedlings have not, so far as is known, been raised, probably owing to the fact that members of the *Compositæ* are almost always self-sterile. Propagation may be effected by seeds, or by cuttings of half-ripened wood inserted in sand in the spring, keeping them close and shaded. *O. stellulata* is a native of Australia and Tasmania.—R. S. LYNCH.

The Value of Scent in the Rose.—Mr. P. L. Goddard, writing in your issue of June 27, page 329, states his opinion that scent in a Rose is "of much less merit than shapeliness." He sums up his case by saying that the one—the feast for the eyes—is an intellectual pleasure; the other—the feast for the nose—merely a sensual enjoyment. I think this is not a fair way of putting it. It is just as correct to say that the judgment of the eye with regard to a Rose is "a sensual enjoyment"; and surely no one who is competent to speak of it will deny that the beautiful scent of a flower may be "an intellectual pleasure," perhaps unsurpassed in refinement, and capable of appealing to the imagination with poetical suggestiveness. It is not too much to name it as the most ideal of all sensuous delights. Indeed, there is something of magic and romance about the scent of a flower which is as difficult to put into words as they say the rainbow is difficult to paint. I can quite understand anyone calling it the flower's soul, and the simile is beautiful and apt. Shapeliness may possibly require more "intellectual" examination to appraise it, if this is what Mr. Goddard wishes to urge; if it is so, may not this only mean that man can more readily perceive variety and complexity in shape than in scent?—and in this case neither complexity nor variety is in itself the test or the goal, but beauty. All value the Rose for its charm, and to many of us scent seems as great a part of its charm as shapeliness. May I refer to another point? It has probably occurred to Mr. Goddard, as it must have done to others, though I have not seen it discussed. Scent, using the word with the significance we give it when we apply it to the delightful odour of a flower, is, I think, a quality which distinguishes plants, or, let me say, the vegetable kingdom. Buildings, pictures, statues, men and women, animals (with, possibly, a rare exception) may or may not be beautiful to the eye, but they certainly have no "scent" in our present sense of that term. The fact that this delightful quality is confined to the vegetable kingdom makes one half inclined to say that it is a plant's particular glory. And, therefore, when any man "improves" a Rose at the expense of its scent, some of us are tempted to recall the instance of the careless spendthrift who recklessly throws away a good inheritance, perhaps without a thought. It is true that Shakespeare knew only a few old Roses like the Provence and the York and Lancaster, but this point of view emboldens me to believe that, were he now here among all our varieties of to-day, he would still prefer to say, if the florists would let him: "That which we call a Rose, by any other name would smell as sweet."—C. F. GRAY. [We quite agree with our correspondent that scent is a very desirable quality in a Rose. Frau Karl Druschki always reminds us of the Venus of Milo—a beautiful piece of statuary, but without "life."—ED.]

FORTHCOMING EVENTS.

July 14.—Royal Horticultural Society's Exhibition at Vincent Square, Westminster. Saltaire Show (2 days). Arboricultural Exhibition at Hawick (4 days).

July 16.—National Sweet Pea Society's Show at the Royal Horticultural Society's Hall, Westminster. National Rose Society's Show in Sydney Gardens, Bath. Birmingham Floral Fête (3 days).

July 17.—National Carnation and Picotee Society's Show at the Royal Horticultural Society's Hall, Westminster.

PLANNING AND PLANTING THE LITTLE GARDEN.

OUR competition for the best designs for planning and planting the little garden has created world-wide interest, and applications for the site plans have been received from nearly every part of the world. There is still time for new readers to enter, as the completed plans need not reach this office until September 1. We are offering cash prizes to a total value of £33 12s. and a number of book prizes for the best designs. Full particulars of the competition can be obtained by sending 1½d. in stamps to the Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The coupon this week appears on page iii.

EXHIBITING SWEET PEAS.

HINTS FOR THE NOVICE.

THE increased interest in the cultivation of Sweet Peas has been brought about very largely by the competitive and trade exhibits at the various shows. This interest has again reacted, and we have larger and finer exhibits than ever we had, the competitive classes being in nearly every instance well contested. Those gaining premier awards have to place before the judges flowers that are almost perfect in form and colour, and well arranged, not only in the vases, but the various colours of the collection nicely blended or contrasted, so that the exhibit as a whole is pleasing to the eye. In addition to the cultivation of the flowers, there are several points that must be observed before such an exhibit can be put up. In the first place, the plants themselves must be kept most carefully tied in for some two or three weeks previous to the show, as, if allowed to become loose and hang about in any way, the fact of tying them in again will cause the flower-stems to be contorted, and with such material it is almost impossible to arrange the flowers in the vases as they should be.

Shading.—As every exhibitor knows, and as every would-be exhibitor should know, there are certain varieties which, to get them in the best possible condition, must be shaded. Under normal conditions most varieties will stand the sun well; in fact, the colour of many of them is considerably enhanced by it; but certain of the orange, pink, and salmon varieties must be shaded, and this is best done by straining very thin tiffany or Air Shading Material well above the flowers, so as to allow a free passage of air between the blooms and the tiffany, as very hot air takes the colour out of the bloom as quickly as strong sunshine. Commence to shade three or four days before the show. If put on too long beforehand, the stems are apt to become weak and the flowers thin and lacking in colour.

Feeding the Plants too heavily just previous to an exhibition is also inadvisable, though where the exhibitor wishes to exhibit at several shows one after another, say, in successive weeks, he naturally has to keep his plants up to concert pitch, and in such a case, if feeding is necessary, it should be given little and often rather than in heavy doses at longer intervals.

When to Leave Buds.—Where plants may have been rested or have not previously flowered, the buds should be allowed to develop for at least three weeks before the date of the show; and though they may, under

certain weather conditions, develop more quickly than this, such a contingency cannot be relied upon. It is certainly better to have a few blooms going over than not forward enough, and personally I am greatly in favour of allowing the plants to bloom some little time before a show, as, where the plants are not too exuberant, the flowers are much more likely to be of good quality, the individual blooms better placed on the stem, and to open much more nearly at one time. Each of these points is well worthy of consideration.

When to Cut the Blooms.—This is a point that many growers—amateurs in particular—are undecided about, and certainly it is one of much importance to the exhibitor. If the exhibition is near at home, most of the varieties may be left till the morning of the show, and the darker varieties will be improved thereby, as most of the crimson, scarlet, and even rose coloured varieties lose their brightness after a few hours in water, while in most instances the blue, lavender, and mauve varieties will improve in colour with anything from twelve to twenty-four hours in water. If the flowers have to travel some distance, they should always have three or four hours in water before packing. If given this treatment, they will easily stand twelve to fifteen hours in the boxes and come up fresh again, though an endeavour should always be made to get all flowers properly arranged in the vases two or three hours before judging commences, to allow the blooms to expand properly. One point should be rigidly observed, and that is, no matter when they are cut, they should be placed in a very light, airy position, thus avoiding any tendency on the part of any varieties to partially close. If the bunches are thinly disposed in vases or jam jars, they quickly dry, even if wet; and if the weather is very hot and dry, it will be found that they will grow considerably after being cut.

The Age of the Flower when cut is another consideration, and, naturally, one must be guided somewhat by the length of time it will be in water beforehand; but it is a mistake to cut the flowers too young. All the blooms, with the exception of the top one, should be nearly fully developed, with this latter about half open. In this condition the flower should be at its very best in a few hours. Bunches composed of blooms with the top flower or flowers not fully developed look weak, and certainly should not be credited with more points than those just on the turn.

Care in Packing is very necessary, especially if the blooms have to travel a distance; but when the flowers are dry and the stems have been in water an hour or two, this should not militate against the success of the exhibitor. Packed in shallow boxes, or, better still, shallow hampers, with a layer of soft tissue paper between the bunches, they will take no harm; though when the weather is very dry and hot, waxed paper should be used to prevent evaporation. On no account should two layers of bunches be placed one on top of the other. Some exhibitors send their blooms in water, and I cannot say anything against it except that I think it unnecessary when the above details have been observed.

On Arrival at the Show no time should be lost in getting the bunches into water, these being allotted to their various classes as they are unpacked. The exhibitor who takes all his flowers to the show (and I know more than one who does) and relies upon sorting them over there is only making a rod for his own back, it being much easier and quicker at home to select the blooms

and put them together for their various places than in the bustle of an exhibition tent.

Setting Up the Flowers is a tedious operation, but, with a few Rushes or strong grass in the vases, with a little practice one soon becomes expert, and as this is work that may be practised at home beforehand, there is no need for it to be slovenly done. Too spreading an arrangement is not nice, and detracts very much from the colour of the bunch; but at the same time the flowers should not be overcrowded, one bloom barely touching its neighbour. In this way the good and bad points may be easily seen. The arrangement of the colours, too, must be carefully done, placing the strongest and brightest colours where they will have the most effect on the exhibit as a whole, and not merely because as a bunch it contrasts well with its neighbours.

There may be many points that I have overlooked, but I think I have enumerated sufficient to put the exhibitor on the right track, and, providing his flowers are well grown, the novice, if he follows my advice, should be able to do himself justice, even if it is his first time out. **THOMAS STEVENSON.**

ROSE-GROWING IN TOWN GARDENS.

THE great bane of the town gardener—green fly—has been more prevalent than ever this season. The short spells of very hot weather which have been experienced have brought these pests out in alarming numbers, while the succeeding cold periods have checked the growths and rendered them less able to resist injury. One of the benefits arising from judicious pruning and—equally as important—the subsequent thinning out of spindly shoots, is that one suffers less from the plague of aphides, for it will be noticed that it is upon the weak growths they thrive most and are the more difficult to dislodge.

Those who have practised removing them by hand have been hard put to it, while spraying seems to have given only temporary relief. When the former method is employed, a good plan is to take round a basin of soapy water, into which the finger and thumb can be dipped before they are drawn up the growth. Not only is it much easier to remove them then, but it avoids soiling the hands, and the young shoots are less likely to be bruised and injured. When the insects congregate round the base of a bud, they are not difficult to remove, but more trouble is experienced when they are found between leaves that are just expanding. If the shoot is long enough, it can sometimes be dipped into the basin and thus cleansed; but otherwise, and if it is not

desired to spray, soapsuds placed on the growth will usually prove effective. After the blooms have started to expand, any green flies that get in should be removed with a small brush. Considerable care is needed in using a syringe at this stage. It is not advisable to indiscriminately spray Roses that are opening, for fear of soiling them, so that any spraying should be done at close quarters. It is always well when doing this to try to avoid ladybirds and their grubs—the latter small blackish insects with yellow spots on their backs. I do not think insecticides kill them, but they are likely to discourage them in their efforts, and they certainly deserve a better welcome,

under sides of the leaves only, leaving the upper tissue intact. This insect is of exactly the same colour as the leaf, and in its early stages is so tiny that it is very difficult to detect. The spoiled foliage shows where it is, however, and by turning over and examining all spotted leaves, further damage can be avoided from this source.

Even when the most careful spraying has been done, some mildew is certain to appear about this time. Frequently it may be found first upon the stem of a bud or flower, as these will naturally have been avoided to some extent. It is as well to have a small quantity of wash at hand for immediate use, for, by rubbing a little over the part affected, a great deal of future trouble may be saved. Leaves that are whitened should be removed and the tree sprayed thoroughly. **P. L. GODDARD.**

WORK AMONG THE ROSES.

ONE of the main points among Roses during this month is budding, but, as special notes appeared in last week's issue, page 345, it is left out here. A point that is not sufficiently borne in mind is the great help towards future growth and blossom that can be readily afforded if one pays more attention to the prompt removal of all old blooms and seed-pods. As these notes appear, the majority of our gorgeous blooming climbers and weepers will be carrying their main crop of blossom. Cut off the spent pods and trusses as soon as the petals have fallen. Too often this is neglected in the case of plants growing on walls and houses, also over large arbours and pergolas. It would not be so did more people realise the exhausting process of developing pods for seed. Naturally, the main strength of the plant goes here, and even the failure to ripen is a considerable strain. Not only is it wise to cut these off, but the flowered break itself might well be curtailed more than half its length upon all varieties of normal growth, and thus retain the plant in better shape and avoid so much tendency to bare bases, which cannot fail to be unsightly.

There is not enough attention given to a little judicious summer pruning in most gardens, and, wherever possible, as much as can be cut away of the wood that has already flowered should be done earlier, thus putting additional strength into the more valuable growths for next season's chief display. Almost all of our extra vigorous growers give their best from such young wood, and a few longer rods are of more use than a mass of crowded laterals, which would result in even less bloom eventually, as well as being far more difficult to manage or train in any desired direction. This younger growth can be kept cleaner and more

ROSE QUEEN OF FRAGRANCE, A NEW VARIETY THAT SECURED THE CUP OFFERED AT HOLLAND HOUSE SHOW FOR THE BEST SCENTED NEW ROSE. (See page 356.)

for each accounts for a good number of green flies in a day.

Those who can obtain rain-water should always use it in mixing insecticides. When hard water is used, they are not nearly as effective, and usually the lime is precipitated, so that a white deposit is left upon the surface of the leaves unless a thorough syringing with clear water is subsequently given. This is both unsightly and harmful to the foliage.

Of the many grubs which visit us at this time, one of the most difficult to catch is a caterpillar that commences life by eating tiny holes in the

healthy than older wood; in fact, quite a lot of diseased and deteriorating wood is avoided. The strongest growths that were pegged down may be cut away as soon as they have done flowering. This will allow of better working among them, as one can get around the stems more freely. By this time, too, most of this class of Rose will be making its strongest and most valuable breaks from the base, which always mature better when allowed to grow in a more natural and upright manner. With a little careful but efficient securing these can be cleansed easily, both as regards the soil and foliage. Hoed between, and a little mulch lightly forked in, do wonders in helping these growths.

After the first flush of growth and exhaustion of soil, almost all will benefit from free and copious waterings if the soil is at all upon the dry side. During a showery season a few sprinklings of artificial manures will be of great service, their feeding properties being washed down naturally and with less loss from exposure to a dry atmosphere. In almost all cases these manures are of more value when watered in or lightly forked into the soil, should rain be absent. Do not err in giving half waterings. It is surprising how much water it needs to properly penetrate to well-established roots, more especially in the case of vigorous growers upon walls, fences and arbours, which so seldom get enough to do real good. Little and often is not the correct plan here.

Because the bulk of our summer bloom is now over in most gardens containing the older varieties, there should be no check as regards persistent washing and the use of the hoe. It is from now onwards that so much mildew, red rust and black spot gains a firm hold for the autumn, and often ruins what would otherwise be quite as welcome a show as the first of the season.

Pot Plants from under glass will do better outside now if properly attended to. I fear there is much neglect at first with these, and they often suffer severely the first week or so after removal to the more drying influences of the open air. Water and attend to them with more care if you wish to get the best results from well-matured growth later on, and it is only from this that one can expect success when forcing. A. P.

ROSE PINK PEARL.

THIS I look upon as one of the best of the less rampant pillar Roses. The blooms are produced freely on rather short growths, and in the opening stages are extremely pretty, the colour being a delicate shade of buff pink. It was sent out a couple of years ago by Hobbies of Dereham, and was the result of a cross between Una and Irish Elegance. In growth and form of flower it takes after the first-named variety. If given liberal treatment, it soon makes a plant some 7 feet or 8 feet in height, and blooms over quite a long season. It is useful in a cut state for filling small vases for the dinner-table, its somewhat wiry habit of growth making it particularly suitable for light decorative schemes. THOMAS STEVENSON.

ALPINE PHLOXES.

THESE charming rock plants do not seed freely, but may easily be increased by cuttings during July and August. *P. subulata* and its varieties are well worth growing, and part of the old plants should be divided each season, for if allowed to become too dense they are apt to damp off during the winter.

THE DIANTHUSES OR PINKS.

(Continued from page 340.)

D. fimbriatus.—This may be commended for rougher rockwork or for the border. It grows about a foot high, and has good, fringed, pink flowers about June and July. It is of easy culture in light soil.

D. Fischeri.—This Dianthus is now less common than at one time. It does well in the border or on the rockery, and has grassy leaves and a number of blush or lilac fringed flowers. It is about nine inches high, flowers in the summer, and is easily cultivated in dry soil. *D. Fischeri* is now referred to *D. chinensis* as a variety of that species.

D. fragrans.—Although catalogued by some as about a foot high, it is often less. It makes nice clumps, with sweet-scented, white flowers,

would include among the hybrids *Rose de Mai* and *Progress*, with others of the newer race of perpetual-flowering Dianthus. *D. alpinus* × *superbus* is a new hybrid, and *D. Spencer Bickham* is a choice little crimson Dianthus for the moraine. *D. Atkinsonii* is a lovely double rose hybrid Pink.

D. integer.—This is a dwarf plant with white flowers, but I am doubtful if the true plant is offered, as that to be found in gardens has fringed blooms. In the "Kew Hand List" this plant is referred to *D. strictus*.

D. Knappii.—Uncommon, because one of the few Pinks with yellow flowers, *D. Knappii* deserves consideration, although its flowers are individually small. They are in clusters on stems 6 inches to 9 inches high. Easily raised from seeds and grows well, but apt to die off after flowering. May to July.

D. monspessulanus.—The Montpelier Pink grows 6 inches to 12 inches high, and has solitary, clear rosy pink flowers of fair size, but not specially

DIANTHUS SPENCER BICKHAM, ONE OF THE BEST HYBRID GARDEN PINKS.

and is highly pleasing in the summer. There is a double variety. Easily grown on the rockery. June and July.

D. gallicus.—A white-flowered species, rather greenish towards the centre, and solitary on stems about six inches high. An easy species in dry soil, flowering in late summer.

D. hybridus.—Under this name we have grouped a great variety of Dianthus. The most prominent of these, especially for the border, are generally known as the Mule Pinks. The greatest favourite of these is *Napoleon III.*, with blood crimson flowers, and splendid in the border. Like some of the other hybrids, it often flowers itself to death. If cut down immediately after flowering, this and other hybrids generally produce enough "grass" for propagating. Other good hybrid Pinks are *abbotsfordiana*, rosy scarlet; *Emile Pare*, rose; *Fettes Mount*, rosy pink; *Fürst Bismarck*, scarlet; *Lady Dixon*, cerise; *Marie Pare*, white; and *multiflorus*, rose. Some also

attractive, though useful on a large rockery. *D. alpestris* is now referred to this. There is a good white variety, *D. m. albus*. May and June.

D. petraeus.—A dainty, easily grown rock Pink with many small rose flowers. It is a capital plant for trailing over the rocks or a wall. The variety *albus*, white, is very pleasing, and there is a choice little double white variety worth growing. June.

Dumfries.

S. ARNOTT.

(To be continued.)

SUMMER PRUNING FRUIT TREES.

TREES and bushes should be gone over at short intervals, and on no account preserve shoots that would require to be removed in the autumn. This work can be done by pinching with the finger and thumb. A note should be made of all trees that have failed to fruit through over-luxuriant growth, so that they may be root-pruned in the autumn.

WORK AMONG BULBOUS PLANTS.

THAT there is much important work requiring to be done during the month of July in connection with bulbous-rooted subjects, no one gardening largely with these plants would attempt to gainsay. In some measure its importance lies in affording the plants (roots) a good rest after a season of toil. We have had their harvest of flowers, and should in like manner consider the bulb harvest if we would reap a further golden harvest next year. The "golden harvest," though it may apply directly to certain Daffodils, may also apply to others not "golden"; hence, figuratively, it may apply to all classes of bulbous flowers that may be dealt with now. It is only another way of saying that work of this kind should be done at the right time if the best results are to be desired.

I say this much advisedly, since it is within one's knowledge that not a few classes of bulbous plants are left in the ground, and only thought of when planting-time comes round again. To lift them then—and, unfortunately, it is often done by many an amateur—is a most dangerous practice, and one which merits the strongest condemnation. The danger, of course, lies—in the case of the Daffodil, for example—in that re-rooting has already begun, in some considerably advanced, and, as the root-fibres of a Daffodil disturbed after once emitted from the bulb never retake to the soil, or, as in some other plants, break into root-fibres again laterally, the plant (bulb) is thrown on its own resources, and greatly exhausted by the processes of growth and flowering which follow. This naturally produces debility, and the worst results may ensue. Hence there is need for doing the work in season and in reason. With certain plants—Daffodils, Tulips, Spanish and English Irises and *Lilium candidum*, for example—that season is now.

It does not follow, however, that it is essential to success to lift all Daffodils each year. There are great differences of soil and of varieties, and the former exercises considerable influence on the latter. In cool, moist loams the Daffodil may go on and flower and increase for years, building up in that time a stature and vigour of its own. In lighter soils these things with refinement are best preserved and encouraged by annual lifting, by affording the plants a short though absolute out-of-ground rest, and by soil cultivation and enrichment. The commercial grower of these flowers of necessity lifts his crop of bulbs each year. It pays him to do it. He is equally smart and prompt about early replanting, for he knows that pays also. For the amateur, and for garden purposes generally, a modification of the annual lifting will be found to answer well. But where lifting has become

necessary, the amateur cannot err by indulging in early replanting. In other words, the choicest and most exacting of white-flowered Daffodils wants no more than a month's holiday each year, while some of the Poeticus race, because of their continuous rooting, are best without drying at all. The drawbacks to non-lifting of the Daffodil are overcrowding, bulb deterioration and sparse or non-flowering. To lay down hard-and-fast rules for all, having regard to varieties and varying soils and localities, is not possible. The amateur, however, who takes the above as the signs of the times, has already at his command a finger-post which will also prove an unerring guide. Crowded clumps of Daffodil bulbs will, with lifting and exposure to air—not sun—break up readily, while bulbs of the "breeder" or

house shelves; having seen them there prompts the warning. Such bulbs do not need to be roasted alive. In the dry state the Tulip is capable of much endurance, and loses but little in comparison with other bulbs.

English and Spanish Irises.—These are June flowers, and as they go to rest soon after flowering may be lifted almost at once, though any time during July will do quite well. These, like the Tulips, are spare rooting, and they pay for the rest, which also permits of the separating of the bulbils from the mother bulb for planting apart. Moreover, as among the most precious for service in the cut state, they merit encouragement, and should be grown by all. Among their good attributes are cheapness, simple cultural requirements and free increase. But there are other classes of bulbs, less well known, perhaps, of which something useful might be said in another chapter, which, with the Editor's permission, I will refer to anon. E. H. JENKINS.

A BEAUTIFUL PILLAR ROSE: PINK PEARL.
(See page 353.)

BROMPTON AND EAST LOTHIAN STOCKS.

THEIR ORIGIN AND CULTIVATION.

ALL Stocks are delightfully sweet, but none is so grand with sweetness of perfume as the old Brompton, which first appears by that name along with the "Twittenham" early in the eighteenth century. The plants attain a height of 3 feet to 5 feet, and it is a moot point whether the large double forms or the exceedingly floriferous singles are the more attractive; the latter I should say, certainly for picking. Very unfortunately, the plant is not so hardy as all of us would like, hence it is all but unknown in many parts of the country. One of the important cultural items never to be lost sight of is to manage the treatment so that the plants are enabled to withstand our winters and renew growth with vigour in early spring. Seeds should be sown at once, preferably in an ordinary cutting-box in light, friable soil, and protected

in a cold frame from sun and rain till the seed-leaves are fully formed, after which no protection is needed or appreciated. While still small, transplant in the reserve garden on a piece of ground fertile enough to cause a steady but not over-vigorous growth, and it will not be amiss to again transplant before autumn gives place to the damp and cold of winter, or from September 10 to September 20, so that they may have time to get over the check to root action previous to winter, but not to advance top growth.

In the Case of the Tulip, annual lifting is an essential, equally for the preservation of the bulb and for providing fine flowers, or, indeed, flowers at all. The Tulip is a meagre-rooting subject, and the few thin, wiry root-fibres it produces are annuals pure and simple; hence this highly popular and decorative plant should be lifted each year and rested long—certainly not less than two months, and with impunity three. After lifting, see to it that the bulbs are not exposed to strong sunlight or sun-heat. They are better, indeed, placed at once in shallow boxes in any airy shed or outhouse, or even a shady place where sun cannot reach them. Avoid putting such things on green-

About the middle of February the plants will be ready to appropriate surface-dressings of pigeon-manure, soot or artificials, or all of them, the ground to be well stirred at the same time, and, closer than 3 feet apart, that space should be

provided by lifting enough and planting elsewhere. A sheltered position, where sudden thaws after frost do not occur, and protection from cutting winds are very important. The single varieties are lovely for cutting in spring and early summer, but they foul the water in a very brief time, and it is essential that it be changed frequently and the stems of the Stocks washed at every renewal.

East Lothian Stocks were discovered in a farmer's garden in East Lothian by Mr. David Thomson, then of Archerfield, and by him brought to public notice shortly previous to 1860. Recently the colours have had several important accessions, and there has been also for many years a type with glaucous foliage called "wall-leaved," but it is not so effective, in my opinion, as those of the grey-leaved section. All Stocks are propagated from seeds saved from selected singles, and a large batch of singles ranged in colours at the base of the south or west walls of an old Scottish garden in April and May is a sight worth going a long way to see. But the flower-growing public want doubles, and so, when a few singles appear among the former with their Hyacinth-like spikes, the seedsman for a few moments comes in for a depreciatory sentence, for which, on the whole, there is no reason.

Some people sow the seeds of East Lothian Stocks in September and grow—or rather permit the plants to exist—in a cool, dry glass structure till spring, and then let them grow away. For ordinary purposes the end of January or the first week of February is quite soon enough to sow, the seedlings appearing in a few days when the seed-boxes are placed in warmth. But a cool, dry, airy treatment is best, the seedlings being apt to damp off otherwise. When damping is apparent, water must be applied with the utmost caution, dipping the boxes so that no moisture rises to the surface and wets it. Sand dried by heat in an oven and sprinkled among the seedlings is a certain remedy for this disease. If only a few plants are grown, they may be forwarded either in boxes or pots. I prefer transplanting into shallow soil beds in cold frames, from which they are ready early in May for planting into the flower-beds. They grow extremely rapidly when left longer in frames, and if it is inconvenient to plant till later, the lines between the plants should be pierced with an edging-iron to sever the roots.

A week or nine days should elapse between this root-pruning and planting, and the benefit is seen in the plants flagging scarcely at all. These Stocks do best in soil well enriched with rotted manure, made somewhat firm and not permitted to become dry in times of drought. The best of the plants, if lifted in autumn, are useful for the greenhouse in spring, but it is better to sow in April or May and grow these specially for pot culture.

Tynninghame, N.B.

R. P. BROTHERSTON.

SEASONABLE NOTES ON VEGETABLES.

Cabbage.—A sowing should be made the third week in July for the production of early spring Cabbage. Ellam's, Sutton's April and Flower of Spring are desirable varieties. The former, although it has long been in existence, is still reliable, producing perhaps fewer "bolters" than any other variety when the stock is true and the cultivation of the right order. What is wanted to ensure success is stocky plants, not too luxuriant nor drawn up weakly by overcrowding, which is the result of sowing the seed too thickly. An open site recently manured and deeply dug should be selected. If the soil is dry,

it is yet too early to apply the blanching material. Liberal treatment of Cardoons is a necessity to obtain large succulent plants. Copious supplies of liquid manure in trenches around the plants are what is required to enable the plants to make good progress. Should the weather continue dry during July, nightly syringings of the plants will be an advantage in stimulating growth.

Celery.—For late use make further plantings. Where space is not too plentiful, two and as many as three rows may be planted in the one trench, which is distinctly a saving of ground. The only point against this is the difficulty experienced in earthing-up the plants later on. With care this is easily done. Water regularly newly put out plants, and dust the leaves frequently with soot to ward off attacks of Celery fly.

A VIEW IN MESSRS. R. WALLACE AND CO.'S EXHIBIT OF JAPANESE IRISES AT HOLLAND HOUSE SHOW. THIS WAS AWARDED THE CORONATION CUP OFFERED FOR THE BEST EXHIBIT IN THE SHOW.

give it a thorough soaking the day before sowing the seed, break up the soil finely, rake the surface smoothly over and sow the seed thinly. It is better to have a larger bed than to sow thickly. Cover the seed with fine soil with which wood-ashes are added, as a preventive against the Turnip fly. If the weather continues dry, shade the bed with mats or green boughs until the plants show through the soil; then remove the shading and cover with a net to prevent birds taking the seedlings. Sprinkle the bed nightly to encourage rapid growth. Should the plants be too thick in the beds, remove a few directly they are large enough to handle, which can be transplanted to another bed, and thus give space to those retained, which are certain to be of the right kind for future use.

Cardoons when growing vigorously require support to prevent them falling on one side, as

Endive.—For autumn and winter supplies preparations should be made by making a sowing now. This will succeed on the top of a Celery ridge for economy of space. The next sowing should be made early in August on a warm border in a well-prepared bed of rich soil, as the plants from this sowing should be encouraged to grow quickly. Directly the plants are large enough to handle, they ought to be put out where they are to remain, as they transplant so much better than when larger. In thinning the rows, those remaining will naturally be the first ready for use. Keep the hoe going among them, especially during dry weather.

Leeks for exhibition should have every encouragement given them to grow freely. If they do not thrive at this stage, they cannot acquire the full size when show-time arrives. Liquid manure in quantity to the roots and overhead syringings

with clear water in the evening are an absolute necessity to obtain success. Blanching must continue, too, as growth progresses, to obtain the necessary 16 inches of clear stem which is considered to be an essential to success, and necessarily, of course, a due proportion in thickness. Stiff brown paper collars about six inches long are what are generally used. As the plants grow, others are added. Place a small stick as a support on each side of the plant with the paper over it. Plant out a batch on open, flat ground for general use. Use a dibber, making quite a deep hole. Leave it open, gradually filling in as growth progresses, thus procuring stems from 8 inches to 1 foot long, which for ordinary use are useful and obtained with but a minimum of labour expended. Deeply trenched ground, with abundance of manure added, is necessary for this mode of culture.

NEW PLANTS AT HOLLAND HOUSE SHOW.

FIRST-CLASS CERTIFICATE.

Hypericum Læve rubrum.—As shown this unique subject was 15 inches to 18 inches high, shrubby, like many of its class, the stems thickly beset with narrow, almost wire-like leaves of an inch or so in length, and terminated by clustered corymbs of somewhat starry flowers of flame red colour. Unique in its class, it is equally so in that delightful set of sub-shrubs that ever find a warm welcome in the rock garden. A neat and pretty habited plant of rare distinction and merit. From Messrs. Bees, Liverpool.

AWARDS OF MERIT.

Carnation Gordon Douglas.—A handsome self border variety of rare petal substance and rich

Amaranthus Dr. Martin.—The crown of central tuft of leaves is almost wholly scarlet, the lower leaves of similar tone in the basal half, and olive green and tinged with copper in the upper half. As a summer bedding plant it could be used with great effect. From Mr. W. E. Upjohn, Worsley Gardens, Manchester.

Sweet Pea The President.—A really good addition to those having brilliant orange scarlet flowers. Shown by Messrs. Alex. Dickson and Sons, Belfast and Newtownards.

Iris Mikado.—Virtually a Morning Mist—the most gorgeous of the water-loving Irises of Japan—done in white and rose, the former the groundwork, the latter the reticulations or veins in a particularly handsome flower. The standards, too, are prominent and broad, and coloured a reddish violet hue. From Messrs. Wallace and Co., Colchester.

Campanula garganica W. H. Paine.—A typical garganica in habit and freedom, with flowers of deep blue and a clear white base. These colours are nearly equally divided, the result being a very distinct and effective variety. Exhibited by Messrs. W. Watson and Sons, Dublin.

Gladiolus Mrs. Atkinson.—One of the early flowering race, the flowers of a pronounced salmon-pink hue. From Mr. C. B. Blamfield, Guernsey.

Carnation Chelsea.—A good novelty in the fancy section of the perpetual-flowering class. The ground colour is white, copiously striped with scarlet, particularly in the upper parts of the petals. The flower is of large size. Shown by Mr. A. F. Dutton, Iver, Bucks.

In addition to the foregoing Messrs. William Paul and Sons, Waltham Cross, were awarded the Clay Challenge Cup for a Rose not in commerce possessing the true old Rose scent. The cup is a silver-gilt one of the value of £75, and is open for competition annually. This year Messrs. Paul have won it with their new seedling Rose Queen of Fragrance, which is large, of rose pink colour and has exquisite perfume. See illustration on page 352. The vase of its flowers was greatly admired.

CARNATION GORDON DOUGLAS, A BEAUTIFUL NEW CRIMSON BORDER VARIETY.

Spinach.—A good batch of seed should now be sown in drills 16 inches apart to stand the winter, choosing an open site on deeply dug soil. That from which a crop of early Potatoes was taken will answer well. Either the round-seeded or prickly varieties will suffice. So many persons think the former is not sufficiently hardy for winter use. This is a mistake. One sort answers equally well with the other.

Parsley.—Now is a good time to sow seed for a batch of plants for winter and spring use. A raised edging to a path is a good site for this crop; it is so handy for picking during wet weather, especially where the soil is heavy and sticky. When the plants are large enough to handle, thin them out to 9 inches apart. Keep the soil well hoed to encourage freedom of growth.

Swanmore, Hants.

E. MOLYNEUX.

perfume. It is a glowing crimson scarlet. The flowers are of large size and peerless form. From Mr. James Douglas, Great Bookham.

Gladiolus Radiance.—This is one of the early flowering set, orange scarlet in colour, the three lower petals of crimson hue, with white flame or feather on each. Exhibited by Messrs. E. H. Wheadon and Sons, La Couture, Guernsey.

Rose Waltham Scarlet (H.T.).—A single perpetual-flowering bedding variety of much excellence. The plant is very free-flowering, and certainly most brilliant and effective in colour. From Messrs. William Paul and Son, Waltham Cross.

Sweet Pea Mrs. Hugh Wormald.—One of the most distinct of the new Sweet Peas of the present year. It is quite a break away, a bicolor of a distinct type. The standards are pink, the wings of a creamy tone. From Messrs. Hobbies, Limited, Dereham.

NEW ORCHIDS.

Three first-class certificates were awarded, viz.: *Cattleya Irene*, a white hybrid shown by J. Gutney Fowler, Esq.; *Miltonia vexillaria* illustris, from Messrs. Sander and Sons; and *Odontonia cleverleyana*, a remarkable bigeneric hybrid between *Miltonia* and *Odontoglossum*, from Messrs. Mansell and Hatcher.

Awards of merit were granted to the following: *Cattleya Warscewiczii Meteor*, from Lieutenant-Colonel Sir George Holford; *Odontoglossum eximium Solum*, from Messrs. Charlesworth and Co.; *Odontoglossum Invincible* and *Miltonia Sanderæ Enchantress*, from Messrs. Sander and Sons; *Lælio-Cattleya Aphrodite Our Queen*, shown by Messrs. Stuart Low and Co.; *Miltoniada vuystekeana insignis* (*Miltonia bleuana* × *Odontioda Charlesworthii*), from M. Firmin Lambeau, Brussels; and *Renanthera pulchella*, from M. A. A. Peters, Brussels.

GARDENING FOR BEGINNERS.

THE SUMMER PRUNING OF HARDY FRUIT TREES.

A.—NOS. 2 AND 2 SHOW POINTS AT WHICH SUMMER PRUNING SHOULD TAKE PLACE.

CULTIVATORS did not, a generation ago, attend to the summer pruning of their fruit trees as closely as they do now. One saw, in a few gardens, the young shoots partly broken

off and depending from the older branches; they were, in due course, cut away altogether. There are two reasons why shoots should not be left on the trees in a partly severed condition, namely, because they obstruct the air and light, and so prevent, to some extent, the ripening of the basal part of the branch, that part containing the buds which are to be retained for use in the following year; and because, being blown to and fro, they bruise the young fruits.

A Suitable Time to Prune.—If this work is done in June, the basal buds on the shoots that are shortened will, most probably, grow, and this condition would be disastrous to the welfare of the tree pruned. The middle of July is quite soon enough to begin the work, and it may be continued into the early part of August; in Northern Counties, to August 20. The ordinary pruning of the current year's shoots on young branches growing from two and three year old stems is shown in Fig. A. No. 1 shows a shoot duly cut back, and Nos. 2, 2, the points at which other shoots must be cut back. Fig. B shows how the cultivator should summer prune a young tree. The leading shoot, No. 1, need not be cut at all; the others, as denoted by the dark cross-lines, Nos. 2, 2, must be cut as shown. Any small shoots growing near the centre of the tree, and which, if left, would prove of little value to the cultivator and tend to cause undue crowding, should be cut out entirely, as denoted by the two cross-lines, No. 3.

Treatment after Pruning.—In the course of ten days or a little more, a robust tree will, after being pruned, begin to push out young shoots at the end of the pruned branch, as shown at No. 1 in Fig. C. All should be pinched out when about an inch long. In three weeks' time more young shoots will appear from the axils of the same main leaves; these young shoots will be weaker than the others, but must be pinched out too. After this date the wood of the tree begins to ripen rapidly, and no more shoots will grow to the extent that they will need removal before the winter pruning is done.

While the young shoots are growing at No. 1, the basal buds, No. 2, will be dormant and not grow; but they will continue to swell, and ripen later, forming plump buds.

B.—SUMMER PRUNING A YOUNG TREE.

The winter pruning means cutting the summer-pruned shoot back to No. 3. Shoots growing from old spurs must be dealt with in the same way.

On large stems of trees there are, very often, a number of young, long-jointed shoots growing, as shown at Nos. 4, 4. All such must be cut off quite close to the bark of the large branch, unless any of them are required to fill up large gaps in the tree.

G. G.

RAISING ZONAL PELARGONIUMS AND FUCHSIAS FROM SEEDS.

It is a very interesting occupation raising plants of the above from seeds. The resultant plants are,

usually, very strong-growing and quite suitable for greenhouses in town gardens. The flowers of Pelargoniums from seeds are perhaps not quite as refined as those on plants raised from cuttings, but if the plants are properly treated they yield a grand display of blossom in a comparatively short space of time.

Procure some shallow pans, put in crocks, then a few leaves. On the latter place a layer of nice gritty soil, rather more than three parts filling the pans with the compost. The latter must be made firm, and watered through a fine-roset watering-can. After the soil has drained for an hour, drop the seeds on the surface 1 inch apart; cover them with similar compost a quarter of an inch deep, and put the pans in a warm position in the greenhouse. Do not cover the pans with squares of glass or paper, but see that the soil is maintained in an even state of moisture. This can be ensured by holding the pans in water when necessary, and allowing the water to soak the soil upwards. It is advisable to sow the seeds thinly, because the resultant seedlings must be left undisturbed until they are about an inch high, as before they reach that stage they possess very few roots. Transplant them 2 inches apart in boxes 4 inches deep, filled with a good compost made moderately firm. Again afford the young plants the benefit of a light position in the greenhouse.

For the first potting use a compost of loam and leaf-soil in equal proportions, mixing with it some road grit or coarse sand, a small quantity of well-rotted manure and old mortar rubble. B.

C.—AFTER-EFFECTS OF SUMMER PRUNING.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Melons.—The latest plantation of Melons may be made about the third week in July, and for the plants a gentle bottom-heat should be provided, so that the growth may reach the top of the trellis before the season is too far advanced. Keep surplus shoots well thinned out, and when the flowers are ready to pollinate, endeavour to secure three or four on each plant at the same time, so that the fruits may swell evenly and as quickly as possible.

Cucumbers.—Seeds for early winter supplies should be sown at once, and again a fortnight later. Sow the seeds singly in small pots, and, when the young plants are well through the surface, keep them near the roof glass, so that they may not become drawn.

Cherry Trees in Pots.—These trees may now be removed to the open garden, and should receive careful attention as to watering for the remainder of the season. Syringe freely, and if insects appear, Quassia Extract will be found a sure and safe remedy.

Plum Trees in Pots.—These should also be removed to the open as soon as the crop has been gathered. Plunge the pots in a bed of ashes in order to reduce the necessity of frequent watering. Manure-water from the farmyard may be applied frequently.

Plants Under Glass.

Chrysanthemums.—Late-struck plants which are intended for decorative purposes should now be potted into 6-inch pots. If two or three cuttings have been struck in each pot, they may be potted as they are, and if stopped about the end of July will make useful plants in the month of November.

Primula sinensis.—There is still time to sow seeds of *Primula sinensis*, and, if these are carefully grown, good plants may be available during the spring. If sown in finely sifted soil and placed in a cool pit, germination will soon take place. The pans should be covered with sheets of paper over the glass to keep the soil in a uniform state of moisture and to reduce the need for watering.

The Plant Stove.—Many of the spring-struck plants will benefit by a shift into larger pots. Aralias, Crotons and Dieffenbachias should never be allowed to become stunted while in a young state, or the colour of the foliage will be seriously affected. Strong heat and plenty of moisture will be necessary to promote free growth.

Gerbera Jamesonii.—Seeds of this beautiful flowering plant may be sown now in pots or pans of sandy peat. Place in gentle heat, and when the seedlings are large enough to handle they may be potted into peat and loam, with sufficient sand to keep the soil from becoming sour. They will flower about Easter.

The Shrubberies.

Pruning Plants.—Many of these in this department will now require attention either with the knife or the pruning secateurs, in order to keep them within bounds. Take care to cut the common sorts well back, so that the choicer varieties may have room to develop; but at the same time these choicer permanent subjects will benefit by judicious stopping, in order to maintain compact growth without interfering with their natural beauty. The ground between the plants should then be hoed and raked to give the place a tidy appearance. Spring-planted subjects should be examined and, if necessary, a good watering given.

Hedges of Box, Yew and Laurel may now be cut into shape, and where it is desirable to avoid a formal appearance, the pruning-knife should be used in preference to shears.

Ornamental Climbers.—A judicious thinning and regulating of the shoots should now take place, but care must be taken that none of the flowering branches is removed while this work is being done.

The Fruit Garden.

Late Strawberries.—Those on north borders should be well supplied with moisture at the roots while the fruits are swelling. The fruit

trusses may be lifted up and placed in small forked sticks. The bedding material should then be drawn close under the plants to prevent splashing by heavy rain. Waterloo is our best late variety at Frogmore, and fresh plantations are made each season, the best fruits being produced by plants of one year's growth. When the fruits are colouring, netting should be placed over the plants at some distance from the foliage, or the fruits will be pressed into the straw and very soon decay.

Plum Trees.—Those on walls and in the open garden should be frequently syringed in order to destroy aphids and other insect pests. Quassia Extract will be found a reliable insecticide if used according to the makers' directions.

Morello Cherries.—Trees should be carefully examined for the presence of black fly, which generally infest the tops of young shoots about this time. These may be freely syringed until the fruits approach the ripening stage.

Sweet Cherries.—The tops of the young shoots may be carefully dipped in some insecticide, which must never be allowed to reach the fruits.

The Kitchen Garden.

Late Peas.—The sticks should be placed in position as soon as the plants are a few inches high. Give a liberal supply of water at the roots and mulch the soil between the rows with manure from the farmyard. The same remarks apply to French Beans and Scarlet Runners.

Cabbage.—A small sowing should be made at once and the plants put out as soon as large enough. The ground for this purpose ought to be rich, but moderately firm. A sowing made early in August may be the most profitable, but with a mild winter the early sown plants come into use when other green vegetables are scarce.

French Beans.—The latest sowing in the open should take place at once. Choose a sheltered position for the purpose and sow the best early variety available. The Belfast Bean is sown here for this purpose, and gives great satisfaction. Plants from which supplies are being gathered should be freely watered during dry weather. Keep the pods picked off as soon as large enough, whether they are required or not, as this will encourage the plants to bear for a longer period.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Broccoli.—Where space is limited it is sometimes difficult to find room at the moment for this important crop. However, now that the early Potatoes will have been lifted, no time should be lost in getting them planted. This ground should not be dug or forked. All that is necessary is to clear off weeds and other rubbish, as the firmer the ground is kept, the more likely will the plants pull through a severe winter.

Savoys.—It will be as well to make another planting of these to follow those planted some time ago. In the case of Savoys, preference should be given to the small curled varieties, as these are not so likely to be damaged by frost as the larger ones.

Cabbage.—In cold districts where growth is not so rapid, a sowing should be made now of those intended for spring cutting. For this sowing I have found nothing to equal Harbinger and Sutton's April. This year we started cutting useful heads of the former during the last days of March, and out of a large plantation we did not have a single plant that bolted.

Winter Greens.—The planting of all winter vegetables ought to be completed without delay. Those planted earlier should have the soil drawn up round the stem, and to encourage growth give an occasional dressing of superphosphate and soot.

Lettuce and Spinach.—It will not be too late to make further sowings to keep up the succession of these indispensable vegetables. In doing so it will greatly assist the hastening of the growth if the seed is sown thinly, and, again, if the young plants are thinned as soon as they can be handled.

The Flower Garden.

Pansies and Violas.—Where these are grown from seed, the present will be a suitable time to make a sowing. In many cases this sowing could be made in the open border; still, to avoid all risk of failure from various causes, it will perhaps be better to be done in boxes and cover with a piece of glass. Guard against thick sowing, as I find they are very liable to damp off in the seedling stage; besides, they do not make the same sturdy plants as those sown thinly. When they are large enough to handle, they may be pricked out into a warm border, or, better still, into an old frame, where they will make nice plants for putting out in the spring.

Daffodils.—Where it is intended to divide and replant these, they should now be ready for lifting; indeed, sometimes this work is delayed much too long, as no sooner does the foliage die down than they commence to grow again. Lift the bulbs and select the largest and best for planting, while the small offsets are in many cases not worth troubling about. Store these in a cool, dry shed until they can be replanted, which work should not be unduly prolonged.

Syringas.—Like many other flowering shrubs, these have bloomed most profusely this season; in fact, I do not remember having seen a better display than we had this year. After flowering they should be well thinned out, cutting away all weak and exhausted wood and retaining only strong, healthy shoots. If this work has not been practised hitherto, it will be interesting to note the difference between those treated in this way and those left untouched.

Sweet Peas.—These will now be flowering freely, and to keep them in that state they will require almost daily attention. The old blooms should be cut off, and on no account allow seed-pods to develop, as the ripening of only a few would very soon put a stop to flowering. If liquid manure from the farmyard cannot be procured, give a slight dressing of some approved artificial manure. Afterwards give the plants a good soaking of water.

Plants Under Glass.

Salvia splendens.—Plants rooted fairly early will now be ready for shifting into their flowering pots, and as they are rather strong-growing subjects, the compost should be fairly rich. The size of the pot must be determined by the size of the plants and the use to which they are intended to be employed, but very good specimens can be had in 8-inch or 9-inch pots.

Caladium Argyrites.—As a decorative plant this little gem would be hard to beat in any collection, and yet it seems strange that it is not so much in evidence as it used to be. Although it is by no means difficult to cultivate, the trouble seems to be some neglect during the ripening period. Plants that were started early will now be losing their foliage, and should be dried off very gradually. Place them under the stage in the plant-house and water occasionally.

The Hardy Fruit Garden.

Gooseberries.—In order to prolong the season of this delicious fruit, and at the same time increase the size of the berries, give the bushes a good soaking of liquid manure. In gathering the fruit for preserving, thin out the berries of those varieties intended for late keeping, leaving only a moderate crop on each bush, and it is really surprising what good results can be had from this practice.

Newly Grafted Trees.—The binding should now be removed if this has not already been seen to, and the heads supported for a time, as, if left unprotected, serious damage may be done by strong winds and thunderstorms.

Fruits Under Glass.

Peaches.—Where the fruit has been gathered, the trees should be gone over and judiciously thinned, and the young fruiting wood fully exposed to the sun and light. Keep the foliage clean by syringing morning and evening, and give the border a good soaking. Later varieties should be kept moving, particularly Barrington and Bellegarde, as, if the season should prove cold and sunless, they never finish satisfactorily.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

ROSE GARDEN.

STOCKS FOR ROSES (*Cap Hayward*).—Most Rose-growers avoid using Sweet Briars as stocks, although we once knew of a grower who preferred them. We think we should try to have them exchanged for the ordinary *Rosa canina*.

ROSES WITH BLIND SHOOTS (*T. Ward*).—Some varieties have a tendency to produce blind or flowerless shoots, but often it is the fault of pruning, and frequently it results from damage caused by a very tiny black maggot. The best plan is to prune back the shoots to good plump eyes as soon as you are certain they are flowerless, and in your case you cannot do it too soon.

FRUIT GARDEN.

BLACK CURRANT LEAVES FOR INSPECTION (*Miss J. R.*).—The Currant appears to be attacked by the fungus *Gloeosporium Ribesii*. Spray, as soon as the fruit is picked, with sulphide of potassium, 1oz. to three gallons of water.

PEAR LEAVES FALLING (*W. F. M. C.*).—So far as we are able to see, there is no fungus present to account for the fall of the Pear leaves, and the appearance of the leaves suggests that the plant is placed where cold winds reach it. This variety is apt to suffer from cold winds, as it has long petioles, which enable the leaves to damage one another.

YOUNG FIGS GROWN IN POTS TURNING RED (*R. A. A.*).—Both the samples of fruit and foliage of the Figs sent are badly infested with red spider, and this, no doubt, is the cause of the trouble. Fumigate with Richards' XL All Insecticide until you get rid of them, and be on the look-out for them early next year, killing them before they do any mischief.

A CURIOUS NECTARINE (*Swansea*).—It is not quite certain what has caused the curiously irregular development of the Nectarine fruit you send, but cold may have done so. It is possible that puncturing by one of the leaf hoppers (insects allied to the Apple psylla and aphides) may have been the cause, or even aphides themselves. There appears to be no suspicion of fungus, disease, or bacterial trouble, such as gumming, on the fruit.

PEAR SCAB (*South Hants*).—The little Pears are attacked by the fungus *Fusicladium pyrinum*, which causes Pear scab disease and the cracking of the fruits. The trees should be sprayed immediately with Bordeaux mixture, at half the strength used for spraying Potatoes. The trees should be carefully pruned next winter, so as to remove all the shoots that show any sign of cracking of the bark or dying back, for it is in these shoots that the fungus passes the winter.

THE GOOSEBERRY RUST (*A. R.*).—The Gooseberry is attacked by the fungus *Puccinia pringshermiana*, the Gooseberry rust. This disease is not often very troublesome, and is not perennial in the bushes. Prompt removal and burning of all the affected leaves, fruits and shoots would probably partly or quite stop the disease. The fungus passes from the Gooseberry to the Sedge, on which it produces brown rust spots, and if it is desired to completely stamp out the disease, the most effective way would be to destroy all the Sedges in the neighbourhood.

CHERRIES FALLING (*Mrs. W.*).—The falling of the Cherries is not due in any way to lack of fertilisation, but probably to some interference with the water supply, although it may be the result of imperfect ripening of the wood last year. No doubt the splitting of the Nectarine stones and fruits is due to "gumming," a disease brought about by the attack of bacteria on vigorous growth. It would be well to cut out the branches showing gumming, and to paint the cut ends with white paint.

KITCHEN GARDEN.

CUCUMBERS UNDER GLASS (*X. Y. Z.*).—You do not say how old your plants are. If they are young and just coming into bearing, we should cut away the fruit on the main stem before it is full grown. But if the plants have been bearing some time, it does not matter. In Cucumber-growing the principle to go on is to stop each new shoot two leaves above the fruit, whether it is a

lateral or sublateral. Sometimes laterals (or new shoots) are blind and do not show fruit. These should be stopped at the fifth or sixth leaf, and most likely the second growth or sublateral will produce a fruit.

MISCELLANEOUS.

QUEEN WASPS (*Kircassock*).—Yes; all the wasps are queens. Drones and workers die in the late autumn or early winter, and only queens survive to start new colonies. Queen wasps have been remarkably abundant this year.

FORMALDEHYDE (*Quant. Suff.*).—The weakest solution of formaldehyde which may be expected to destroy green fly is 5 per cent. (1 part to 200 of water), but even that is likely to injure shoots and foliage of herbaceous plants. On the other hand, some plants, such as *Choisya* and other leathery-leaved plants, do not appear to be damaged even by a 2 per cent. solution.

ABOUT A BOWLING GREEN (*J. W. S.*).—It is not generally advisable to sow a bowling green with grass seed, far better results being secured by laying turf, which should be strong, composed of fine growing grasses and free from weeds. A green laid with such turf can be played on after a few months, but a green produced by sowing seeds ought not to be used for at least two years, for the grass under that time will not be vigorous enough to stand the hard wear. The grass can be improved by giving a dressing of bone-meal and soot at the present time; then, in autumn, sow 3lb. of basic slag and 1lb. of kainit to the rod. Do not apply a weed-killer while the grass is so young, but carefully hand-weed the green. For killing weeds upon paths it is advisable to procure a ready-mixed preparation from a seedsman. Several of such preparations are upon the market, all of which are good.

COLEUS AND PEACH LEAVES FOR INSPECTION (*Anxious*).—The Coleus is badly attacked by the root eelworm (*Heterodera radicola*). This pest attacks all sorts of greenhouse plants, and some outdoor ones as well. The soil in which plants attacked are growing should be burnt, the crocks destroyed, the pots thoroughly washed in boiling water, all soil from the potting-bench and the like being destroyed thoroughly. No precaution that can be taken should be omitted, for no pest is more troublesome to eradicate, and none is more destructive. Steam heating the compost intended to be used would be an additional valuable precautionary measure. The Peach leaves are attacked by the shot-hole fungus. The trees should be sprayed with ammoniacal copper carbonate, for which we have recently given a recipe.

NAMES OF PLANTS.—*Horace Inman*.—A variety of *Heuchera brizoides*.—*E. E. J., Clapham*.—1, *Lilium Martagon*; 2, *Campanula carpatica*; 3, *C. rhomboidalis*.—*Mrs. Sartorius*.—1, *Leptospermum scoparium*; 2, *L. flavescens*; 3, *L. myrsinoides*. *Cornus capitata* and *Vaccinium Myrtillus* also enclosed.—*Evinley*.—1, *Lonicera japonica halliana*; 2, *Silene alpestris*.—*C. P., Bournemouth*.—1, *Lonicera japonica halliana*; 2, *Buddleia variabilis*.—*Miss E. L., Cheshire*.—*Mentha Requienii* (Corsican Mint).—*Lielic*.—*Echium vulgare* (Viper's Bugloss).

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY'S SUMMER SHOW.

(Continued from last week.)

ROCK GARDENS AND ALPINES.

THERE were many beautiful summer-flowering alpine on view at this great show, but the rock gardens did not constitute so good a feature here as at the May show at Chelsea. Indeed, those in the open, for the most part suffering, no doubt, from the intense heat, appeared anything but happy, and, arranged largely in conjunction with canvas tents, had not the congenial environment which is so helpful at the other place named.

Taking them as we found them, we first came to a table group from Mr. Clarence Elliott, Stevenage, set up near the entrance. Here, indeed, there were no pretensions to rock-building, the aim obviously being to display good alpine plants effectively, and at the same time suggestively. That much accomplished, both the object of an exhibition and the aim of the exhibitor—the former from one point of view at least—are served. The finer plant groupings were those of *Campanula pusilla* Miss Willmott and *Erythraea Massonii*, the former providing a sheet of pale silvery blue, the latter just a carpet of rich rosy pink. Both were in great numbers, and, working shoulder to shoulder in the group, constituted a most enjoyable whole. Moreover, we revel in these picture-affording examples, which, while good in themselves, point the way to other things. These are not as a blaze of colour of which the eye quickly tires. One is rather drawn to them, and the more we see the fuller we realise their worth. *Campanula raddeana*, *C. pulla*, *C. G. F. Wilson* and other plants were here, too; but those first named dominated the whole by their presence and fine display.

Very near Mr. J. Wood, Boston Spa, had one of his characteristic rock gardens on a large scale in Yorkshire limestone. The rocks, their lie, and the beauty and informality of the whole, left nothing to be desired, and obviously the builder had closely studied this particular rock in Nature. It was not a towering, impossible thing; rather the reverse, one which amid happier environment

would have told effectively and, moreover, have suited a large number of plants. The planting, we thought, was less studiously done. There were faulty associations here and incongruities there, and we do not look for such where the fundamental part is so well accomplished. The miniature-growing Saxifrages, as, e.g., *cassia* and others, akin with the dwarfest of alpine Dianthi, are not fitting associates for the Himalayan *Meconopsis*, even if not in flower, or the Madeira Orchis (*O. foliosa*). Then, again, though this to some extent was unavoidable, the Ferns were in too hot and sunny a place, while the right-hand portion seemed as though all too hurriedly planted with border things, *Geum coccineum* and *Campanula persicifolia* in variety. A pretty rock pool, with Lillies and *Iris laevigata* grouped near, was quite good. There was also much good alpine planting.

In that from the Guildford Hardy Plant Nursery everything rested with the plants, of which *Erpetion reniforme*, *Wahlenbergia dalmatica*, *Oxalis enneaphylla*, *Hypericum empetrifolium* and Cobweb Houseleeks were among the best.

Close to this Messrs. Whitelegg and Page, Chislehurst, had a capital arrangement, using the Yorkshire stone, which alone is quite an ornament. The form, too, was distinct from any other. Notable plants were *Androsace lanuginosa*, *Hypericum Coris*, *Wahlenbergia vineæflora*, *Saxifraga Cotyledon pyramidalis*, which, with Creeping Thymes, *Campanulas*, Cobweb Houseleeks (*Semprevivums*), Dianthus and others made up a very pleasing whole. The Water Lily grouping at the end was very nicely done.

Messrs. Kent and Brydon, Darlington, had a rather mixed arrangement, using *Fagus Cunninghamii*, *Acantholimon glumaceum*, *Allium pedemontanum*, *Nertera depressa*, *Edelweiss* and *Hypericums* on a table space.

The Ightham Alpine Nursery, Sevenoaks, also had a small table with a variety of alpine associated with rock.

In the open, too, Mr. G. Reuthe, Keston, Kent, had a table arrangement, using a considerable variety of choice alpine and other plants. Some of the more uncommon included *Coris monspeliensis* (with bluish flowers), *Erodium Reichardii* (white), *Dryas octopetala*, the rare *Hypericum cuneatum*, *Saxifraga cochlearis*, *S. cassia*, *S. valdensis* and others, *Allium pedemontanum*, and the rare *Anemone nopsis caroliniana*, with white flowers. *Juniperus pachyphloea elegantissima* is notable for its distinct glaucous colour, while Heath, Genista, *Hypericum* and *Ononis fruticosa* each played a good part.

Quite in a spot alone, Mr. Reginald Prichard, West Moors, Wimborne, had a small stand full of choice bits of things. A set of the smaller-growing *Hypericums* at once arrested attention. For example, *H. cuneatum*, with small glaucous foliage, crimson buds and yellow blossoms on a plant of trailing habit, was charming; while such as *H. gracile*, *H. balearicum*, *H. empetrifolium* and *H. crenulatum* were all good and choice. *Campanula Scheuchzeri alba* is a particularly rare sort, and there are others of equal note.

Under canvas Messrs. J. Cheal and Sons, Crawley, had a fine piece of rockwork in Sussex sandstone in conjunction with terrace wall gardening, arranging and planting the whole with admirable skill. Good plant colonies were made up of *Primula capitata*, *Coronilla iberica*, *Erythraea diffusa*, *Campanula garganica*, *C. G. F. Wilson*, *Genista tinctoria* *Elatior*, and Cobweb Houseleeks. The arrangement was well supported by trellis and shrub.

Near by, Messrs. Piper and Sons, Bayswater, had a fine piece of combined rock and water garden, the former executed in excellent taste in Cheddar stone. The planting was remarkably well done, the plants blending with the grey of the rock quite naturally. Thymes, *Campanulas*, Cobweb Houseleeks, *Edraianthi*, *Edelweiss*, *Dianthi*, small shrubs and the like were all employed with good effect. In the water portion and around were Lillies, Japanese and other Irises, graceful Bamboos and other suitable plants. A beautifully designed piece of work throughout.

Mary Countess of Ilchester, Holland House, sent a large collection of *Semprevivums* and Saxifrages in specimen pans, the Cobweb section of the former constituting a very interesting lot. Of these alone there were about ten distinct forms, while the collection constituted a hundred or more.

The Burton Hardy Plant Nursery, Christchurch, had the pretty *Erodium corsicum*, *Primula littoniana*, *Saxifraga cassia*, *Sedum Liebmannii*, *Oxalis enneaphylla*, *Campanula excisa* and *Spigelia marylandica*.

In the alpine group from Mr. H. Hemsley, Crawley, we noted the very beautiful *Doryenium hirsutum*, a pink-flowered, woolly-leaved sub-shrub of a foot or more high belonging to the Leguminosae. It is a most charming plant. *Heeria elegans*, *Campanula pulla*, *Wahlenbergia vineæflora*, *Semprevivum tomentosum*, and *Erythraea diffusa*, a lovely bit of pink colour, were among other good things.

Messrs. R. Tucker and Sons, Oxford, had a small piece of rockwork on tabling, and here, too, some choice alpine were noted. A novelty was *Campanula mollis*, a trailer with rosy lilac flowers and woolly leaves, not very robust as shown. *C. Raineri hirsuta* is at once choice, dwarf and vigorous, an alpine calculated to do good and useful service. *C. excisa*, *C. Miss Willmott*, *Helianthemum tuberosum*, *Saxifraga squarrosa* and *S. mutata* were also noted.

Messrs. Bees, Liverpool, also had choice and new alpine, the outstanding novelty being *Hypericum Læve rubrum*, with flame red, golden-anthered flowers in terminal corymbs on bushes 15 inches high. It is a remarkable plant. *Lewisia Howelli*, *L. Cotyledon*, *Campanula Hostii alba*, *Rosecoea cautilifera*, *Primula pseudo-capitata*, *P. angustidens* and *Dianthus cæsius* Mantle were other good plants in a particularly choice lot.

HERBACEOUS PLANTS.

Mr. Maurice Prichard, Christchurch, Hants, was showing finely herbaceous and alpine plants in the large tent near the entrance. Delphiniums entered largely into the scheme, and there were also fine groupings of *Alstroemeria*, *Lychnis vespertina*, *Phloxes*, *Linolus* and other plants of the choicest description. Japanese Irises were also largely displayed, while many alpinas were found displaying their worth in the foreground. Perhaps one of the more imposing features in this exhibit was a grouping of *Lavatera Olbia*, a shrubby plant whose pink, Mallow-like flowers formed a great attraction.

Messrs. T. S. Ware, Limited, Feltham, exhibited a fine lot of hardy flowers generally, though more especially of Delphiniums, Gaillardias, Lupines, Astilbes, Eremuri and other such things. Alpines in variety, with which the whole group was surrounded, and moisture-loving Primulas, as *rosea*, *sikkimensis* and others, were freely grouped. *Tunica Saxifraga fl.-pl.*, double white, was also freely displayed.

A particularly fine display from Bakers', Wolverhampton, included a large gathering of English Irises, such as *Electric* (mauve), *Clio* (rich purple), *Mont Blanc* and *Jeanne d'Arc* being conspicuous in large groups. In addition, there was a capital lot of Delphiniums, together with other hardy flowers in season.

Messrs. Whitelegg and Page, Chislehurst, had a capital grouping of the more showy herbaceous flowers, Geums, Delphiniums, *Lychnis*, *Verbascums*, *Campanulas*, *Pentstemons* and others in formidable array demonstrating the wealth of hardy summer flowers.

Messrs. Godfrey and Son, Exmouth, had on view a fine lot of Canterbury Bells, particularly in rose, blue and white flowered sorts, the whole arranged in fine pyramids displaying these flowers at their fullest worth.

Messrs. Blackmore and Langdon, Bath, showed some very fine Delphiniums, notably such as *Yvette Guilbert*, *Lord Curzon* (a fine metallic blue with white eye), *Lieutenant Vassens* (mauve) and the pretty cross-bred forms of *D. Belladonna*, including *Mrs. Brunton* and *Moerheimi*.

Messrs. G. Stark and Sons, Great Ryburgh, in addition to a large assortment of Sweet Peas, had some fine spikes of *Kniphofias*, of which *Decorator* was the best. If these had not been forced into bloom they represent a valuable race, much earlier than the majority.

The Misses Hopkins, Shepperton-on-Thames, had a border group of herbaceous plants, followed by a small rockwork exhibit, both being suitably treated.

Messrs. Kelway and Son, Langport, had some very fine Delphiniums, such as *Knight of Langport* (purple, white bee centre), *Polar Star* (creamy or primrose), *Dusky Monarch* (of formidable stature), *Star of Langport* and *James William Kelway* (a very large flower, in purple colour with white eye, well framed on an imposing branched spike).

Messrs. Harkness and Son, Bedale, were responsible for a good grouping of Poppies, Eryngiums, Delphiniums, Lupines and *Verbascums*, the latter very handsome and imposing in their tall, stately spires. Of the more distinct we selected *Lady Allison* (gold), *Nance MacCormick* (rich yellow), *Willie Walker* (orange yellow)—a trio calculated to satisfy any in search of bold subjects suited to wild gardening or bold border work.

From Mr. J. L. Arkwright, Kinsham Court, Presteign, came a well-flowered group of plants of the so-called *Lychnis Arkwrightii*. In the interests of the general body of our readers we are bound to say that this is none other than *Lychnis haageana*, whether in stature, colour variation, form or anything else.

Mr. Vernon T. Hill, Langford, near Bristol, staged *Scabiosa caucasica* in variety, *Campanulas*, *Erigerons*, Delphiniums and, not least, the richly coloured *Gentiana Przewalskii*, which is not too frequently seen.

Messrs. Wells, Limited, Merstham, had some excellent Delphiniums, Gaillardias, Geums and other showy flowers. We were most struck, however, with *Delphinium Merstham Glory*, a very fine double mauve-coloured variety, having a densely furnished spike of flowers. *Le Danube* and *Rev. E. Lascelles* were also important in the group.

Messrs. Gunn and Sons, Olton, Warwick, had a grouping of herbaceous Phloxes in the best varieties, as *Sheriff*, *Ivory*, *Tapis Blanc*, *Elizabeth Campbell* and others of good repute, though not up to their usual exhibition standard of excellence.

In the group from Messrs. G. Gibson and Co., Leeming Bar, Poppies, Delphiniums, *Verbascums*, and *Scabiosa caucasica* in blue and white abounded, and there was also a good grouping of *Pimpinella magna rosea*, a pretty variety of a commonplace plant.

The Guildford Hardy Plant Nursery sent *Spiræas*, *Buddleias*, Gaillardias, *Campanulas*, Day Lilies, *Scabiosas*, *Iris Kämpferi*, Delphiniums and other showy flowers in abundance.

Messrs. W. and J. Brown, Peterborough and Stamford, had a fine grouping of Gaillardias, the more conspicuously beautiful and ornamental being *The King* (a grand crimson, tipped with gold) and *Lady Rolleston* (self yellow) among others. These two compel admiration. *Lilium szovitzianum*, *Eremurus Bungei* and *Ostrowskia magnifica* were all superbly displayed by this firm, the giant bells of the last named on stately, nearly 4-feet-high stems.

Mr. R. C. Notcutt, Woodbridge, had a fine show of *Iris aurea*, *I. laevigata*, Delphiniums, *Lilium Hansonii*, *Verbascums*, *Heucheras*, *Heleniums* and other good summer flowers.

Messrs. John Forbes, Hawick, Limited, had near the entrance a good collection of pot-grown *Pentstemons* and herbaceous Phloxes, both groups well displayed, in excellent condition and in some variety. Delphiniums and border Pinks and *Violas* were also on view.

Messrs. Frederick Smith and Co., Woodbridge, staged a particularly good lot of *Lavatera Olbia* (named in one or two collections *Malva Olbia*), together with *Pæonies*, Delphiniums, *Verbascums*, Gaillardias, *Potentillas*, *Heucheras*, *Scabiosa caucasica* and other flowers.

Messrs. George Bunyard and Co., Maidstone, had a really splendid group of herbaceous flowers, of which English Irises, Poppies, *Verbascums*, early Gladioli and Delphiniums were the chief. Of these latter, *D. Alake*, *Rev. E. Lascelles* and *Queen Mary* (iridescent blue with white eye) were very good. In addition, *Erigeron Edina*, with glittering white florets, is a plant of more than ordinary merit. *Gentiana dahlurica* and *Eremurus Bungei* were very good.

Messrs. Thomson and Charman, Bushey, had in a mixed grouping of flowering shrubs and herbaceous cut flowers examples of *Gentiana lutea*, of which a couple of the whorled inflorescences towered to nearly four feet high. *Verbascum Warley Rose* was also in this group, as was the interesting *Astrantia major*.

Messrs. Wallace and Co., Colchester, had a fine assortment of Delphiniums, Lilies, Eremuri and other noble hardy flowers, as *Iris Mon-aurea*. Of the Lilies, *Hansonii*, *davuricum luteum*, *szovitzianum* and *candidum* were the best; while of the Eremuri, *Shelford*, *Bungei* and *Olga* played their part uncommonly well.

Messrs. Lilley, Guernsey, had *Watsonias*, the graceful *Sparaxis* and early Gladioli in plenty.

Messrs. R. H. Bath, Limited, Wisbech, displayed a fine assortment of Irises, *Pyrethrums*, *Astilbes*, Eremuri, and Delphiniums.

ROSES.

The Queen of Flowers was wonderfully well represented, but the extremely high temperature was sorely trying to the cut blooms. Taken as a whole, the exhibits were quite up to the usual standard, but outstanding novelties were not particularly numerous.

In the big tent Messrs. William Paul and Sons, Waltham Cross, and Messrs. G. Paul and Son, Cheshunt, occupied their usual corner positions. The first named had a most brilliant display, consisting of tall pillar and weeping varieties. Among these *Hiawatha*, *Excelsa* and *Tausend-schön* were very prominent. Beneath were arranged well-filled baskets, each containing a separate variety, notable among which were *Rayon d'Or*, *Ophelia*, *Lady Downe*, *Mrs. C. E. Pearson*, *Prince de Bulgarie*, *Lyon* and several seedlings of promise, the whole making a most brilliant show.

Messrs. G. Paul and Son featured a similar exhibit, *American Pillar* and *Dorothy Perkins* being prominent among the ramblers. Dwarf Polyantha varieties were well shown, while baskets of all the most popular varieties, such as *Mme. Melanie Soupert*, *Rayon d'Or*, *Comtesse de Saxe*, &c., were superbly shown.

Messrs. Hobbies, Limited, Dereham, set up a most effective collection on the tables, the background being filled in with tall weeping varieties, while pillars and vases of cut blooms were set out in the foreground. *Pink Pearl*, *Lyon*, *Lemon Pillar*, *Effective*, *Rayon d'Or* and numerous others were noted in good form.

Messrs. J. Jeffries and Son, Cirencester, made a very effective display on the ground. Tall pillars and weeping standards were a feature, while beneath were arranged baskets and tall vases containing fine examples of *Rayon d'Or*, *Chateau de Clos Vougeot*, *Prince de Bulgarie*, &c.

Mr. G. Prince, Oxford, had a wonderfully bright stand, and here big masses of *Josephine Nicholson* (a fine new salmon), *Rayon d'Or*, *Mrs. Aaron Ward*, *Lady Pirrie*, *Mrs. A. Tate*, &c., were most effectively set up.

Messrs. W. and J. Brown, Peterborough, invariably show well, and on this occasion they exhibited some brilliant flowers in all the leading varieties, including *Marquise de Sinety*, *Melanie Soupert*, *Leslie Holland* and the brilliant and sweet-scented *Effective*.

Mr. Elisha J. Hicks, Twyford, featured his beautiful crimson single, *Princess Mary*, together with *Mrs. George Norwood*, *Mrs. Charles Reed*, *Comtesse du Cayla*, *Leontine Gervaise*, *Rayon d'Or* and *Lyon*.

Messrs. B. R. Cant and Sons, Colchester, made a great feature of the new and magnificent red, *Auguste Hartmann*. *Mrs. R. E. Grosvenor* was also well shown, while a great number of all the leading favourites were brilliantly displayed.

Practically all recent novelties were staged by Messrs. Alex. Dickson and Son, Newtownards, and right well did the firm acquit itself. *Queen Mary*, *Red-Letter Day*, *Mabel Drew*, *H. V. Machin*, *Janet* and *Lady Plymouth* were a few of the varieties noted.

Messrs. Hugh Dickson and Co., Limited, Belfast, despite the long and trying journey, succeeded in showing a number of new varieties in good form. *Ethereal* (an improved *Simplicity*), *Oriflame*, *Ulster Standard*, *Radiant Morn* and others were effectively displayed.

Messrs. G. Bunyard and Co., Maidstone, put up a small but bright collection.

Mr. W. Easlea, Eastwood, managed to get almost every variety worth growing on the small space allotted him. *Rayon d'Or*, *Melanie Soupert*, *Leslie Holland*, the new *Cherry Page*, *A. R. Goodwin* and *Lady Hillingdon* were a few that caught the eye.

Messrs. Jarman and Co., Chard, had some magnificent boxes containing blooms of full exhibition quality. The eighteen blooms of *Juliet* in one box were the best we have seen this season.

Messrs. Frank Cant and Co., Colchester, set up a very pleasing exhibit, the new climber, *Braiswick Beauty*, standing out prominently. *Cupid*, *Beaulah* and *Mona O'Neil* were other taking features.

Messrs. George Jackman and Sons, Woking, had a great number of varieties on view.

Messrs. H. Lane and Son, Berkhamsted, also displayed a bright little collection.

A very good ground group was arranged by Mr. R. C. Notcutt, Woodbridge, and here *Mme. E. Herriot* shone in all her glory.

One of the best displays was that of Messrs. Stuart Low and Co., Bush Hill Park. Nothing later than 1913 varieties were shown, unless one classes the American *Mrs. Charles Russell* as a 1914 novelty; but each variety was in great form and shown in quantity. Some of the most prominent were *Mrs. Charles Russell* (a very fine pink), *Rayon d'Or*, *Chateau de Clos Vougeot*, *British Queen*, *Miss Alice de Rothschild* and *Lady Pirrie*.

Messrs. Morse Brothers, Woodbridge, staged some excellent flowers; while in the big tent Mr. Charles Turner, Slough, set up a fine group of rambler and other varieties. Some bright bits of colour were noted in this group.

The Rev. J. H. Pemberton, Havering, made a little display with seedling *Roses*, *Danée*, *Winter Cheer*, *Moonlight*, *Galatea* and *White Rambler* among them. All are of the same rambler type.

SWEET PEAS.

A capital lot of blooms, was set up by Robert Sydenham, Limited, Birmingham, and the founder's namesake was in great form. Other superb varieties were *King White*, *Princess Mary*, *Thomas Stevenson*, *Maud Holmes*, *Barbara*, and *Lady Evelyn Eyre*.

A superb exhibit was staged by Sir Randolph Baker, Bart. (gardener, Mr. E. Usher), and the strength of his flowers suggests a warm time at the coming shows. *Edith Taylor*, *King Manoel*, *Constance Hinton*, *Thomas Stevenson*, *Edna May*, *Hercules*, *James Box* and *Lady Evelyn Eyre* were simply immense. The flowers were set up in vases and upon tall pillars, the whole making a most effective stand.

Messrs. S. Bide and Sons, Farnham, staged all the most popular varieties and several telling novelties, including *Phyllis Bide*, a fine deep orange, set up in effective fashion.

Messrs. Gilbert and Son, Dyke, Bourne, Lincs, displayed some very good blooms, together with *Liliums*; as did Messrs. Jarman and Co., Chard.

CARNATIONS.

Messrs. William Cutbush and Sons had some very nice Carnations and a few Pinks in pots. These were grouped in company with *Polyantha Roses*, *Cannas* and *Palms* into an effective mass. Among the Carnations we thought *Lady Coventry*, *Mercia* and *The Queen* three very taking varieties.

Mr. Charles Turner had some three hundred plants of good standard varieties of *Malmaisons*, including *Mrs. Trelawny* (salmon pink), *Lady Middleton* (flaked pink), *Thora* (pale blush), *Maggie Hodgson* (Old Clove colour and very sweet), *Irene* (deep blush) and *Princess of Wales* (pink). These were surrounded with *Polyantha Roses* of various kinds, mixed with *Nephrolepis todeoides*, *Adiantum cuneatum* and other Ferns.

Messrs. Young and Co., of Cheltenham had one of their usual fine displays. Five large stands were prominent at the back of the group, with smaller vases and bunches in front. *Lady Henderson* is a strong-stemmed, vigorous-growing warm pink, and was shown in quantity for the first time. The Hon. John Boscawen (medium pink) is another new variety, and so is *Lady Greenall*, which is one of those colours which are difficult to determine, but which might not inappropriately be compared to claret and lemonade.

Messrs. Stuart Low and Co. had a group of *Cleopatra*, which, now we are reminded of beverages by the heat, we think is not unlike good old port in colour. This was flanked on either side by paler tints, such as the pink *Princess of Wales* and the lovely rose *Gorgeous*, which is quite the ideal colour for table decoration under artificial light. Other good things were *Ceres* (a perpetual *Malmaison* of the colour of *Enchantress*) and *Venus* (a white with an occasional trace of carmine in some of the petals); so far from taking from its beauty, these flecks do for *Venus* what patches did for our great-grandmothers.

Mr. James Douglas as usual had his superb border varieties. *Gordon Douglas* was shown under name for the first time. It is a light bright crimson of perfect form, with strong stems and a delightful Clove scent. The *Ameer* is its counterpart in a deeper shade, but not quite so sweet-smelling. *Daisy Walker* is a flower of quite a different type. It is a white-ground, lightly flaked *Picotée*, the few stripes of colour being of a bright cerise.

Mr. A. F. Dutton had grand baskets of *Mikado*, *May Day* and the pretty deep pink *Mrs. A. F. Dutton*.

Mr. C. Engelmann staged on the ground. In a prominent position was a column of a grand rose called *Pioneer*. On either side were smaller masses of *White Pioneur*, *White Enchantress*, *Lady Northcliffe* and *Beacon*. The bottom of the group had good examples of *Lucy* (deep salmon pink), *Sunstar* (yellow, with small red splashes), *Scarlet Carola* (a sport from the old clove *Carola*), *Mrs. Raphael* (red) and *Marmion* (Painted Lady type).

SUNDRIES.

"Ubel" sprayers and syringes were prominent, and the lime-washing machines, so useful for shading during the hot weather, were special lines shown by the United Brassfounders Company, Cranbrook, Manchester.

AWARDS.

SPECIAL CUPS.

Coronation Cup, for the best exhibit in the show: Messrs. Wallace and Co., Colchester, for a water garden and Japanese Iris.

The Wigan Cup for *Roses*: Mr. E. J. Hicks, Twyford, Berks.

The Clay Challenge Cup, for a *Rose*, not in commerce, possessing the true old *Rose* scent: Messrs. William Paul and Son, Waltham Cross, for *Rose Queen of Fragrance*.

THE GARDEN.

No. 2226.—VOL. LXXVIII.

JULY 18, 1914.

NOTES OF THE WEEK.

Pentstemon Douglasii in the Rockery.—This striking, shrub-like plant, with its pale blue or lavender flowers, has been very fine this season; indeed, it seems surprising that so few of these plants are to be found in the rockery or wall garden. They bloom continuously over a long period, so much so, indeed, that they generally make very little growth. Cutting off a flower-spike induces them to produce cuttings freely, which may be taken off now and rooted under a handlight. They should make nice plants by the spring.

A Pleasing Combination.—We were interested the other day to find a good group of the beautiful *Campanula persicifolia humosa*, a charming pale blue, semi-double form of the well-known Peach-leaved Bellflower, among which *Silene Armeria* had been sown in the spring. The pleasing pink of the *Silene* made an excellent groundwork for the tall spikes of the *Campanula*.

The Deodar Producing Cones.—From the fact that the tree seldom produces cones in this country, it is worth recording that a tree by the side of the Broad Walk at Kew is maturing a number of cones this year. A native of the Himalayas, *Cedrus Deodara* was first introduced to Britain in 1831. With age the trees assume the familiar flat top of the Cedar of Lebanon. Why the Atlas Cedar (*Cedrus atlantica*), though not introduced until ten or twelve years later, should produce cones in abundance and the Deodar rarely, seems difficult to understand, unless it is because the Himalayan tree is less hardy.

Dianthus gracilis.—What *Viola gracilis* is to the mountain Violas, *Dianthus gracilis* is to the rock garden *Dianthi*. It is the daintiest, most informal and the most exquisitely coloured of any *Dianthus* it has been our pleasure to meet. We grow a good range of *Dianthus* species and hybrids, but there is nothing among them to equal the delicate beauty of *gracilis*. The leaves and stems are very glaucous, and the flowers are of a brilliant rosy pink shade (a pink without magenta). The flower-stems are branching, and the tiny blossoms are beautifully poised at the tips. The petals are delightfully irregular, with nothing of the exactness of the majority of *Dianthi*, and in this and its extreme delicacy of form lie its wonderful charm.

Yellow Foxgloves.—The old order of yellow Foxgloves is passing, giving way to the new. The old-fashioned *Digitalis ambigua* and its allies were at the best only curiosities in the garden, but the new yellow forms, raised from the improved strains of our charming native *D. purpurea*, are both of great decorative beauty and of sterling service to the garden generally. To one who loves the white, pink and rose hued Foxgloves, the new

flowers as they bloom, and drying them well. To these allow 1lb. bay salt, 2oz. saltpetre, one Nutmeg, half an ounce of Cloves and half an ounce of Allspice. Next add 1oz. of Bergamot and 6oz. powdered Orris Root. Allow next one drachm each of spirits of Lavender and essence of Musk and Lemon. Mix all the ingredients together, put them into a deep china bowl or jar, add the dried petals and mix them very often."

Staking Pentstemons.—The staking of the taller-growing varieties should be attended to without delay. Such varieties as Mrs. John Forbes, Negress and George Holmes will in many cases grow over three feet in height, and, if once allowed to fall over, they never give the same results.

A Good Pink Bedding Rose.—One of the best bedding Roses of comparatively recent introduction is Miss Cynthia Forde. As will be seen in the illustration, it makes a shapely spreading bush and produces its flowers in profusion. These are a pleasing shade of soft pink, something after the tint found in Gustav Grunerwald, but the shape of the flowers is quite different. The petals fold over each other very neatly, but the blooms are rather flat. They are fragrant, though this desirable feature is not so pronounced as in some Roses. The foliage is always neat, smooth and good, and resists mildew as well as that of any Rose we know. The bush illustrated was planted two years ago last February, and is now about three feet high.

Sweet-Scented Pinks.—The Pink is an old denizen of British gardens, and it should be one of the sweetest. Association seems to demand this. We have been led to make the above trite remarks by a visit we paid to a skeleton garden at Uppingham last June. It had been a green hillside twelve months before, so to clothe its

ROSE MISS CYNTHIA FORDE, A PINK-FLOWERED VARIETY FOR BEDDING.

yellow will come as a pleasant surprise, and, with a little improvement and due selection of the best forms, we venture to say that in a few years they will attain an immense popularity.

Recipe for Pot-Pourri.—At the request of several readers we publish an old recipe for the making of pot-pourri: "Allow six handfuls of mixed Rose petals, add to these three handfuls of Orange Flowers, Carnations and Clove Pinks, also of other sweet-smelling flowers two handfuls, adding the

nakedness a large quantity of the real old-fashioned small double white Pink had been planted literally all over it. It was a warm day, which no doubt helped to bring out the perfume. The gratifying fragrance of that garden will remain in our memory. As far as we are aware, none of the larger and newer varieties, like Mrs. Sinkins or Her Majesty, are as sweet. Hence this is a plea for the more extensive use of the small old double Pink in gardens.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Sweet-Smelling Rosaries.—Mrs. Gore's "The Rose Fancier's Manual," 1838, page 79, has the following: "The *Pastilles du Serail*, sold in France as Turkish, in rosaries and other ornaments, are made of the petals of the Belgian or Puteaux Rose, ground to powder and formed into a paste by means of liquid gum. Ivory-black is mixed with the gum to produce a black colour; and cinnabar or vermillion, to render the paste either red or brown. It may be modelled by hand, or in a mould; and when dried in the sun, or a moderate oven, attains sufficient hardness to be mounted in gold or silver." Rosa Gallica would probably be better than the Belgian, since the former gains in scent on drying, while the latter loses scent. Rose water might be used to melt the gum, or a drop of otto of Roses might be added to the soft mass.—BARROW THORP.

Wasps' Nest on Rhododendron.—I enclose a photograph of a wasps' nest that I destroyed with cyanide of potassium on June 22. You will notice that it was built on the top of a Rhododendron bush about six feet from the ground. The small point projecting at the bottom of the nest is where the creatures were going in and out. I thought it was worth sending to you if you care to reproduce it in your paper for the benefit of your readers. I might add I always dissolve the cyanide of potassium in hot water and cork it tightly in a bottle; then tie some cotton-wool on the end of a Bamboo cane and well soak the wool before putting it in the nest. I find it is more economical than using the cyanide dry, and quite as effectual.—GEORGE GUMBRELL, *The Garden*, Rose Mount, Ascot.

WASPS' NEST BUILT ON THE UPPER PART OF A RHODODENDRON SHOOT.

also lately added prizes for queen wasps. In this village alone the competitors accounted for 2,382 queens.—E. M., *Swanmore*.

Rose American Pillar, and Some Others.—A note to confirm your opinion (page 337, issue July 4) of this fine Rose. At the present time it is at its best with me, and out of a run of 300 feet of garden fencing that I am glad to say is entirely covered with rambling Roses, American Pillar for general effectiveness is *facile princeps*. Its enormous clusters and fine flowers that do not fade in the hottest sun, fine growth and foliage, all make it stand out. Minnehaha is still the best pink, much to be preferred to Dorothy Perkins; Lady Godiva, the best of all the Dorothy Perkins sports; Shower of Gold, the best yellow; but Goldfinch was magnificent three weeks ago. Excelsa, the best crimson, is more effective than Hiawatha; Tausendschön, now over, but quite indispensable; François Juranville and Miss Helyett, the latter very early, but very fine large flowers, resembling

the cup was offered. I should not have worried you with this communication were it not that I found a good number of others of my opinion. I may add that I am not interested in the most remote degree with either of the firms in question; but had I been judging, I should certainly have placed the prophet before the apostle on this occasion.—OLD ROSE. [We have ascertained that our correspondent has no financial or other interest in Mr. Hicks, and, in fact, does not even know him. We publish his letter, as the point was one that we heard freely discussed at the show, and we are holding over further correspondence on this subject until the publication of our next issue.—ED.]

Groups at Holland House Show.—In your report of Holland House Show, you mention that Messrs. W. Wells and Co., Limited, were exhibiting Gaillardias and Delphiniums. This is not the case, as I have taken over the whole of the hardy plant department.—W. WELLS, JUN., *Hardy Plant Nurseries*, Merstham, Surrey.

Naming of Daffodils.—"What's in a name? A Rose by any other name would smell as sweet." That is all very well if one wishes merely to gratify the nose, but I take it neither Juliet nor the immortal William was a gardener or horticulturist, or the question would not have been asked. I think it is worth a little trouble to select an attractive name for a new variety of merit, for it may make a difference in its reception by the public, especially where they have only catalogue description to go on. I have noticed in recent catalogues, &c., certain names that are not attractive, and I feel inclined to enter a mild protest against the labelling (or libelling) of the Narcissus of classical origin and graceful, stately outline with such uncouth appellations. Without an interpretation, a grotesque name like Mowgli does not appear to have much to commend it, while Swashbuckler, Rags and Tatters, Bulldog, Whelp, &c., though possibly they may be appropriate, do not convey to me a favourable impression, but straightway prejudice me against the bearers of such unprepossessing names. I know it is not easy to find taking names for all the

new Daffodils coming forward each year; for one reason, so many good names have been used up on inferior things which have not come to stay; still, I venture to think we need not yet dub our favourites with unattractive cognomens. English personal names and titles are fortunately not so unwieldy as Continental ones, and are freely resorted to; but even in this line it seems to me somewhat weak to name Roses, Dahlias, Sweet Peas, Carnations, Daffodils, Chrysanthemums, &c., in turn after the same person. I like to see names reasonably short and euphonious, characteristic, as far as may be, of the subject, of good or refined origin or associations, or with some other feature likely to arrest attention or connect the name with the particular flower. I do not know the procedure for registering new varieties in the Royal Horticultural Society's Classification; but do you not think the society might exercise some censorship, and make an effort to preclude ugly names from the list, which contains remarkably few to which exception may reasonably be taken? —A. E. G., *Auckland, New Zealand*.

that good Rose Lady Waterlow in the bud and that fine Tea Mme. Antoine Mari when fully out. The only scarlet wichuraiana is Diabolo. This is quite good, and the flowers keep their colour; it can be strongly recommended. We still want a good white. My White Dorothy is very good, but it will come pinkish at times, which rather spoils it. Crépuscule, a Rose of French origin, of delightful pink and orange colouring, carried hundreds, possibly thousands, of its pretty blooms in early June. Evangeline, a tremendous grower, is very sweet, although its flowers are fleeting and single. Pink Pearl is very pretty as a pillar.—HERBERT E. MOLYNEUX.

The Most Fragrant Rose.—I went round the tents rather early at the Holland House Show, and at that hour a Rose (I forget its name) shown by Messrs. Paul was labelled as having won the cup presented by Messrs. Clay. I do not know whether this award was subsequently confirmed, but I hope not, as, in my opinion, the Rose Mrs. George Norwood, shown by Mr. Elisha Hicks, complied better with the conditions under which

School Flower Shows.—In reference to the recent correspondence on this subject, for years I have done much to encourage the holding of shows in villages for the benefit and instruction of the children. The Bishop's Waltham Horticultural Society long ago established branches in several villages in its area, holding exhibitions in June each year for cut, wild and other flowers, and their arrangement in vases, baskets, table decoration and so forth. These shows are held with a view to encouraging and teaching the children how to arrange a simple posy or basket of wild and garden flowers in an appreciative manner, so that they may be all the better able to brighten their homes with flowers which in the country are so plentiful. We find, too, what a vast improvement is made, even after a couple of years' tuition, especially in the blending of colours. The society provides vases all alike, so that the children start on the same basis. Baskets and tables are also found by the society, and the prizes are useful, which is a distinct encouragement to the youthful competitors. To enable the scholars to become better versed in the names of our native trees and shrubs, as well as many others growing in the country, prizes are offered for the best collection of twigs of trees and shrubs correctly named. We have

A Hardy Pear for the North.—Happening to look over a back number of *THE GARDEN* (June 13), my eye has fallen on an enquiry by "H. H. A., Glasgow," for a good recent variety of Pear to suit that district. Let me suggest to him to try a tree or two of Doyenné du Comice, one of the very best in size and flavour, and which, to my surprise, I find also one of the hardiest. In the garden here, though subject to much hoar-frost in spring, and not in a Pear soil, it blooms and sets and ripens with more certainty than any of the older and local varieties, and this without any protection whatever, at any season. It is, however, on a wall facing south. I doubt whether it would ripen in any other aspect.—K., *Fife*.

Lightness in Table Decorations.—I have recently received a schedule of a well-known Yorkshire horticultural society. It contains a section entitled "Hints to Exhibitors," part of which is devoted to table decoration. The gentleman who is giving these hints says with regard to table decoration "that it is a mistaken idea that everything used should be as light and flimsy as possible. . . . I should never think of decorating a table with Sweet Peas and Gypsophila elegans." He then goes on to recommend Roses alone. What is the opinion of your readers on this subject? I myself am an exhibitor, and have met with some success in this class; but to my mind Sweet Peas and Gypsophila elegans are ideal subjects for table decoration. Also, I think that table decorations *should* be as light as possible, so as not to obstruct the vision of the persons sitting at the table.—H. A. ELLIOTT.

Roses on Their Own Roots.—I see in June 27 issue of *THE GARDEN* a note from a reader, signed "E. M.," on Roses on their own roots. I may say that I think many of the climbers do exceedingly well on their own roots. I have annually rooted cuttings now for upwards of fifteen years, and find that if taken at the right time (either late September or early October) and planted in a suitable position, not many varieties will fail to strike. If left in the cutting-beds for the following season, not many varieties fail to do well, and especially the climbers. I have now in full bloom several large bushes of that lovely climber, Goldfinch, and I think they look even better than the parent plant. I also find that Lady Ashtown, Mme. Abel Chatenay, Irish Elegance and many other fine Hybrid Teas, also the Polyanthas, such as Cecile Brunner and Perle d'Or, do well on their own roots.—T. R.

Anent this subject, raised by "E. M." in June 27 issue of *THE GARDEN*, page 326, I offer a few words of my experience dealing with dwarf and pillar varieties over a number of years. No weak or delicate growers of either section of Roses should be dealt with unless they can be treated more generously both as regards soil and position than is customary, and even then it is questionable if they would prove as satisfactory as budded or grafted plants. On the other hand, vigorous growers do remarkably well from cuttings for a number of years—long enough, I think, to justify the method and time spent—though I willingly admit the probability that budded specimens would prove the stayers eventually. The variety that has done best here is Caroline Testout, and perhaps a little later on I may be able to forward a photograph showing a bed of own-root Roses in flower. Others that have done well are Frau Karl Druschki, Mme. Ravary, Mme. A. Chatenay, and Mme. Edmée Metz. Among climbing varieties,

Dorothy Perkins, Crimson Rambler, Conrad F. Meyer and Tea Rambler have done splendidly, also Grüss an Teplitz as a bush.—C. T., *Highgate*.

Ozothamnus rosmarinifolius.—The effect given by using this beautiful shrub as dot plants and for heightening the back of a rock garden is well illustrated in the rock garden here, where we have been successful in growing it without much difficulty for a number of years. The flowers, which are open now, are similar to some of the Spiræas and of a pleasing white, and add considerably to the floral effect produced by the many Rock and Sun Roses, Campanulas and Sedums flowering at the same time. Unfortunately, it is not sufficiently hardy to withstand a severe winter; consequently, a position which is sheltered from the north and east is advisable. Apparently it is a shrub which will grow in almost any soil, but I notice a considerable difference where the soil is enriched by leaf-mould and sand. Its habit and appearance is much like the ordinary Lavender; but pinching of the main shoots is necessary in the spring to get a well-shaped bush. A native of Australia, it is not very common in England, but well worth growing.—GEORGE BURROWS, *Shendish Gardens, King's Langley*.

White Ointment Roses.—Although Rosa alba was considered to be "drying, binding and cooling," it was little used in medicine except for diseases of the eyes, and for this purpose chiefly the distilled water, but also occasionally in the form of a cataplasm or a powder. The old Ointment of Roses was made of Gallica Roses (the red Rose), although de L'Obel in his "Animadversiones" on Rondelet, 1605, says that if the juice of white Roses is used to make this ointment and a little alum added, a fine (*per eleganti*) yellow colour is produced. This juice and alum was also used by painters. "The Grete Herbal," 1527, under the heading (R)osa, says that "They that have a pale/wane/whytysshe or blacke colour ought not to be put in medycyne." The nearest ointment at the present day in the British Pharmacopœia is the Unguentum Aquæ Rosæ, commonly known as cold cream. There are still some dozen or so preparations containing Roses in the Pharmacopœia. "Salmon's Herbal" gives fifty-one preparations of Roses, and this, of course, does not include many well-known preparations into which the Rose entered as a minor ingredient. By the way, the erudite composer of the last acrostics which appeared in *THE GARDEN* stated that William Salmon was Physician to Queen Anne. Now Salmon was capable of "spatch-cocking" a prayer into one of his popular medical works thanking Heaven for making him so clever, good and kind, and obviously just the very physician required by his readers, and he would have been quite incapable of leaving us in doubt had he been Physician to the Queen. "Anne Amateur" gave a charming recipe for ointment of white Roses in *THE GARDEN* of August 9, 1913, and also a partial description of an ointment pipkin. Could you persuade her to let us have a sketch or a photograph of the pipkin?—BARROW THORP. [We would be glad to have a photograph.—ED.]

FORTHCOMING EVENTS.

July 21.—Southampton Show (two days).

July 22. — Flower Shows at Leamington (two days), Hayward's Heath, Preston (two days); Cardiff (two days), and Yorkshire Agricultural Show at Bradford (three days).

PLANNING AND PLANTING THE LITTLE GARDEN.

OUR competition for the best designs for planning and planting the little garden has created world-wide interest, and applications for the site plans have been received from nearly every part of the world. There is still time for new readers to enter, as the completed plans need not reach this office until September 1. For the benefit of those who may not be acquainted with our competition, we may briefly state that we are offering cash prizes to a total value of £33 12s. and a number of book prizes for the best designs. Those who have not seen the rules and conditions governing this competition may secure them by applying to the Editor of *THE GARDEN*, 20, Tavistock Street, Covent Garden, London, W.C., and enclosing 1d. in stamps to cover the cost of postage. The coupon this week appears on page vii.

THINNING APPLES.

[In Answer to a Correspondent.]

OUR correspondent says, "Could you tell me the proper way to thin Apples? I have never known Apples to set like they have done this year. Bunches of five, six and seven all over the tree are quite the rule, and they all seem equally vigorous."

Those readers of *THE GARDEN* whose crops of Apples have been destroyed by recent heavy frosts may be excused if the reading of the above statement causes their mouths to water. Happy "Devon," to be immune from such tragedies? There is always a reluctance on the part of amateurs (and, we are afraid, on the part of many gardeners as well) to sufficiently thin their fruit crops, no matter what kind of fruit it may be. As for the reason or cause for this, we will not now stay to enquire. But we may be allowed to point out the loss and injury caused to the fruit and to the trees by not attending to this important work in good time. Take our correspondent's Apple trees. Supposing he does not thin his crop, what will be the result, say, as regards the money value of the crop when the fruit is ripe? The fruit will simply be half developed, stunted, juiceless and tasteless, and in the market would scarcely fetch the cost of carriage; and what about the poor tree, half starved by the burden it had to carry? Trees cannot speak. If this one could, we dread to think of the quality of its language! Instead it sickens and refuses to bear a similar infliction for at least two or three years. Where does the wisdom of our cropping come in? Reverse the conditions. Let our correspondent reduce the number of Apples to, say, two of the best in each bunch, including the crown fruit in each case. Possibly he will lose something in the weight of crop, but the quality, which, after all, in fruit is everything (especially if grown for consumption at home), would be perfect as compared to the others, and the price, if sold, would be top price. It is the same with all fruit. Take the Peach or the Nectarine. If you want to destroy the rich quality of its flesh and the delicious sweetness of its flavour, overcrop your trees, and you are bound to do it. Lesson: Undercrop all fruits in preference to incurring the danger of overcropping.

JULY NOTES ON CARNATIONS.

SINCE last writing, instances have been brought to my notice of border Carnations proving intractable in certain soils which produce vegetables, fruits and flowers in general, especially Roses, of a quality leaving nothing to be desired. Soil is not everything, by any means, position having a very real predisposing effect, and, provided we have young, healthy plants and an airy position, it should be possible to manipulate soil of any nature to meet their requirements. In pot culture it is evident that anything from peat to a clayey loam will yield results more or less satisfactory; hence the object, where there is a difficulty in their outdoor cultivation, is to endeavour to provide a proper rooting medium.

Early versus Late Layering.—Of probably more importance than soil and climate is the condition of the young stock. It is quite obvious

needed strength in spring, and so struggles through the summer a miserable object; and it is worth remarking that all the old writers on the Carnation favoured early propagation, some in June, none later than July; only it must be remembered that early rooting must be followed by early transplantation, as, directly the roots are advanced enough to admit of it being effected without a check to growth, every day that elapses beyond that renders the layer less valuable as a plant. In heavy soils, in which root action is concentrated within a lesser circumference, the effects are less noticeable than in light soils, through which roots elongate in all directions.

The Operation of Layering is very simple, much more so than it is often supposed, and there are varieties which root with so much facility that merely notching the stem, and keeping the part notched close to the soil by means of a stone to steady it, is followed by the production of roots. In gardening it is not always wise to use such simple means, and the old-fashioned split stem should be adopted. With many soils, again,

keep several layering. Personally, I never remove any leaves unless they are diseased. The fixing of the layers is undoubtedly the crux of the operation, and clumsy workmen will frequently destroy more by breaking than they preserve. A lengthy layer can be made secure of fracture by twisting it, and one too short to twist, when pressed back and slightly elevated while the process of placing it in the soil is being performed, will not snap off the parent plant.

The tongues of layers sometimes curl up, and so, being raised above the surface, never root. This is prevented by fixing the usual peg so that it embraces the tongue of the layer as well as the part necessary to hold it down. The peg suitable for this purpose is made like a hairpin and not hooked. Hairpins are suitable, also pieces of Snowberry and Bracken, doubled, where these are to be had. Pieces of Willow may also be used, but these are apt to root, while strips of Bamboo or cane will be found equally suitable.

I will only indicate another item in the economy of propagation, viz., do not insert the tongue deep in the soil. If a quarter of an inch above the slit be covered with soil, as well as the tongue, that is ample, and, with an occasional application of water in dry weather, rooting will be more successful than if the tongue were inserted to a greater depth.

R. P. BROTHERSTON.

A SPRAY OF THE AMERICAN FRINGE TREE CHIONANTHUS VIRGINICA.

that the propagation of border varieties is frequently belated beyond reasonable limits. Like other plants, the Carnation, for propagating, has a special period when roots are emitted in a brief time and produced with great abundance. It never happens that this period is forestalled, too late layering being the mistake. Now it is clear that a slow-rooting and, at that, sparsely rooted layer at the period when growth terminates for the year is in the very worst condition not only to winter safely, but it never acquires

it is not essential to introduce a compost as a means to induce root action, but here again it is a small matter, and if anyone cherishes a fear about it, certainly use a light compost. Only—and it is a very special “only”—see that the material is arranged so that the layer roots into it, and not, as I have very frequently seen, placed so that the layer is quite altogether underneath it. The slitting of the stem is a simple operation, and where there is a large number of layers to operate, one man should be employed. A clever hand will easily

while those of *C. virginica* push out near the ends of last season's shoots below the new growths. The petals of *C. retusus* are shorter and the inflorescence more erect. The Chionanthuses belong to the Natural Order Oleaceæ. They thrive in loamy soil and are best propagated from seeds, which can be readily obtained from America. The Chinese species can be grafted on *C. virginica*, or it may be layered, as also can good forms of *C. virginica*, of which there appear to be several.

A. O.

THE FRINGE TREE.

(CHIONANTHUS VIRGINICA.)

IN common with numerous other deciduous shrubs, *Chionanthus virginica* has flowered this year more freely than is usual in this country. A native of the Eastern United States, the American Fringe Tree was first introduced in the eighteenth century to British gardens. It forms a bush up to 10 feet or more in height, which at the end of May or early in June produces lovely feathery white inflorescences. The flowers are fragrant, a close inspection revealing the fact that the fluffy or fringed character is due to the petals being very long (exceeding 1 inch) compared with the width. It is interesting to note that the only other species, *C. retusus*, is a native of China. There is thus but one representative of the genus *Chionanthus* in the Old World, and one in the New World. The Chinese Fringe Tree flowers at the same season as its American ally, but is readily distinguished from it, as the flowering panicles of *C. retusus* are borne on the ends of the present season's growths,

SOME GOOD AND USEFUL HARDY SHRUBS.

THE OSMANTHUSES.

SEVERAL useful evergreens are found in this genus of shrubs or small trees, which may be planted throughout the greater portion of the British Isles although one or two kinds are only suitable for the milder parts. The best-known species is *O. Aquifolium*, which is sometimes known as *O. Aquifolium ilicifolius*. This, the Holly-leaved Osmanthus, is a native of Japan, whence it was introduced nearly sixty years ago. It is known here as a bush 6 feet to 10 feet high, but travellers in Japan mention plants between 20 feet and 30 feet in height. Its most noticeable feature is its dark, Holly-like leaves, which average about two inches in length and are those of the Holly except that they are arranged in opposite pairs, while those of the Holly are alternate. They go further, however, in their Holly-like character than is noticeable at a casual glance, for as the bushes advance in height the upper leaves lose their spiny character and the margins become entire as in those of the Holly. It is also possible, as in the Holly, to perpetuate the spineless form by rooting cuttings from the upper part of a mature bush. Plants so raised may produce a branch or two with spiny leaves, but as a rule the spineless character is maintained. The form with spineless leaves has been given the varietal name of *myrtifolius*.

Added to its usefulness as an evergreen, *O. Aquifolium* is worth growing for the sake of its fragrant, white flowers, which appear in small clusters from the leaf-axils between early October and Christmas. Besides the one mentioned above, there are other varieties, such as *rotundifolius*, a low-growing, compact shrub with dark green, rounded leaves; *purpureus*, with leaves of a dark purplish hue; and *variegatus*, with silver variegated leaves. There is also a variety or two with golden variegation. Of all the varieties, *purpureus* is the most useful, and perhaps even a better shrub than the type. This species and its varieties are quite hardy.

Another fairly well-known plant in gardens is *O. Fortunei*, a very vigorous shrub with large, dark, rather dull green, oval leaves, sometimes 3 inches to 4 inches long and 2 inches to 3 inches wide. In the milder counties it sometimes exceeds 12 feet in height. The white, fragrant flowers are borne during October and November. It is said to be a hybrid between *O. Aquifolium* and a somewhat tender Chinese species, *O. fragrans*. Although hardier than the last named, it cannot be grown so far North as the other parent. *O. fragrans* is recognised by its broadly ovate or oval leaves with spiny margins, and by its large, white, fragrant flowers. Although it can be grown out of doors in Cornwall, it is too

tender for border culture in the neighbourhood of London.

Within recent years two new species have been received from Western China: *O. armatus*, seeds of which were sent by Mr. Wilson to Messrs. Veitch early in the present century; and *O. Delavayi*, which was introduced to this country by way of France. *O. armatus* is described as growing upwards of 12 feet high in its native country. The thick, oblong leaves are sometimes as much as 6 inches long and $1\frac{1}{2}$ inches wide, dark green and edged with spines. The fragrant, white flowers are borne in autumn. It is yet

the right stuff, which the old time-worn paving-stones characterise so well, they present a feature of antiqueness which, if in keeping with the surroundings, is pleasing in the highest degree. This is admirably borne out in Lady Clayton's beautiful riverside garden at Harleyford, Bucks, as may be seen by the illustration below.

It is another thing, of course—savouring of incongruity and of much bad taste—when the modern antique, the carefully broken Victorian pavement stone, that of finely ground granite and cement, is introduced and associated with

A PAVED GARDEN NEAR THE RIVERSIDE AT HARLEYFORD, BUCKS.

too early to say whether it will prove as hardy as *O. Aquifolium*. The other new species, *O. Delavayi*, is a very different plant. Found in Yunnan, it is said to attain a height of 6 feet in that country, although it grows slowly here. It is distinct from other kinds by having its fragrant, white flowers produced from the points of the branches, as well as from the axils, in spring.

PLANTS FOR PAVED WALKS.

THE paved walks of the garden are in large degree a modern innovation, copies or imitations, doubtless, of those which have done duty as such—whether for the sake of convenience or expediency it matters not—for a century or more in wayside cottage gardens in all parts of our delightful rural England. And, moreover, they supply a want and have come to stay. In the first place, properly conceived and executed in

buildings genuinely antique, or even decidedly modern. In such instances the practised eye of the true garden artist or landscape gardener will at once miss the time-worn, unequal corners of the older flags, just as the hand of the connoisseur of antique furniture will miss and decide by touch alone whether the example before him is genuinely antique or not. In both Time has played a part, robbed or divested each of their sharp, rigid edges, moulded and fashioned them as Nature does in her own sweet way to the hillsides by which we are surrounded. Hence to get hold of the right material at the start is an important matter, and, if not reasonably attainable, then I would say, forsake all idea of pavement stone and accept the flattish rock formations of Nature instead. These, if more rugged of surface, will at least be less formal generally, while the interstices their irregular outlines afford will prove the best of abiding-places for the plants we have in mind.

The walks themselves—the stones—are, however, of fundamental importance. These constitute the setting, and the setting should be worthy of the gems: hence the need of a rightful conception

of the whole, so that the one may be truly wedded to the other, as though part of Nature's own. I have seen it otherwise—detected again and again in these matters attempts to wed May to December, with, as usual, the most disastrous results. I have also seen instances, even where the stones have been of the right kind, of that species of overplanting—it has its parallel in the over-jewelled fingers of the newly rich—which so crowds every crack and cranny with vegetable life as to make these pathways impossible or impracticable. There is no need for either. The preservation of the pathway as such is essential. It should never be nullified by foot-high plants at flowering-time, nor by others whose roundly cushioned tufts render high stepping or picking one's way necessary. These, indeed, are some of the things to avoid, some of the things

the more intelligently planted of these flagged ways there is no need for either, and the pedestrian should be able to pursue his way without regard to where the next step should be placed. In a word, though the selection of good plants is not large, there is enough for the purpose, ample to keep the central tread or the great proportion of the path quite free of large-growing things. In certain instances the sides of the paths or steps, should such exist, might be ornamented by some of the plants I have tabooed, using them in moderation, without attempting the herb garden in terrace walk or pergola path. Aubrietias and Mossy Saxifrages and their like in growth are too large, and they show to better advantage elsewhere.

Seeds of such things as *Erinus* and the miniature-growing *Dianthi*, among others, might be sown, though usually little bits of plants so inserted

THE DIANTHUSES OR PINKS.

(Continued from page 353.)

D. plumarius.—The wild form of the garden Pink, *D. plumarius*, has rose flowers and is single. There are, as is well known, many double varieties which please the grower of border flowers. At present we may draw attention to a number of beautiful single varieties for the rockery, the wall, or the edging. A packet of seeds will give many varieties, ranging from white to crimson, and many with deep-coloured zones. Named single varieties, such as *Beauty*, *Dove*, *Duchess of Fife*, &c., are very fine. *Cyclops*, which comes wonderfully true from seeds, is very showy.

D. Seguieri.—One of the Pinks which is best for rather large rockwork. It grows from 12 inches to 18 inches high, with two to four flowers together on the stems. They are pink, with a purple centre. It looks well near the top of a wall or on high rockwork. Flowers from June to August.

D. squarrosus.—This has clear lilac flowers on stems about a foot high, and, though not one of the best, is an easy *Dianthus* to grow almost anywhere. It has fringed petals, and flowers from June onwards.

D. suavis.—One of the *Dianthuses* which attract everyone by their habit and fragrance is *D. suavis*. It makes a close mat of small, grass-like leaves, which hang prettily over the stones, and are covered in the summer with a multitude of little, fringed, white flowers. Easy to grow.

D. subacaulis.—I have not grown this plant, which seems a good doer on the rockery. It has rose flowers on 6-inch stems, and makes a spiny-looking tuft of narrow grassy leaves.

D. superbus.—Unfortunately, not very long-lived as a rule, but pleasing all by its fragrant, whitish rose, deeply fringed flowers. It should be raised often from seeds, as it usually dies after flowering. It will grow almost anywhere. The flowers appear from May to August.

D. tener.—One of the prettiest of the small alpine Pinks, which has very small, cheery-looking pink flowers on stems of a wiry nature, and from 3 inches to 4 inches in height. It is good for a dry, gritty rockery or the moraine.

D. zonatus.—This is an easy plant to grow on the rockery or moraine. It comes freely from seeds, and can also be raised from cuttings. It has grassy leaves and large flowers of blush or pink with a dark zone. It varies slightly in colour from seeds, but is very easily cultivated in a light soil, and prefers lime. Flowers in the summer.

A number of other good, easily grown Pinks are sometimes offered. These include *D. furcatus*, *D. hirtus*, *D. intermedius*, *D. noeanus*, *D. pallens*, *D. pinifolius*, *D. pungens*, *D. sicutus*, *D. Simsii*, *D. tenuifolius*, *D. Waldsteinii* and *D. Wimmeri*.

Dumfries.

S. ARNOTT.

(To be continued.)

THE WILD FORM OF THE GARDEN PINK (*DIANTHUS PLUMARIUS*).

which, if thoughtlessly indulged in, make these pleasing phases of a garden less a pleasure than they might have been.

In the wayside cottage garden the chief garniture of these flagged ways is not infrequently moss, lichen, or indigenous *Spergula* or similar thing, and their dwarfness should prove an invaluable object-lesson to the gardener. It is another thing altogether, far beyond the limits of good taste, or taste at all, when one is confronted by *Corydalis*, *Candytuft*, Mossy Saxifrages in high mounded cushions, Lemon Thyme, foot-high *Campanulas* and *Dianthuses*, Rock Roses and others, through whose maze of tufts much steering is necessary to avoid them. In one instance I remember a party of visitors avoided the path and took to the adjoining turf, to the discomfort and annoyance of the owner. As a fact, however, pedestrianism in the ordinary way was a discomfort—I had almost said impossible. In

as to thread their way among the cracks of the stones will be found the better method for planting. Tufts of plants should never be inserted whole. The object is to garnish the sides of the stones, not to obliterate the latter from view; hence the value of "little bits" along their margins. The following are some good plants, though there is no pretension to a complete list: *Sedum corsicum*, *S. brevifolium*, *S. Lydium*, *S. hispanicum glaucum*, *Erinus*, *Linaria pilosa*, *L. hepaticæfolia*, *Dianthus cæsius*, *D. arvernensis*, *Thymus Serpyllum coccineum*, *Paronychia serpyllifolia*, *P. Kapela* (both ideal carpeters), *Leptinella scariosa*, *Mentha Requierii* (a veritable and fragrant gem), *Arenaria balearica* (preferably where it could climb steps or side walls), *Campanula pulla*, *C. pusilla* in variety, *Draba aizoides* (seeds or plants), *Helxine Solierolii*, *Acæna microphylla*, and *Antennaria tomentosa*, which is highly ornamental used in conjunction with red sandstone.

E. H. JENKINS.

SOME EASILY GROWN TULIP SPECIES.

COLOURED PLATE 1498.

UNTIL Mr. W. R. Dykes, of Iris fame, has completed his Herculean task of growing all the so-called species of Tulips from seed, we cannot say for certain of any Tulip, except a very few, "this is a species." This is the present state of our knowledge. Before the Neo-tulips of Italy or Savoy can be considered as having specific rank, we have "a deal to learn."

In these notes I use the term "species" in the old-fashioned, loose way, which, as we have no other at present, we must perforce stick to. I am sorry to say that I have to write in rather a pessimistic vein about the grand species which have come to us within the last two or three decades from Turkestan, Bokhara, Persia and elsewhere. Great hopes were raised at Wisley when *fosteriana* (immense scarlet) first bloomed. I remember so well Mr. S. T. Wright telling me that he thought it would be a good doer, and that his half-dozen bulbs had formed offsets. He has not mentioned *T. fosteriana* lately. Put what construction you like upon this silence, I feel sure that there are few, if any, gardens where *T. fosteriana*, *T. Eichleri* and, I may almost add, *T. Greigii*, really flourish. They may be kept alive, but that is all. It has been suggested that they are by nature a short-lived race and perpetuate themselves always in their own homeland by seed. They are, however, so magnificent that I plead for them as luxuries, just to be indulged in when one is "flush." All have large flowers and are of a brilliant shade of crimson or scarlet. *T. mauriana*, the lovely bright red with a pure yellow base, from Savoy, thrives and increases, and is one of the most brilliant of all Tulips; but is it a true species? The Bokharian *præstans* is a bright vermilion, base and all, and has several flowers on a stem. It is the best doer of what I venture to call the true large red species type. I have seen it grow fairly when left for two

or three years in light soil, and with lifting it every year myself in my heavier land I am able to keep it. *Kaufmanniana* (the Water Lily Tulip), usually a pale primrose, although there are bright red and deep yellow forms, can usually be relied upon. It flowers in early spring and seems quite at home in our gardens, although it is not a very rapid increaser. The smaller Tulips, as a rule, behave better. *Clusiana* and *Batalinii* certainly do, and they may be established on a rockery where they will get a good resting-place in summer. *Chrysantha* I have not grown myself, but I am told it is not such a good doer as the others. *Dasystemon* is the most satisfactory of all. It is a very dwarf

grower, and generally has more than one flower upon a stem; good, strong bulbs ought to throw three or even four. The exterior of the blooms is a sort of green, while the interior is pure white with a large yellow base. *Clusiana*, or the Lady Tulip, is very pleasing; it has bright rosy red marks on its external petals and a claret-coloured base. *Batalinii* is a sort of first cousin to the brilliant *linifolia*. I am told they come from different valleys in Central Asia, and that various gradations in colour are to be found among them. Mr. E. A. Bowles has two or three very pretty varieties in the rockery at Myddelton House. I do not think they increase, but they come up

chrysantha, *persica* (small, dwarf deep yellow) and the Algerian *primulina* (yellowish white)—are *Didieri* (pointed, crimson), *Didieri alba* (pure white) and *Marjoletti* (pale yellow, with rose blotches at the base of the petals). These may all be usefully used in suitable positions in rockwork, and in light soil will probably take care of themselves. *T. Sprengeri* seems to stand in a class by itself. It is very late in flowering and of a bright scarlet colour. I find this goes on for some years without being much the worse, and as it is a valuable addition to the summer flora at a rather sparse time, it is one that should be tried. I recommend it for clumps in borders. It seeds freely; in fact, most of the species do. Seeds readily germinate, but the lengthy period of waiting is deterrent. However, like it is with Daffodils, once the first weary wait is over, if the sowing is annual, a regular succession of seedlings may be kept up.

JOSEPH JACOB.

[We are indebted to Messrs. Barr and Sons, King Street, Covent Garden, W.C., for the flowers of the interesting Tulip species from which our coloured plate has been prepared.—ED.]

DIANTHUS DUCHESS OF FIFE IN THE ROCK GARDEN.

yearly and do not die. *Chrysantha*, if I remember rightly, was shown last spring by Messrs. Barr and Sons. It is a pretty red and yellow, and is well worth a trial, although I cannot say much about it from personal experience. Sir J. D. Hooker, in his "Flora of British India," says the bulbs are eaten in Baluchistan. It takes one back to those first planted in Holland in 1571. The Dutch in those days thought they had got hold of something to eat, and the first Tulips were promptly planted in a kitchen garden.

Three lovely and dainty Tulips which might be added to the above—*clusiana*, *Batalinii*, *linifolia*,

In the meantime any amateur who can spare a small propagating-frame in his greenhouse would do well to strike a few of such Roses as he finds difficult to grow in the ordinary way.

The other fine climber I should like to direct attention to is *Souvenir de Mme. Joseph Metral*. For size of bloom it has no equal. The flowers are very double, of grand exhibition shape and of a lovely cherry red colour, shaded crimson and vermilion. The Rose may be grown as a free bush, but its flowers need support, as they are so heavy. It is fine on a south or west wall, and would also make an excellent standard.

DANECROFT.

SWEET PEA NOTES.

Summer Treatment and Exhibiting.—By the time these notes appear, the Sweet Pea enthusiast will be either rejoicing in a display of magnificent flowers and eagerly anticipating the near approaching floral contests, or he is miserably disappointed by dire failures. In this latter case, rarely does he assign the blame to the right cause. Seldom will a grower admit that his ignorance or careless neglect has been mainly the cause of his unlucky disaster. Yet in the few instances of partial or total failure I have met with this season, almost every one could be attributed to the fact that the grower (neglecting the warning so oft repeated in these columns) made the mistake of working and preparing his soil when in an unfit condition; consequently, the drought, succeeding the very wet weather of March, baked his soil into huge, solid lumps, in which it was impossible for the Sweet Peas to grow. On the other hand, in the majority of gardens the Sweet Peas are better than they were last year.

Increased Popularity is evidenced by the number of extra classes one finds devoted to

his Sweet Peas well into bloom by the latter week of June, and then maintaining a succession of flowers well into the autumn. To attain this, the plants must be kept in a growing state. No seed-pod must be allowed to form, and all malformed flowers should be rigidly cut off. Give a syringing frequently to prevent the hardening and drying of the haulm, and applications of liquid manures (a little and often) will ensure the plants growing well into the autumn. Nitrate of soda and sulphate of ammonia sprinkled upon the soil (about an ounce to the square yard) before watering will materially help to promote new growths after several pickings have been taken. I have by these means often picked fine blooms in October from plants that commenced flowering early in July.

Exhibiting.—I have often felt that it is one thing to have first quality Sweet Peas growing in the garden, but a totally different thing to so stage them at an exhibition that they win the merited award. What is the reason for this? In the first place, too many exhibitors make the fatal mistake of attempting too much. Often have I advised would-be exhibitors to content

digested. If compelled to use a weak blossom, do not conceal it. The judge is sure to "spot" it, and then follows a closer scrutiny. Unless the rules compel a fixed number, use fewer sprays rather than stage weak ones. Finally, look at the National Sweet Pea Society's Too-much-alike List and do not stage synonymous varieties; do not neglect to correctly label your exhibits, and be sure to read the schedule of the show and obey the rules.

S. M. CROW.

NEW ROSES AT THE "NATIONAL" SHOW.

THERE was nothing very startlingly new at the National Rose Society's show held on Tuesday of last week, and a report of which appears on another page. At the same time, there were a number of very good seedlings shown, and the following received awards from the judges.

Augustus Hartman.—A seedling Hybrid Tea of vigorous habit with stout, bushy stems. Said

Mrs. Bertram Walker.

Margaret Dickson Hamill.

Augustus Hartman.

THREE GOLD MEDAL ROSES.

Sweet Peas in the schedules of the summer shows. Also one could not help feeling a throb of pleasure as one stood on a railway terminus station in London a few days ago and saw the number of people either wearing a button-hole of Sweet Peas or carrying bunches of them. The National Sweet Pea Society has accomplished a grand work, and at its show on July 16 at Westminster will be seen all the choicest and newest Sweet Peas, and no lover of this flower should miss this opportunity of seeing them.

Summer Culture.—During dry weather continue to give a thorough soaking twice or thrice a week, alternating with a good hoeing. After several pickings have been made, the plants require a restorative and a stimulant; therefore give either liquid manure or any of the prepared foods as recommended in my previous notes. Also remember that a mulch of well-decayed manure or spent Hops adds extra nutrition and materially helps to prevent loss of moisture.

Extension of Flowering Period.—Every grower, except he be a seedsman, should aim at getting

themselves with a six class rather than put up a weak dozen. It is true this advice has frequently been coldly received, oftentimes rejected. Yet I am convinced that it is a mistake to try too large a class, or to show in too many classes. Secondly, many exhibitors fail to recognise the superiority of a fresh Air quality three-flowered spray over a coarse, faded four. But such is a fact. Do not stage a weak four if you have an excellent three bloom spray. Again, it is essential that the exhibitor who means to have the premier award stages only those varieties that will successfully withstand the vitiating atmosphere of the show tent, and this knowledge can only be obtained by experiment, noting the behaviour of each variety (1) during transit, (2) in water, (3) in a hot, humid or dry atmosphere, and (4) in a draught. Of course, this entails a fair amount of labour and trouble, but it means all the difference between an honour or a blank; therefore know your Sweet Peas. Other points were fully dealt with in last week's issue (page 351) by Mr. Thomas Stevenson, whose advice should be carefully considered and

to be perpetual flowering and good for exhibition or bedding. The blooms are large, deep and slightly conical in the centre, the individual petals being very large. The colour is rich glowing vermilion scarlet, reminding us in this respect of George C. Waud. The fragrance, though not powerful, is very pleasing. Shown by Messrs. B. R. Cant and Sons, Colchester. Gold medal.

Margaret Dickson Hamill.—A seedling Hybrid Tea, good for exhibition or bedding. The plant as shown has a very branching habit and spiny stems, but the blooms are not too erect. They are of good size and substance, fairly full and slightly conical. Colour, yellow, flushed with apricot. Not very fragrant, though slightly Tea-scented. Shown by Messrs. Alex. Dickson and Sons, Hawlmark, Newtownards. Gold medal.

Clytemnestra.—A seedling Hybrid Tea suitable for garden purposes and said to be perpetual flowering. A cluster Rose, the blooms being produced in large trusses. The open flowers are of ragged shape and of blush white, flushed

AN EFFECTIVE VIEW IN A READER'S GARDEN.

apricot colour. Shown by the Rev. J. H. Pemberton, Havering-atte-Bower. Gold medal.

Majestic.—A seedling Hybrid Tea of vigorous, upright habit with stout, spiny stems. The flowers are large, deep, of good substance, slightly conical in shape, and very sweet scented. The colour is glowing soft vermillion pink. Shown by Messrs. William Paul and Son, Limited, Waltham Cross, Herts. Gold medal.

Mrs. Bertram Walker.—A seedling Hybrid Tea of erect branching habit, and said to be perpetual flowering. The flowers are borne on stout, erect stems, and are of medium size, have plenty of depth and substance, and are of rather conical habit. The colour is a glowing cerise pink. Shown by Hugh Dickson, Limited. Gold medal.

Mrs. Maud Dawson.—A large Hybrid Tea seedling of branching, dwarf habit and evidently free flowering. Said to be good for bedding or exhibition; certainly it will be excellent for the latter purpose. The blooms are very full and conical, and leave nothing to be desired in shape. Colour, deep bright crimson. Very fragrant. Shown by Messrs. Alex. Dickson and Sons, Hawlmark, Newtownards. Silver-gilt medal.

Dorothy Varden.—A hybrid rugosa, making a large shrub or bush 4 feet to 5 feet high and said to be perpetual flowering. The blooms are freely produced, semi-double and slightly fragrant. The half-open flowers are glowing apricot salmon pink, changing to a much paler shade as they age. Shown by Messrs. George Paul and Sons, Cheshunt. Certificate of merit.

Mrs. Arthur Bide.—A seedling Hybrid Tea, the result of a cross between Mrs. T. W. Massey and Souv. de Catherine Guillot. Habit vigorous and branching, and said to be perpetual flowering. Might be aptly described as a double Irish Elegance. Only slightly fragrant. Shown by Messrs. A. Bide and Sons, Limited. Certificate of merit.

WATER AND ROCK- WORK IN A SMALL GARDEN.

THE small pond shown in the illustration is a very effective feature in a little villa garden of the usual rectangular type.

On three sides it is surrounded by rockwork facing south-west. At the very top a Clematis (*Viticella*) is planted and trained over trellis-work. It has to be vigorously cut back below, or it would soon smother the whole rockery. At its foot is a small Gorse bush, which flowers intermittently, as it does on our commons. "When the Gorse is out of bloom, kissing's out of season." A little lower there are, to right and left, patches of purple Aubrietia, and, contrasting well with its fine glaucous "grass," a tuft of Pinks. Among and between these are Daffodils; the flowers were just over and cut when the photograph was taken, but the long leaves show plainly. There is a big patch of *Iberis sempervirens* (perennial Candytuft) in full bloom in the middle of the picture, and just above, and to the left, a strong clump of the wild yellow Iris of our English

brooks. It is in flower in June, and the seed-vessels are very decorative later on, though, if left, they scatter much seed, and a careful removal of seedlings is necessary. To the right, above the Iris, is the old familiar double white Arabis, tumbling down that side of the rockery like a sheet of snow. I cut it well back after flowering, as it is a great invader. At the right edge the leaves of a pale blue (Kelway) Larkspur can be seen.

The water is just below the large Iris group; but an Iris with very narrow leaves and veined purple flowers in June, planted at the near edge, hides much of it. Some plants of *Leucojum vernum* are in flower a little to the right of the Iris, and then the dark red, early growths of a very fine *Astilbe rivularis*, a sort of giant and hardy *Spiraea*, fill up the space to the edge. They grow 2 feet or 3 feet high, are very much divided and graceful, and the flower rises to 5 feet—a great toss of creamy inflorescence in summer. In front, to the right, is a clump of self-sown *Solidago* (Golden Rod) that will grow too tall and must be eliminated, and it joins on to a large piece of Cone-flower (*Rudbeckia*), which flowers in autumn. It is also too tall when fully grown, and should have a place elsewhere, as it hides the water. Then, very much mixed up together, but all thriving on the steep slope, are Wallflowers, spring Forget-me-nots (removed when out of bloom), *Sedum rupestre*, London Pride and a white-flowered Carnation. The *Sedum* (rosy purple) flowers from September right on till November. A tiny, low-growing *Campanula* (*pumila alba*) lies like moss on the ground to the extreme left. Hardly visible, there is also a great deal of *Myosotis palustris*, the summer-flowering Forget-me-not, which begins to bloom in June, and has large, handsome flowers.

The Water Lily, shown in the other illustration of the surface of the pond only, is *Nymphaea Helvola rosea*. The leaves are coppery and quite small, but the flowers are a good size and have deep rose centres and yellow stamens. It flowers well, but would not do so if the surrounding plants overshadowed it, and that is one reason why only low-growing plants should be to the south of the pond side. The handsome leaves of a *Funkia*, growing under the *Astilbe*, are also visible in this picture, and the leaves of an ornamental striped grass. Between them and the Iris, the flat, disc-like leaves of Kingcups (*Caltha palustris*), may be noticed. There is a Water Plantain also in the pond, but it does not show, nor a piece of Buckbean I have lately introduced. M. W. S.

WATER LILY POOL IN A VILLA GARDEN.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Grapes which are quite ripe will require some protection from sun, in order to keep them in good condition for as long a time as possible. If ordinary garden nets are available, they will answer the purpose well, as besides shading the ripe Grapes they will be the means of preventing birds from entering the vineries and picking the berries. Ventilate freely, and only employ sufficient fire-heat to dispel moisture during damp weather.

Strawberry Plants for early forcing should be potted into 6-inch pots as soon as ready. Wash the pots and crocks before they are used, and make the soil firm without breaking the small ball of soil. Turfy loam, with a small quantity of decayed horse-manure, will suit them well. A sprinkling of bone-meal mixed with the soil will be an advantage. After potting, the plants should be placed in a shaded position and syringed twice daily while dry weather lasts.

The Flower Garden.

Pentstemons.—These plants are pushing up their flower-spikes, and should be encouraged by frequent applications of clear water at the roots. Keep the surface soil stirred with the Dutch hoe, and secure the flower-spikes to neat sticks before they are injured by rough wind.

Carnations.—Border Carnations will now require attention to tying up the flower-spikes. Keep the Dutch hoe at work among the plants, and if dry weather continues, give a good watering of clear, soft water. The layering of next season's plants should be accomplished as early as possible, in order to allow the young plants to become established in their flowering quarters before the season is too far advanced.

Sweet Peas.—These plants must receive a liberal supply of moisture at the roots during dry weather. Manure-water from the farmyard may be freely applied, but never of sufficient strength to injure the young roots. If decayed manure is available, a good mulching should be given previous to a soaking of clear, soft water. As the flowers die off, the seed-pods must be removed, in order to prolong the flowering period. Keep the stems close to the supports, so that the leading shoots may always grow in an upright direction. Weak soot-water is an excellent stimulant.

Spring-flowering Plants, such as Wallflowers, Myosotises, Polyanthuses and Violas, which have been raised from seed should now be ready for pricking off. This must be carefully performed, and the plants watered before they have time to flag. Frequent damping will be necessary until the plants become re-established.

The Rock Garden.

Watering.—Plants in exposed positions must receive careful attention to watering, which should be applied through a fine rose, so that the soil may not be washed from its position. Cut over all plants as they pass out of flower, and proceed with the propagation of young stock for spring planting.

Alpine Poppies.—These, *Papaver alpinum*, are now flowering freely, and present a very attractive appearance in the rock garden. They are easily raised from seed, which may be sown now to produce plants for flowering next season.

Auriculas.—Spring-sown seedlings should now be potted singly in small, clean pots and encouraged to grow freely. Care must be taken to protect the young plants from sun. Repotting of old stock should be carefully attended to, and the small offsets of choice varieties be placed under a hand-light, where they are almost certain to take root.

The Hardy Fruit Garden.

Young Fruit Trees which were planted in spring must be well supplied with moisture at the roots during dry weather, and, if not already done, a mulching of farmyard manure should be applied at once. Syringe the trees as often as circumstances will permit, either in the early morning or evening. Young trees planted against south or west walls must have daily attention in this matter, or they may suffer seriously and become permanently stunted.

Raspberries.—The crop is ripening fast, and should be secured as soon as ripe and per-

fectly dry for preserving. Fruits required for dessert should be carefully netted, and if protection from strong sun can be provided, so much the better. If the shoots have grown freely, they may be tied in such a way as to partly shade the fruits without making the covering too dense. When the crop has been gathered, all the old fruiting stems should be removed and the young shoots secured to wires or sticks. Four or five good strong shoots will be sufficient for each plant, as overcrowding must be avoided if good results are desired.

The Kitchen Garden.

Celery.—The principal plantation of Celery should now be finished, and if dry weather prevails, the plants must receive constant attention to watering. Earth up the early plants as soon as large enough, taking care to keep the hearts of the plants quite free from soil.

Leeks.—Plants intended for winter use must now be put in drills 18 inches apart and 12 inches between the plants in the row. Plants intended for large specimens should now be ready for earthing up. This must be done several times during the season. The Leek is a gross feeding plant, and will repay the cultivator for liberal treatment. Water freely with liquid manure. Soot-water is also a good stimulant for this crop.

Parsley for winter supplies ought to be sown as early in the month of August as possible. When the crop has grown a few inches high, the plants should be cut close to the ground, so that a quantity of sturdy leaves may be produced, as these will stand the winter better than long, spindly growth. If a cold pit is available, the seedlings may be thinned out and transplanted into the cold pit for use in rough wintry weather.

Endive.—The principal sowing should now be made and the plants thinned and transplanted. As soon as ready, some part of this plantation may be made where protection can be given during winter.

French Beans.—These should now be planted in cold pits for use during October. Plant in rows 2 feet apart, and keep the lights off until the approach of frost.

Globe Artichokes.—Give liberal waterings of liquid manure, and cut as soon as large enough, whether they are required for use or not.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Watering.—The heavy rains which fell in many parts of the country during the latter part of June were the means of saving many of the vegetable crops, which had been suffering severely. They will now be growing freely, and with many of the choicer vegetables, such as Peas, Celery and Cauliflower, occasional waterings with liquid manure will be very beneficial. If this cannot be secured, good results may be had from sulphate of ammonia at the rate of an ounce to the gallon of water, or, if used in a powdered state, an ounce to the square yard would be sufficient.

Late Peas.—The latest-sown Peas will require special attention just at present, as, if allowed to become dry, the crop is more than likely to end in failure. If manure can be had, it will be well to spread some on each side of the row, afterwards giving a plentiful supply of water, which will ward off attacks from mildew.

Small Salads.—Continue to make a small sowing of Radish once a fortnight, and for Mustard and Cress a sowing may be made once a week.

The Flower Garden.

Wallflowers.—The young seedlings should now be ready for pricking out, as, unless they were very thinly sown, the young plants soon become drawn and spindly. Prick out in soil of a free-rooting medium made moderately firm, about 3 inches apart and 9 inches between the rows; at least, a sufficient width to allow the hoe to ply between them. The aim should be to build up nice sturdy little plants that will withstand severe winter weather.

Roses.—The season so far has been favourable to Rose-growers, although some of the varieties have been more or less attacked by mildew,

which not only renders them unsightly, but has a very weakening effect on the plants. I find most of those affected have suffered from dryness at the roots. Now that many of the earlier blooms will be over, the faded flowers should be picked off and the shoots slightly shortened. They will be the better for liberal applications of liquid manure, or, failing that, some approved Rose manure. I have used fish manure with very good results.

Spring Bedding Plants.—A number of those sown last month should be almost ready for pricking off, and, as in the case of most plants that have to stand the winter, it is of the utmost importance to have them well rooted.

Codonopsis ovata.—This plant, with its strikingly beautiful blooms, will now be going out of flower, and the flower-stems should be shortened to induce it to break into growth again. Perhaps its proper position is in the wall garden or hanging over stones in the rockery, where the beauty of its flowers can be better seen. It is an old-fashioned plant, but one that is well worth a place in any collection.

Plants Under Glass.

Cyclamen.—The most forward of the old plants will be rooting freely, and will be greatly assisted with an occasional watering with soot-water, which I find not only strengthens the foliage, but also tends to keep the soil sweet. Admit air freely now, and on fine nights the lights may be drawn down, when the plants will derive much benefit from the evening dews. Seedlings from last August sowing should be ready for potting on into 6-inch pots. After potting, keep them close for a time, syringing twice daily.

Poinsettias.—By this time all the young plants should be rooted, and the most forward ready for potting on into 4-inch pots. As soon as they have taken to the new soil, expose them to sun and air, so as to encourage a sturdy growth.

Show Pelargoniums.—Those plants that have flowered and have been placed in frames or outside should now be sufficiently ripened so that they may be cut back and placed in frames till growth commences. After this they may be shaken out and repotted. Replace them in frames and water very carefully for a time; indeed, a syringing twice daily will keep them moist enough for a week or so.

The Hardy Fruit Garden.

Strawberries.—No time should be lost in securing runners for planting either in the autumn or the following spring. If suitable ground were available, they could be planted right away. Where, however, this is not possible, they may be run into nursery lines in a well-prepared border, and, should the weather be dry, they will require copious supplies of water from time to time.

Wall Trees.—The heavy rain experienced in many districts some weeks ago has had a very beneficial effect on all wall fruit trees. Not only has it cleansed the foliage of insect pests, but it has caused the fruit to swell nicely. Attention must be paid to stopping the shoots and laying in those required to furnish the walls. The regulation of shoots on Morello Cherries should be seen to at once, and protect the fruit with nets without delay.

Fruits Under Glass.

The Orchard-House.—Pot trees will require very careful attention now, particularly those approaching the ripening stage. In the case of the latter, artificial feeding should be discontinued, as well as the use of the syringe. Apples and Pears should have their fruits supported with raffia, and in the case of the former the pots should be plunged in ashes out of doors to finish the colouring of the fruits. A temporary erection should be put up, over which a net can be thrown to protect the fruits from birds.

Melons.—Young plants raised from seed, which in most cases will form the last batch should be planted out without delay. I find it useful to put a few plants in large pots and grow them in odd corners, and from these a serviceable supply of fruit can always be depended on. For this late batch the leading shoot should be stopped at about three feet, to induce the plants to throw out laterals more quickly.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

ANSWERS TO CORRESPONDENTS.

MISCELLANEOUS.

ROSES FOR TERRACE WALL (M. M. C.).—As you desire Roses to fall over the top of the 10-foot wall, you need varieties that have somewhat pliable growths. We think the following dozen would meet your requirements: Pale pink—Lady Godiva, Ethel, Grafen Ada Bredow and Débutante. Medium pink—Dorothy Perkins, Gerbe Rose, Coquina and Grafen Chotek. Deep rose—Minnehaha, Lady Gay, Climbing C. Testout and American Pillar.

PLANTS FAILING (Miss C.).—The Achillea appears to have been affected either by drought or fungus, which, we are unable to say, owing to the advanced stage of decay. The Inula is teeming with myriads of insect life, green fly particularly predominating and in sufficient numbers to undermine the constitution of any plant. Syringe the plants with a paraffin and soft soap emulsion, or, now that they have flowered, cut them down and burn the tops. The Violas may have been affected by drought, but we could not say without knowledge of the circumstances under which they have been grown.

NAMES OF PLANTS.—H. H. G.—The Clematis is a variety of *C. lanuginosa*.—*H. French*.—*Deutzia crenata* flore pleno; not an evergreen.—*McH. D.*—The Rose is Veilchenblau, known also as the Blue Rambler.—*Pinkieburn*.—Roses: 1, Souvenir de M. de Zayas; 2, Mme. Lambard; 3, Dean Hole; 4, Souvenir de W. Robinson; 5, Ulrich Brunner; 6, Mrs. S. Clark; 7, Mme. J. Grolez; 8, Admiral Dewey. As you sent no wood or foliage, it is impossible to say definitely what they are.—*Stoke*.—1, Alfred Colomb; 2, not identified; 3, Victor Hugo; 4, George C. Waud; 5, Mme. Ravary.—*J. H. W.*, *Manchester*.—*Hemerocallis fulva*.—*Bridport*.—*Sidalcea candida*.—*Avon*.—*Oxalis floribunda*; 1, *Philadelphus coronarius*; 2, Rose Gloire de Dijon.—*W. B.*—*Verbascum Chaixii*.—*Dandelion*.—1, *Campanula rapunculoides*; 2, *C. patula*; 3, *C. pusilla*; 4, *C. portenschlagiana* (quite hardy); 5, *Crepis rubra alba*; 6, *Calamintha Acanthos*.—*Mrs. F. F.*—1, *Sedum acre*; 2, *S. a. maweanum*; 3, *S. sexangulare*; 4, *S. asiaticum*.—*E. B.*—1, *Polygala vulgaris*; 2, *Alchemilla vulgaris*; 3, *Campanula rotundifolia*; 4, *Marchantia polymorpha*; 5, *Cystopteris fragilis*; 6, *Asplenium Ruta-muraria*.—*G. C.*—All three seedling forms of *Dianthus plumarius*.—*A. B. Bassett*.—1, *Juniperus virginiana aurea variegata*; 2, *Sequoia gigantea*; 3, *Juniperus chinensis* variety; 4, *Ailantus glandulosus* (Tree of Heaven); 5, *Populus marylandica*; 6, *Abelia rupestris*.—*J. H.*—1, *Kalmia latifolia*; 2, *Zenobia speciosa*; 3, *Rhododendron ferrugineum*; 4, *Kalmia angustifolia*; 5, *Leycesteria formosa*; 6, *Prunus Lauro-cerasus parvifolia*.

OBITUARY.

GEORGE CUTHBERT.

It is with deep regret that we record the death, on July 8, of Mr. George Cuthbert, head of the old-established firm of Messrs. R. and G. Cuthbert, The Nurseries, Southgate, Middlesex. Mr. G. Cuthbert was in his seventy-fifth year, and passed away after a short illness. He was well known in horticultural circles, and until recently was present at the fortnightly meetings of the Royal Horticultural Society. He was ever ready to assist the gardening charities, and his genial and generous nature endeared him to a wide circle of gardening friends. He was one of the oldest supporters of the Gardeners' Royal Benevolent Institution; indeed, the firm of which he was the head contributed to the funds of this admirable institution from its commencement. The interment took place at Christ Church, Southgate, on July 11.

Sutton Rose Society.—The thirty-third exhibition of this society was held at the Public Hall on Saturday, the 4th inst. The entries were not quite up to the numbers of former years, which is partly accounted for by Purley Show being held on the same day. It is a pity some arrangement cannot be made between secretaries to avoid this clashing of dates. The Sutton Challenge Cup, for forty-eight distinct varieties, was won by Messrs. F. Cant and Co., Messrs. D. Prior and Son being second and Messrs. Harkness and Co. third. In the open amateur classes, Dr. C. Lamplough again won the Vice-President's Cup, and Mr. J. Smart, jun., the Visitors' Challenge Cup. The local classes were well patronised.

SOCIETIES.

NATIONAL ROSE SOCIETY'S SHOW.

THIS society's thirty-eighth annual show of Roses was held in the Royal Botanic Gardens, Regent's Park, on July 7. From the exhibitor's point of view the show could hardly be described as a success, owing to the damage caused by the recent bad weather. In the amateurs' classes particularly, many of the blooms staged were unmistakably weather-beaten. The interest displayed in new Roses appears greater than ever, if we may judge by the long queues which besieged the seedling and new Rose tent throughout the afternoon. Descriptions and illustrations of some of the new Roses will be found on pages 368 and 369.

NURSERYMEN'S CLASSES.

There were six competitors in Class 1, for seventy-two blooms, distinct varieties. Messrs. B. R. Cant and Sons, Colchester, were the winners of the first prize, and hold for the year the Nurserymen's Champion Challenge Trophy and, consequently, become the champion Rose-growers among nurserymen for 1914. The blooms were on the small side, but perfectly fresh, glorious in colour, and even throughout. Second, Messrs. R. Harkness and Co., Hitchin; third, Messrs. Frank Cant and Co., Colchester; fourth, Messrs. D. Prior and Son, Colchester. Mr. John Pigg proved the winner of the first prize in Class 3, and in consequence holds the China Challenge Trophy for the year. The class is for forty-eight blooms, and among the pick of them were Mrs. Joseph H. Welch, George Dickson and Mme. Jules Gravereaux. Second, Messrs. G. and W. H. Burch, Peterborough; third, Mr. G. Prince, Longworth.

Messrs. B. R. Cant and Sons were again first for forty varieties, three blooms of each, their best trios being Ben Cant, Juliet, George Dickson, J. B. Clark and Edward Mawley; second, Messrs. D. Prior and Son, Colchester; third, Messrs. Frank Cant and Co.

A new class for twenty-four varieties, three blooms of each (Class 4), brought good competition. Messrs. G. and W. H. Burch were first, showing Elizabeth, Ulrich Brunner and Mrs. John Laing in capital form. Messrs. Burrell and Co., Cambridge, were a good second.

Another new class, for twelve varieties, three blooms of each, was won by Messrs. Chaplin Brothers, Limited, Joyning's Nursery, Waltham Cross. Caroline Testout and Florence Pemberton were well shown. Mr. C. Green, Hitchin, was second with a far inferior set of blooms.

The nurserymen's championship for Tea Roses (Class 7) and the D'ombain Cup were this year won by Mr. H. Drew of Longworth, Mr. George Prince being second, Messrs. D. Prior and Son third. Mr. Drew is to be congratulated on his success in this class, his best varieties being Mme. Jules Gravereaux, W. R. Smith, Maman Cochet, White Maman Cochet, Bridesmaid and Mrs. Myles Kennedy. Mr. Drew was also first in Class 9, for sixteen Tea Roses, three blooms of each.

For twelve Tea Roses, distinct, Mr. John Mattock had the best blooms. Molly Sharman Crawford, Mrs. Foley Hobbs and Mrs. Myles Kennedy were particularly well shown.

Messrs. W. Spooner and Sons were first in Class 18, for twelve varieties of summer-flowering decorative Roses (those which bloom only once in a year). *Rosa moschata alba* and *R. macrantha* were, perhaps, the pick of the twelve.

Mr. J. Mattock was first for twenty-four blooms, distinct varieties (Class 55), in very keen competition. Mr. C. Turner, Mr. C. Green, and Messrs. W. Crisp and Sons followed in the order named.

For twelve varieties, seven blooms of each, shown in vases, Messrs. D. Prior and Son were first. No other prizes were awarded in this class.

Mr. H. Drew was first in a similar class for nine Tea Roses, seven blooms of each, Messrs. D. Prior and Son being a good second.

The classes for perpetual-flowering decorative Roses were, speaking generally, very well contested, and these classes added in no small measure to the brilliance of this very large exhibition.

Roses shown in baskets were particularly effective, and the society does well to encourage, as far as possible, this effective mode of showing Roses.

For nine different varieties of Roses, shown in nine baskets, Messrs. Hugh Dickson, Limited, were first, thereby gaining the Kilbee Stuart Cup. Messrs. Chaplin Brothers, Limited, and Mr. W. Easlea were second and third respectively.

A similar class to the foregoing, only for five baskets, was won by Mr. H. Drew, followed by Mr. G. Prince and Messrs. S. Bide and Sons, Limited.

Another class in which eighteen varieties were shown in eighteen vases was won by Mr. C. Turner; while a similar class, only for nine varieties, was won by Mr. E. J. Hicks.

Messrs. Hobbies, Limited, were first for a magnificent group of Roses arranged on the floor of the tent. Messrs. William Paul and Son, Waltham Cross, were second, and Messrs. Paul and Son of Cheshunt were third. Weeping standard Roses of such varieties as *Hiawatha* and pillars of White Dorothy Perkins, together with good baskets of cut Roses, formed the leading features of these groups. The first prize group, it should be added, was one of the largest and most important exhibits in the show.

The Royal Botanic Society's Cup, for a group of cut Roses arranged on the staging, was won by Mr. F. M. Bradley of Peterborough. His blooms of *Maréchal Niel*, *G. C. Waud* and *Avoca* added considerably to the brilliance of his exhibit.

Messrs. G. Jackman and Son of Woking were first in a similar class. Among the varieties which adorned their stand were Mrs. Alfred Tate, Lady Pirrie and Countess of Gosford.

Messrs. Frank Cant and Co. were very successful with decorative Roses, gaining the A. G. Turner Cup and premier awards in three of the leading nurserymen's classes.

OPEN CLASSES.

The following classes were open to both nurserymen and amateurs: Twenty-four blooms, twelve blooms of a white and twelve of a crimson Rose. First, Messrs. W. and J. Brown, who staged capital blooms of Mrs. Carnegie and George Dickson. Messrs. B. R. Cant and Sons were second, and Messrs. Frank Cant and Co. third, the former showing Bessie Brown and Gloire de Chedane Guinoisseau, and the latter Frau Karl Druschki and George Dickson.

Eighteen Hybrid Perpetuals shown in a basket: This class brought to light one of the finest features of the exhibition, namely, a basket of eighteen Frau Karl Druschki, staged by Messrs. Prior. Messrs. Stuart Low and Co. were second for a very beautiful variety named Mrs. Charles Russell. No doubt we shall hear more of this variety as it becomes better known. Third, Messrs. Frank Cant and Co. for Ulrich Brunner.

For eighteen blooms of any Rose other than Hybrid Perpetual or Tea, Messrs. J. Cocker and Sons were first for Mrs. Andrew Carnegie, a variety that aroused great enthusiasm from all who saw it. Mr. W. R. Hammond, Burgess Hill, was second with Dean Hole. The class for eighteen Tea Roses shown in a basket was won by Mr. J. Mattock with Mme. Jules Gravereaux.

In a class for Rayon d'Or, shown in a basket, Mr. George Prince was a good first. Messrs. H. Dickson, Limited, were second and Messrs. S. Bide and Sons third. Messrs. J. Cocker and Sons were first for nine blooms of any new Rose, again showing Mrs. Andrew Carnegie in capital form.

Messrs. A. Dickson and Sons, Limited, were first for twelve new Roses; their varieties included H. V. Machin, Mabel Drew, Mrs. Cornwallis West and Duchess of Sutherland.

The dinner-table decoration, in which any member of the society could compete, was won by Mrs. A. R. Bide, who staged a particularly attractive table with the variety Mme. Herriot. Mr. E. J. Hicks was first for a bowl of Roses with his new variety Princess Mary. Mrs. A. R. Bide was second with the beautiful single variety Charles Ingram.

PREMIER BLOOMS.

Nurserymen.—Best Hybrid Tea, British Queen, from Mr. George Prince of Longworth; best Hybrid Perpetual, Horace Vernet, Messrs. B. R. Cant and Co. of Colchester; and best Tea, Mrs. Foley Hobbs, Mr. J. Mattock of Oxford.

Amateurs.—Best Hybrid Tea, Yvonne Vacherot, from Mr. R. de V. Pryor of Hitchin; best Hybrid Perpetual, Gloire de Chedane Guinoisseau, Mr. E. B. Lehmann of Crawley; and best Tea, Mrs. Foley Hobbs, Mr. C. Lamplough of Alverstoke.

AMATEURS' CLASSES.

The amateur champion class, for thirty-six blooms, distinct varieties, was represented by only three exhibits, the coveted distinction falling to the lot of Mr. T. E. Pallett, Earl's Colne, Essex. There were some very beautiful flowers, notably White Maman Cochet, Mrs. A. E. Coxhead, Mrs. Cornwallis West, Mildred Grant, Gloire de Chedane Guinoisseau, Princesse Marie Mertchersky, Frau Karl Druschki, Avoca, Hugh Dickson, Elizabeth, Maman Cochet, Dr. O'Donel Browne, George Dickson (grand), Florence Pemberton, Mrs. Stewart Clark, Mme. P. Euler, J. B. Clark (grand) and Mrs. Joseph H. Welch. A poor second was found in Mr. Conway Jones, Hucclecote, Gloucester. A less attractive series won third prize for Mr. W. Boyes, Middleton-on-the-Wolds, Yorkshire.

Class 38, for twenty-four blooms, distinct, was represented by only one exhibit, this being awarded first prize, and was shown by Mr. Conway Jones. The blooms were bright and attractive, though distinctly small. Ulster, Duchess of Bedford and Star of Waltham were the best blooms.

There were no entries in Class 39, for twelve blooms, distinct varieties, and only one exhibit in the class for twelve blooms of any Rose except Tea or Noisette. The prize in this class was offered by Messrs. Thomas Rivers and Son, The Nurseries, Sawbridgeworth, Herts. The variety shown was Mildred Grant, and the flowers were beautifully even and of good form and colour. The prizewinner was Mr. T. E. Pallett, who well deserved the distinction.

Open to Growers of Fewer than 3,000 Plants.

Four entries were forthcoming in the class for twenty-four blooms, distinct, in competition for the Hobbies Cup. A bright, clean lot of blooms won first prize for Mr. W. O. Times, Bedford Road, Hitchin. Beautiful examples were Mrs. Stewart Clark, Horace Vernet (charming), Marquise de Ganay, Hugh Dickson, Mrs. Foley Hobbs, Ben Cant, A. K. Williams and Ulrich Brunner. A good second was found in Mr. C. C. Eversfield, Denne Park, Horsham, a beautiful example of Maman Cochet being noteworthy. Third prize was secured by Mr. H. R. Darlington, Park House, Potter's Bar, Herts, with several excellent blooms, notably George Dickson, Bessie Brown and Ards Rambler.

Four exhibits in the class for twelve blooms of any Rose except Tea or Noisette were staged in friendly rivalry. Dean Hole securing leading honours for Mr. W. Times. Two or three of the blooms were very handsome; the others looked as if they had been kept for a time. Less interesting blooms secured second prize for Mrs. Bevil Portescue, Dropmore, Maidenhead, Berks; and with the same variety Mr. C. C. Eversfield gained third prize.

Open to Growers of Fewer than 2,000 Plants.

There were but two entries in the class for twenty-four blooms, distinct varieties, the first prize being awarded to Mr. F. A. Govett, Holiday House, Sunningdale, Ascot, for a good exhibit, considering the season, Mme. Jules Gravereaux, Lyon, Ulrich Brunner, Avoca, White Maman Cochet, Mrs. Howard Clark, John Cuff, Earl of Warwick and Maman Cochet being his best examples. Second prize was awarded to Mr. Gulliver Speight, Market Harborough, for rather small, though bright, flowers of pleasing form.

There were three exhibits in Class 44, for eighteen blooms, distinct. An excellent exhibit from Mr. R. de V. Pryor, Preston, Hitchin, well deserved the first prize it gained. Splendid blooms of Gloire de Chedane Guinoisseau, Mrs. Theodore Roosevelt, Mrs. J. H. Welch, Bessie Brown, A. K. Williams, Mrs. Foley Hobbs, Mamie, Mme. Jules Gravereaux, Mrs. J. Laing, Florence Pemberton, W. R. Smith, Mildred Grant and a glorious bloom of George Dickson were shown. Second honours were secured by Mr. J. Hart, Lochinver, Little Heath, Potter's Bar, with a neat and attractive exhibit. Gloire de Chedane Guinoisseau and Hugh Dickson were capital blooms. Mr. F. Slaughter, Steyning, was awarded third prize for a rather poor series.

Only three entries for nine blooms of any Rose except Tea or Noisette were forthcoming, a box of blooms of Frau Karl Druschki of even form winning first prize for Mr. J. Hart. Second prize was awarded to Mr. R. de V. Pryor for irregular blooms of Yvonne Vacherot; and with small blooms of Mildred Grant, Mr. Gulliver Speight was placed third.

In an extra class for Divisions E and F, for six distinct varieties, three blooms of each, there was only one exhibit. This came from Mr. J. Hart, and was awarded first prize. J. H. Welch, Florence Pemberton, Suzanne Marie Rodocanachi, Dr. O'Donel Browne, Frau Karl Druschki and Hugh Dickson were the varieties shown.

Open to Growers of Fewer than 1,000 Plants.

Six exhibits of twelve blooms, distinct, in the leading class of this division made quite a good show. Premier honours rested with Mr. Charles Lamplough, Kirkstall, Alverstone, who is always strong in this class. Superb examples of cultural skill were shown, and their names were Mrs. Foley Hobbs, Gloire de Chedane Guinoisseau, Frau Karl Druschki, Mrs. Welch, Avoca, Mme. Jules Gravereaux, J. B. Clark, Mildred Grant, William Shean, Bessie Brown, Lyon and A. K. Williams. Second prize was secured by Mrs. Henry Balfour, Langley Lodge, Headington, Oxford, with a very beautiful series, Florence Pemberton, Her Majesty, Charles Lefebvre and Rhea Reid being quite good. Third prize was won by Mr. Ernest G. Mocatta, Woburn Place, Addlestone, with a bright and attractive series of blooms of good form. This was a quite excellent stand.

Only one entry in Class 48 for nine blooms of any Rose except Tea or Noisette was forthcoming, Frau Karl Druschki, of medium size, winning first prize for Mr. Charles Lamplough.

Open to Growers of Fewer than 750 Plants.

The leading class for twelve blooms, distinct varieties, found no fewer than six competitors. Premier honours rested with Mr. F. H. Cook, Birch, Colchester, with a grand lot of blooms, not so well staged as usual. Notable examples were Mildred Grant, Frau Karl Druschki, Gloire de Chedane Guinoisseau, Juliet, Avoca, G. C. Waud, White Maman Cochet and Mrs. Coxhead. A capital box of blooms secured second prize for Mr. E. B. Lehmann, Ifield Lodge, Crawley, Sussex. Ulrich Brunner, Earl of Warwick, Bessie Brown and a superb example of Gloire de Chedane Guinoisseau were noteworthy. A dozen very neat and even, though rather small, blooms won third prize for Mr. Walter Stevens, Fair Oak, Radlett, Herts. The first prize in this class takes the Ben Cant Memorial Prize.

The seven entrants in the class for six blooms of any Rose except Tea or Noisette made a welcome show. First prize was awarded to fine examples of Dean Hole, which were shown by the Rev. F. R. Burnside, Great Stambury Rectory, Essex. Large, clean, chaste blooms of Frau Karl Druschki placed Mr. F. R. Biggleston, Jesmond, Puckle Lane, Canterbury, second; and with Mildred Grant, Mr. F. H. Cook was awarded third prize.

Extra Class for Divisions G and H.

The seven exhibits in this class made a very excellent display. Mr. Charles Lamplough was again to the fore, winning with good examples, the better blooms being Gloire de Chedane Guinoisseau, Mme. Jules Gravereaux and Mrs. Foley Hobbs. A good second was found in Mr. F. H. Cook, who had Mildred Grant in grand form. Third prize was secured by Mr. F. H. Fieldgate, The Cottage, Shrub End Road, Colchester, Avoca in his stand being very fine.

Open to Growers of Fewer than 500 Plants.

Only three entries in Class 52, for twelve blooms, distinct, were shown, Dr. W. P. Panckridge, Petersfield, Hants, being adjudged first with some really handsome blooms of high quality, Mrs. Theodore Roosevelt (superb), Mrs. Joseph Welch, Mrs. Stewart Clark, Mrs. A. E. Coxhead, Bessie Brown and Florence Pemberton all being noteworthy. Second prize was awarded to Mr. Stuart Hogg, Leaside, Hertingfordbury, with small, neat blooms; and third prize went to the Rev. F. G. A. Phillips, Taplow Rectory, Bucks, with a good series.

Class 53, for six blooms, distinct, was represented by seven entries. A grand lot of blooms won first prize for Mr. H. C. Baker, Bayfordbury, Hertford. Maman Cochet, White Maman Cochet, Dean Hole and G. C. Waud were grand. Mr. J. Smart, Sherwood, Stevenage, was a capital second, and the Rev. H. S. Arkwright, Breinton Vicarage, Hereford, was a pleasing third.

The class for six blooms of one variety had only three competitors. Dr. W. P. Panckridge was first with good examples of Dean Hole; Mrs. C. Giddins, Windmore Hall, South Mymms, Herts, was second with Mrs. Theodore Roosevelt, and with Avoca the Rev. F. G. A. Phillips was third.

Competition in the classes open to growers of fewer than 350 and 200 plants respectively was very keen, and the most praiseworthy interest was evinced in these classes by a very large number of visitors to the show. The flowers were good in most instances, reflecting great credit on the growers. Those who have never won a prize at an exhibition of the National Rose Society were also provided with classes, and these, as usual, were of considerable interest.

Metropolitan classes, too, for growers residing within eight miles of Charing Cross, brought out some very interesting competitions, showing how keen is the culture of Roses within the range of London smoke.

In Class 73, for six blooms of Lyon Rose and six blooms of Mme. Melanie Soupert, there was only one competitor, who had blooms of a somewhat mixed character. Mr. W. Boyes was awarded first prize, one good bloom of both varieties calling for notice.

Class 74, for the Hammond Prize for six blooms, new varieties, distinct, found five competitors. First prize was won by Mr. G. A. Hammond (the donor), Woodlands, Burgess Hill, Sussex, who showed six beautifully even examples of George Dickson, Mrs. Richard Draper, Mrs. Charles Hunter, Coronation, Frances C. Seton and St. Helena. Mrs. Bevil Fortescue was second, showing Mrs. Joseph Welch and Elizabeth in superb fashion. Third prize was awarded to Mr. H. L. Wettern, Waratah, Sanderstead, Croydon, George Dickson being his best bloom.

Exhibition Roses (Tea and Noisette).

For the Tea and Noisette Amateur Trophy, for eighteen blooms, distinct varieties, there were five entries, first prize being awarded to Mrs. Bevil Fortescue. The best blooms were White Maman Cochet, Mrs. Foley Hobbs, Mme. Constant Soupert, Medea, Mrs. Myles Kennedy, Maman Cochet, Nita Weldon, Molly Sharman Crawford, W. R. Smith, Auguste Comte, La Boule d'Or, Mme. Henri Berger, Mrs. Herbert Stevens, Comtesse de Nadaillac and Miss Alice de Rothschild. A good second was found in Mr. F. Slaughter, who had some noteworthy Roses in his stand—Maman Cochet, White Maman Cochet, W. R. Smith, Maréchal Niel, The Bride and Mrs. Myles Kennedy. Mr. C. C. Eversfield was placed third, and on his stand there were a few blooms of exceptional merit.

There was but one stand of blooms for Mrs. Alfred Tate's prize of a piece of plate, and this was somewhat poor. First prize was awarded, nevertheless.

Only one competitor again was found in the class for eight distinct varieties, three blooms of each. Mrs. Bevil Fortescue was again to the fore, winning first prize with a charming series. The better varieties were Maman Cochet, Mrs. Foley Hobbs, White Maman Cochet, Mrs. Hubert Taylor and Auguste Comte.

The two boxes of six blooms of one variety were very beautiful, and the blooms of White Maman Cochet which secured first prize for Mr. T. E. Pallett were a very beautiful lot indeed. They were even and of charming form. Mr. C. C. Eversfield was second with the same variety as the first prize winner, though less meritorious.

Open to Growers of Fewer than 500 Plants.

The class for twelve blooms, distinct, is always very interesting, the Rev. J. B. Shackle, Dropmore Vicarage, Maidenhead, leading the four competitors with a lovely series of blooms. The better varieties were Maman Cochet, Mrs. E. Mawley, White Maman Cochet, Mme. Jules Gravereaux and Mrs. Foley Hobbs. Mr. F. H. Cook was awarded second prize with an even series, in beautiful condition; third, Mrs. Henry Balfour with a pleasing exhibit.

Six exhibits in the class for six blooms of one variety were charmingly displayed. Leading honours fell to the Rev. F. R. Burnside with remarkably good blooms of White Maman Cochet. Second went to the Rev. J. B. Shackle for lovely blooms of Maman Cochet, and the third prize was awarded to Mr. F. H. Cook for grand examples of Auguste Comte.

Open to Growers of Fewer than 200 Plants.

The Prince Memorial Prize, for nine blooms, distinct varieties, found only one competitor in Mr. H. L. Wettern, who won the first prize with a beautiful series of well-grown blooms, White Maman Cochet, Mrs. Myles Kennedy, Mrs. H. Taylor and Mrs. Foley Hobbs being noteworthy.

Class 83, for six blooms, distinct, was represented by two entries only. Mr. R. de V. Pryor was awarded first prize with a well-finished lot of blooms, Mrs. Foley Hobbs, Mrs. Edward Mawley, Mme. Jules Gravereaux, Maman Cochet and White Maman Cochet being all that one could desire. A good second was found in Mr. Charles Lamplough, Mrs. Foley Hobbs, Mrs. Myles Kennedy and Mme. Jules Gravereaux being his best blooms.

Class 84, for six blooms of one variety only, was represented by six exhibits, a grand set of blooms of Mrs. Foley Hobbs gaining first prize for Mr. Charles Lamplough. Second prize was won by Mr. H. L. Wettern with Mme. Jules Gravereaux, and with six lovely White Maman Cohets Mr. H. C. Baker was placed third.

Open to Growers of Fewer than 100 Plants.

In Class 86, for six blooms in not fewer than four varieties, there were ten exhibitors. First prize was won by Mr. C. A. L. Brown, Hatfield Peveril, Essex, with six really capital blooms. Mr. J. Smart, jun., Sherwood, Stevenage, was second, and third prize was awarded to Mr. Arthur Merehouse, St George's Hill, Horley, Surrey.

The class for six blooms, distinct, found Mrs. Denman Murray, Horsenden, Ryde, Isle of Wight, leading the five competitors with quite good blooms. Mrs. F. Peters Wood, Broom Lodge, Weybridge, was second, and the Rev. F. G. A. Phillips was placed third.

Class 87, for four trebles, was an extra class for amateurs in Divisions III, IV, and V. A capital lot of blooms won first prize for Mr. F. H. Cook, who had Maman Cochet and White Maman Cochet in beautiful condition. The Rev. F. R. Burnside was placed second, showing superb blooms of the two varieties mentioned in the first prize series. A beautiful lot won third prize for Mr. F. Slaughter.

In Class 89, for a round basket of Tea or Noisette Roses, the first prize exhibit was very beautiful. Maman Cochet was splendidly represented in the first prize exhibit of Mr. F. H. Cook. A good second was seen in the blooms from Mrs. E. M. Wightman, Bengoe, Herts, who showed Maman Cochet.

Perpetual-flowering Decorative Roses.

Class 90, for three baskets of cut Roses, three distinct varieties, each variety in a separate basket, was represented by one exhibit only, Mrs. E. Wightman winning first prize with a charming trio. Ethel, Daphne and Mrs. W. Cutbush were the varieties shown.

There were five entries in the class for five stems each of five varieties. A beautiful set won first prize for the Rev. J. B. Shackle. Irish Elegance was well shown. These varieties, we were sorry to see, were not named. Second prize was won by Mr. J. Hart, who had Lady Ash-town, Pharisæer, Mrs. A. Tate, Mme. L. Pain and another. Third prize was secured by Mr. J. Walter Smith, Sparrows Herne Hill, Bushey Heath, Herts, for a really handsome series of blooms. Dorothy Page-Roberts, Lady Ashtown and Mme. Melanie Soupert were very fine.

Decorative Roses.

There were no competitors in the class for eighteen distinct varieties, not fewer than three nor more than twelve stems of each variety.

In the class for twelve bunches, however, the five exhibits made a grand display. Mr. H. L. Wettern well won the first prize with a grand lot of bunches, showing, among others, American Pillar, Crimson Rambler, Dorothy Perkins, Blush Rambler, Hiawatha, Dawn, Ethel, Auguste Comte, Mme. Abel Chatenay and General Macarthur. Second prize was won by Mr. Ernest G. Mocatta, who had grand bunches of Orleans Rose, Crimson Rambler, Dorothy Perkins, Blush Rambler and Irish Elegance. A charming series won third prize for Viscountess Enfield, Dancers' Hill, Barnet.

The eight entries in the class for six bunches, distinct, made a most glorious piece of colour. The winning series were those shown by the Rev. J. B. Shackle, and these, again, were unnamed, which is a distinctly unfortunate mistake. Mr. J. Walter Smith was placed second with a charming lot, Irish Glory being conspicuous. Lovely bunches won third prize for Mr. F. A. George, Red Hill, Worcester, who had Grüss an Teplitz and Mme. Alfred Carrière in good form.

Seven entries in Class 97, for six vases of wichuraiana Roses, were beautiful. Mr. H. L. Wettern again secured leading honours with popular varieties. Miss Beatrice H. Langton, Raymead, Hendon, N.W., was second with a freely flowered set, François Juranville being noteworthy. Third prize was awarded to Mrs. E. Wightman, who had Dorothy Perkins in beautiful form and colour.

Ladies' Artistic Classes.

For a basket of cut Roses, lightly arranged with any Rose foliage, there were seven competitors, first prize being awarded to Mrs. Colston Hales, Virginia Lodge, Warminster, for a distinctly artistic creation. A pink colour scheme won second prize for Mrs. A. E. Brown, Brookes Lodge, Reigate, and third prize went to Mrs. A. E. Clarke, The Hurst, Mottingham, Kent, for American Pillar, in glorious form and colour.

There were eight showing in the class for a vase of cut Roses, lightly arranged with any Rose foliage. First prize went deservedly to Mrs. Charles Williamson, Wilstead, Canterbury, for a wonderful vase of Gloire de Chedane Guinoisseau, in the pink of condition. Second prize was won by Mrs. J. Walter Smith with Irish Elegance, in lovely form, and third prize went to a warm colour scheme set up by Miss Jessie B. Langton, Raymead, Hendon, N.W. Dorothy Page-Roberts and Minnehaha were the varieties used.

There were seven bowls of Roses in Class 104. Gustave Regis, as shown by Miss Jessie B. Langton, and which won first prize, was lovely. A rather formal creation, using Irish Elegance and kindred coloured Roses, won second prize for Mrs. Colston Hales, and third prize was secured by Mrs. J. Walter Smith for a lovely bowl of Irish Elegance.

In other decorative classes for bowls, vases, baskets, button-holes, &c., the competition was very good, and some beautiful artistic creations were exhibited. The competition was very keen, and proves most conclusively how great a hold this aspect of the society's work has upon the ladies. Table decorations were numerous and very daintily arranged.

Class 101, for a table decoration of single Roses, was very popular, and found numerous entrants. Premier honours rested with Mrs. J. Walter Smith for a beautiful table of Rose Irish Elegance, in which lovely sprays of highly coloured blossoms were finely represented. Second prize was won by Mrs. Walter Morrison, who also used Irish Elegance, displayed in silver vases. In the third prize, won by Countess Olga Pontiatine, Glebovo, Egerton Road, Weybridge, Irish Elegance was again supreme, being lightly and deftly disposed.

THE GARDEN.

No. 2227.—VOL. LXXVIII.

JULY 25, 1914.

NOTES OF THE WEEK.

An Easily Grown Water Lily.—One of the most beautiful and, incidentally, one of the most easily grown of all Water Lilies is *Nymphæa Marliacea albida*. It will make luxuriant leaves and produce a succession of blooms if given about three feet of water. It is one of the freest to bloom, and may be safely recommended for the small garden if given all the sun possible and a pool of still water. It is well known that all Water Lilies prefer still water to a running stream. The flowers are very large, pure white, with light yellow stamens, and are fragrant.

Summer Treatment of Violets.—Plants which are intended to produce flowers throughout the winter should receive special attention for the remainder of the summer. Stop side shoots as they appear, in order to direct the energies of the plants to the formation of strong crowns, without which the results will not be satisfactory. Red spider, which is the most troublesome enemy to contend with, may be kept in check by frequent syringing and light dustings of soot; but no great quantity of soot should be applied at one time, or the tender foliage may suffer in consequence. Keep the soil stirred with a Dutch hoe, and if dry weather sets in, a good watering of clear soft water should be given.

The Nankeen Lily.—This beautiful Lily, *L. testaceum*, is totally distinct in colour, as the clear nankeen tint is not seen in any other. It is said to be of hybrid origin, and certainly in many points it resembles the supposed parents, the scarlet Turk's-cap Lily, *Lilium chalcedonicum*, and the Madonna Lily, *L. candidum*. In growth and size of flower it resembles the latter, while the flowers are prettily reflexed as in the former. Established plants under favourable conditions grow from 6 feet to 7 feet high, with horizontally poised heads of drooping flowers, which have bright red anthers. It is a plant that will grow in light, sandy loam better than many other Lilies, and, like the Madonna Lily, it should only be disturbed when absolutely necessary.

Interesting British Plants.—Among the more interesting British plants that have been sent to the Cambridge Botanic Garden in the past year are: *Gladiolus illyricus*, found in the New Forest and the Isle of Wight; *Lathyrus maritimus*,

the Sea Pea, a local species growing on pebbly seashores; *Erica Mackaii*, found in Galway and in Spain; *Nepeta Glechoma f. hirsuta*, a pallid micranthous form, found on the downs above Merrow in Surrey; *Viola riviniana f. luxurians*, Mr. Bickham's White Violet; *Salix Grahamii*, supposed to have been brought from Frouvyn in Sutherland by Professor Graham; *Saxifraga umbrosa*, from South Kerry; a Wallflower from Colchester and Guildford Castles (from these

18 inches to 2 feet high. The flowers vary from deep rich brown to bright yellow, many being beautifully spotted, and are borne in great profusion.

Rose Lady Alice Stanley.—This splendid Rose has done wonderfully well with us again this year, and we regard it as one of the best rose pink varieties for garden decoration. The blooms are fragrant, large, and held erect on stout stems, and the large, leathery leaves are seldom affected with mildew. This Rose ought to be in every garden.

The Mount Etna Broom (*Genista ætnensis*).—This is a most effective Broom during July and August, a season when flowering shrubs are not plentiful. Its graceful cord-like, arching, pendulous branches are almost hidden by the myriads of golden flowers. In common with the majority of the family, this Broom is happy upon rough, dry banks or in warm, light soils, which satisfy few things. As its name indicates, it comes from Mount Etna in Sicily, and appears to be perfectly hardy. It is readily raised from seeds, which are freely produced. This is the best means of increasing it, and as it is a fast grower, a good plant is soon obtained. It usually grows about ten feet high, but a fine specimen we saw the other day was almost twice that height and equally as far through, making a conspicuous feature against a background of large conifers.

Sweet Pea Week in London.—Sweet Pea enthusiasts had quite a busy time in London last week. The National Sweet Pea Society held its fourteenth annual show on Thursday, and followed it by a reception and dinner at the Hotel Windsor in the evening, when the innovation of a musical programme, generously provided by Messrs. James Carter and Co., was thoroughly enjoyed by a large gathering of members and friends. On Friday a number of members visited

A BEAUTIFUL WHITE WATER LILY: *NYMPHÆA MARLIACEA ALBIDA*.

and other castles always apparently the same form); *Verbascum* species, a critical form found in the grounds of Emmanuel College; and *Ulmus minor* (Miller), an interesting Elm recently found wild near Chatteris.

A Beautiful Strain of Hybrid Calceolarias.—One of the principal features in the conservatory at the Cambridge Botanic Garden is a display of hybrid Calceolarias, the result of crossing *C. The Bronze Age* with *C. Clibranii*. The plants are of a graceful branching habit, from

the society's trials at the Burbage Experimental Station, Burbage, Leicestershire, where Major Hurst very kindly met the visitors and later in the day explained some of the very interesting experiments that he is conducting on Mendelian lines with animals and plants. It is satisfactory to note that no fewer than 145 new members have joined the National Sweet Pea Society this year, and that twenty-two additional societies have become affiliated. A report of the London show will be found on another page.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Ostrowskia magnifica in Berkshire.—I enclose a photograph of a plant of *Ostrowskia magnifica* growing in the gardens here. As will be seen, the plant is growing at the foot of a wall which faces east, and the position appears to suit it well, the growth this year having reached the height of 6 feet. Last week, when at its best, it had fifteen fully expanded flowers open at one time, the largest being nearly eight inches in diameter.—E. W. DIE, *The Gardens, Bowden Green, Pangbourne, Berks.*

Cyclamen neapolitanum and its Seeds.—Surely there are few plants so tardy in maturing and ripening their seeds as is the above. Flowering as it does in August and September, it is usually the following June before we gather ripe pods from it, and there are many now (July 13) which have still to be gathered. When ripe, the seeds are at once sown in shallow boxes in a compost consisting largely of decayed leaf-mould and Cocoanut fibre, with an admixture and surfacing of fine loam. It is usually three years before the seedlings commence to flower.—F. HERBERT CHAPMAN.

Lilium giganteum in Scotland.—When visiting the gardens of Mr. T. Bennet Clark at Newmills, Balerno, Midlothian, on July 10, I noted, among a host of good things, two fine specimens of the above Lily in full flower. Both had flower-stems about six and a-half feet high; one bore eight flowers and the other eleven. Mr. Bennet Clark tells me that he frequently has this *Lilium* in flower. He raises his own stock from offsets, this being a saving of time as compared with seedlings (which some prefer), as they take about ten years to flower from the date of sowing.—CHARLES COMFORT.

New Rambling Roses.—In reply to your correspondent "E. M." on page 350, issue July 11, I must say I have not grown *Neige d'Avril*, but *Fräulein O. Hesse* I have had for some time, and consider it a lovely Rose, but not white. I do not call *Kaiserin Augusta Victoria* white. Since penning my first notes I have flowered *Sanders' White*, *Snowdrift* and *Mrs. M. H. Walsh*, all really grand whites. The first named is the snowiest white; but *Snowdrift* appeals to me more for its effectiveness. *Pemberton's White Rambler* will be valuable among the multiflora section, and a splendid companion to the old *Crimson Rambler*.—DANECROFT.

The Naming of Plants.—I undertook recently to name the flowers in a large garden in the North, but found that there were over twenty perennials I could not identify. Naturally, I hied to the nearest authorities, and, in order to ensure correctness, sent away duplicate sets of plants, one to the Botanic Gardens in the city close to us, and one to a large seed firm who had men specially "well up" in herbaceous plants. Now the results were astounding; in some five cases the actual genera were not the same, while over fifty per cent. of the others varied in the species. Without disparaging the excellent assistance given me in both cases, let me ask who is the authority? The garden in question is a very old one. On consulting my "Nicholson" I find room for doubt in the case of some names given, and even in that large work only a small number of species are noted. Again, suppose I have an unknown flower, how can I get it identified? Does the science of classification

remain in the hands of a few experts at Kew, and what authority is their knowledge based on? (The "Kew Index" probably, but how few libraries have it.) Wanting to get at the root of the matter, I have already made those enquiries, and have been answered; the gist of the answer being that I ought to study the "Floras" of various countries if I want to identify flowers myself! Here, again, are difficulties; must I keep all the "Floras" (our largest library in Scotland does not have them), and must I hunt through them all till I get my flower identified? Take the case of an ordinary gardener with an "unknown"; he has "Nicholson," which is worse than useless in this case; he studies catalogues of flowers and looks at pictures—also

A WELL-GROWN PLANT OF OSTROWSKIA
MAGNIFICA.

bad; he has not a classification table extensive enough to include all genera, even if he could work it; finally, he goes to "someone else" who knows better. Then we arrive at the original question—who is the authority, and does a full knowledge of classification rest in the hands of a chosen few? The question is opportune and interesting; but if the answer is as I suspect, surely we have need for some remedy!—H. H. A.

Bishop's Weed, Cow Parsley and the Roman Nettle.—Mr. Brotherston's humour seems to be of a very virulent kind. It is pleasing to know that the poor, neglected, ill-treated Bishop's Weed has at least one champion, and one who knows its virtues, though only supposed. But why resurrect King James? Certainly it is difficult to see the

point concerning Cow Parsley and its need for cultivation, unless it be to make botanising easier, though really much less interesting. One plant more should interest Mr. Brotherston; it is the Giant Roman Nettle (*Urtica pilulifera*). The writer remembers a fine patch of this plant growing in a garden in Kent. Every plant grew about six feet high, stout and strong in proportion, and truly a fitting monument to the ancient warriors who spread themselves over that fair county hundreds of years ago.—H. R., *Holland.*

Notes on Last Week's "Correspondence" Columns.—In your "Correspondence" columns last week I noted several most interesting topics on which I should like to comment, if you will allow me. The first concerned "The Most Fragrant Rose" (with a witty allusion to the Apostle and Prophet). I rejoice greatly to see the question of fragrance to the fore. It has been too long neglected. The next paragraph dealt with the appropriate naming of new plants, from "A. E. G.," a New Zealand writer, with whose opinions on the subject I strongly agree. I think especially the selection of personal names is objectionable, and oftentimes absurd. A friend recently desired to name a new Dahlia after me, an honour I hastened to decline; for, being no longer young or slim, I thought how terrible it would be to read remarks like the following in THE GARDEN: "Anne Amateur is of an old-fashioned type, now rarely seen, and, though of a fresh rosy tint, successfully enduring exposure to the strongest sunshine, and hardily resisting both storm and frost, is lacking in lightness and grace, and utterly superseded by more modern and attractive specimens." Then followed a most interesting note on "Lightness in Table Decorations," from H. A. Elliott. On this I venture these observations. To me Sweet Peas and Gypsophila long ago became wearisome. Though a good combination, it was a case of *toujours perdrix*, and made me feel like the London apprentices who in bygone days stipulated that they should not have salmon for dinner too often! For my part I think table decoration should vary in accord with the style of the dinner. With roast beef and plum pudding as principal items, bowls of Roses would go very well; while the flowers for a meal consisting chiefly of what our forefathers termed "kick-shaws" should be dainty in tint and light and airy in arrangement. I sometimes devise schemes for, and send flowers from my country garden to, a friend who (luckless woman!) has to give dinners in London in the season. One which met with great approval, on a broiling June evening, was as follows: In a large cut-glass centre bowl floated a few Water-Lily-like, small white single Pæonies, on leaves of the Winter Coltsfoot (*Tussilago fragrans*), real Water Lilies and leaves being then unobtainable. Some *Limnanthes* Douglasi counterfeited Water Crow's-foot. Round this little cool-looking Lily pond rose, in slender clear cut-glass vases, yellow Spanish Iris, with old-fashioned striped green and white Ribbon Grass and some wild Grasses. These stood on small glass plateaux placed on moss green plush. The guests voted the whole a great success. In conclusion, at the end of the "Correspondence" columns I came with surprise on my own name and an allusion to my village friend's recipe for White Rose ointment, with a request for a picture of the old ointment pipkin, which I will endeavour to send shortly. (Photographers are rather rare in the remote regions where I write.)—ANNE AMATEUR.

Rose Mme. Edouard Herriot.—I wonder how many amateurs have grown this Rose since it was sold by the nurserymen last autumn. No wonder such a great deal was written about it in the papers after it had received the Gold Cup. I have had four or five blooms off my plant. They are indeed a wonderful colour, and quite unique for a Rose. I can best describe the tints by likening them to that of the Sweet Peas Helen Lewis and Sterling Stent, which have been out at the same time as the Rose, and, putting them side by side, they have absolutely agreed with the Rose in colour. This is undoubtedly a great acquisition in the Rose world, and if lovers of Roses have not been fortunate enough to secure a plant this summer, they should lose no opportunity of securing one next November. I am so delighted with mine that I cannot help singing its praises for the benefit of others.—HONOR T. PITTS, *The Rectory, Loughborough.*

Rose American Pillar.—I can fully corroborate the remarks of your correspondent "H. G. B." on page 350, issue July 11, as to the merits of this beautiful climbing Rose. Like him, I purchased a plant from Messrs. Cannell and Sons when it was first introduced a few years ago, and since then it has been greatly admired by all. My only surprise is that even now so few are conscious of its merits. My own opinion is that in a few years' time, when more generally known, it will take premier position among rambling Roses. Many may be interested to know that it does equally well from cuttings planted in September in the open ground. In spite of the great merits of Blush Rambler and Dorothy Perkins, to my mind American Pillar surpasses them all. Good plants can be purchased at very moderate prices now, so there is no excuse for not possessing this charming Rose. While on the topic of Roses, I should be glad for information respecting another favourite of mine, Zephyrine Drouhin.—W. B. C., *Maidstone.* [Our correspondent does not indicate what sort of information he desires about Rose Zephyrine Drouhin. It is a great favourite with us on account of its wonderful fragrance, dainty carmine pink colour, and freedom of flowering. It is a Hybrid Bourbon, and does best grown as a large bush or pillar. Its stems are thornless.—ED.]

The Most Fragrant Rose.—It is to be hoped the judges for the Clay Challenge Cup will keep in mind beauty of form as well as fragrance when making their awards in the future. There was much diversity of opinion expressed at the Holland House Show regarding the decision of the judges, and many thought Mrs. George Norwood should have received the award. This Rose has a most perfect form and charming colour, and for fragrance is quite equal to the Rose that received the award, which from the illustration you gave on page 352 has no beauty of form to recommend it. The National Rose Society have very wisely recognised fragrance in their new rules for judging Roses for their gold medal, and no doubt raisers will give this matter due consideration; but I feel sure I shall have the majority of Rose-lovers with me when I claim for form that recognition it undoubtedly deserves. I was glad to find that the most beautifully formed novelty exhibited at the recent "National" Rose Show, namely, Mrs. Bertram Walker, possessed a delicious fragrance, and the judges were unanimous in awarding it a gold medal. I may say I do not like the term "scent" as applied to Roses and other flowers. The Crown Imperial has a scent

most obnoxious to one's sense of smell, and Mr. Sawyer in his excellent work, "Rhodologia," speaks of *Rosa platyacantha*, *R. Capucine* and *R. beggeriana* even developing an odour of bugs and coriander. He also asserts that cut Roses placed in a vase diffuse their fragrance more powerfully than when growing on the plant, so that, even for this, should not the award be withheld until the varieties are compared growing upon the plants?—DANECROFT.

The Horseshoe Fern.—I have seen the note by Mr. L. Stowe on this subject in the issue of April 11, and was surprised at his claim that the Fern is very rare and only known to grow in the vicinity of Mount Egmont. I quote from "Ferns of New Zealand," by H. C. Field, C.E., Member of the New Zealand Institute: "*Marattia fraxinea*. Para, Para Reka, or Para Tawhiti of the Maoris. Horseshoe Fern of the Europeans. This Fern is found in Guinea, Angola, Zambesi-land, Mascaren Islands, Natal, Cape Colony, the Neilgherries, Ceylon, Philippines, Malacca, Polynesia, Queensland, and Norfolk Island, besides New Zealand. It was formerly plentiful in the North Island (N.Z.), where its tuberous roots formed an important article of food, and caused the Maoris to assert they had a Potato before Cook visited the Colony. The wild pigs, however, have nearly exterminated it, so that it is only now found in a few localities, extending from the North Cape to a little south of Mount Egmont." Mr. Field also states it is the only plant of the genus *Marattia* in New Zealand, that it is only found in very wet, almost boggy, ground, and is easily cultivated in rich soil, kept well saturated with water, that cattle and horses both eat greedily of the fronds, which are said to grow as much as 14 feet high. I have specimens about five feet high which came from Waiuku, Buckland and Paparimu, bush districts all within forty-five miles of Auckland. I am told they are fairly plentiful on the Coromandel peninsula; and the district of Kaipara takes its name (Kai=food, and para=the edible Fern) from the prevalence of this plant in old times. A few years back I visited a fine group of Horseshoe Ferns (known here also as the King Fern) at Buckland, thirty-three miles south of Auckland, where the owner had reserved a clump of bush and fenced it to protect the Ferns from pigs and cattle, and I then saw specimens with fronds I could walk under. However, as Mr. Field says, they are fast disappearing wherever pigs and cattle range the bush, and it is only a matter of time when they will be very difficult to find growing in a state of Nature in New Zealand.—A. E. GRINDROD, *Woodside Road, Auckland, New Zealand.*

FORTHCOMING EVENTS.

July 28.—Royal Horticultural Society's Meeting and National Gladiolus Society's Combined Show at Vincent Square, Westminster.

July 29.—Flower Shows at Bishop's Stortford and Castleton.

July 30.—Midland Carnation Show at Edgbaston Botanic Gardens (two days). Royal Lancashire Agricultural Show at Liverpool (four days). Killarney Summer Show.

August 1.—Société Française de Horticulture de Londres Meeting. Dumbarton Sweet Pea Show.

August 3.—Flower Show at Carshalton.

August 4.—Flower Show at Abbey Park, Leicester (two days). Scottish Horticultural Association's Meeting.

THE SUMMER TREATMENT OF LAWNS.

I HAVE read with great interest your editorial note on mowing lawns without a grass-box, page 349, issue July 11. You draw attention to the great benefit derived by the lawn from the cut grass being left to decay, but you state as a drawback that the clippings would interfere with play if the lawn were used for tennis or croquet. It may therefore interest my fellow-readers of THE GARDEN if I describe a device by which it is possible to leave the clippings even on a putting green. While staying at North Berwick last month I walked over the links early one morning before breakfast. The men were working on the greens, and were carrying out an operation which from a distance greatly puzzled me. I walked up to them and found that they were sweeping the greens with long Bamboo poles. It appeared that the mowing had just been completed, and that the sweeping had the effect not only of spreading the clippings, but of rubbing them in and causing them to disappear. The Bamboos were about fifteen feet long. The butt was thick enough to be stiff for nearly eight feet, and this enabled the "waggly" end to be kept low and flat. Sweeping was done from side to side, and caused no fatigue. Playing over the greens later in the day, no one would have known but what every stray blade of grass had been studiously removed. The greens were as true as billiard tables.

If this is possible on a putting green, on which one plays with a light and easily deflected ball, no difficulty ought to occur in the case of games such as tennis, croquet or bowls. Moreover, the greater length to which grass is allowed to grow on tennis and croquet "greens" would make it all the easier to "rub in" the clippings. The whole secret lies in frequent mowing, so that the clippings are never long. Grass sufficient to form a crop of hay could obviously not be disposed of. But then mowing without a grass-box is so very much less laborious that frequent mowing may result in a saving of time and effort.

If you can spare the space, I should like to have an opportunity of stating my firm conviction that to leave on cut grass is the best of all possible means of manuring a lawn. All of us who are interested in farming know that land under grass slowly accumulates fertility. But if the land is heavily cropped, as happens to a lawn which is regularly mown with a grass-box from March to October, the exhausting process is more rapid than the accumulation of fertility. The finer grasses starve to death, and there remain only weeds, which can find a living practically anywhere. If, however, the grass is left on, nothing is taken out of the land, and it becomes richer and richer every year. This slow process of enrichment produces a totally different effect from the sudden application of powerful manure. I have applied the latter myself to lawns, and I have also watched the results in the gardens of friends. In every case the result has been eventual ruin. The explanation seems to be this: In a starved lawn the only vigorous subjects of the grass tribe are coarse things, such as the Poas and Yorkshire Fog. These alone are in sufficient health to benefit from stimulating food. (Do we not know Miss Jekyll's saying that to give manure to a sickly plant is like feeding a delicate child on beef steak and brandy?)

LANDOWNER

THE MORE DIFFICULT DIANTHUSES.

(Continued from page 366.)

ALTHOUGH a number of people have no difficulty with some of the Dianthus now mentioned, many cultivators find them more troublesome than the others, and I have, therefore, thought it desirable to write of them separately. They will generally thrive in a moraine, and can also be successfully treated in well-drained parts of the rock garden if surfaced

cause. *D. callizonus* is exquisite with its 2-inch or 3-inch stems bearing large flowers of brilliant pink, charmingly zoned and spotted at the base with a deeper hue. The bluish foliage sets off the beauty of the blooms. A few young plants, raised from cuttings or division, should always be kept. A cool, stony, peaty soil should be tried. It is a lime-hater. May and June.

D. Freynii.—There is a good deal of confusion existing respecting *D. Freynii*, *D. Lereschii* and *D. microlepis*. *D. Freynii*, however, is a most exquisite little plant, forming tufts of small green leaves rising but little above the soil. Above these are borne tiny flowers of rose or rose purple

D. neglectus.—I may be called in question for including this among the more difficult subjects. The true form has grassy leaves and, on short stems not more than 4 inches or 6 inches high, lovely flowers of bright carmine with the backs of a kind of nankeen colour. It is said to be unsuitable for the moraine, but this is not the case everywhere. I have grown it well on a flat part of the rockery, surfaced with fine gravel and grit, in peaty soil, and treated to good soakings of water in the summer months. Cuttings for the best forms, and seeds. May and June.

D. nitidus.—A dainty little plant, apparently a miniature form of *D. alpinus*, and calling for the same treatment. It therefore requires no further mention.

D. sylvestris.—Reputedly difficult, this Pink is not really so, but it may die off suddenly without any apparent reason. Belying its name of *sylvestris*, it is a lover of dry, open, stony places, and should be grown in the moraine or in dry soil with plenty of grit and surfaced with gravel or chips. It has small grassy leaves and red flowers on stems 9 inches high. May to July.

Dumfries.

S. ARNOTT.

DIANTHUS CALLIZONUS, A BEAUTIFUL DWARF PINK FOR THE ROCK GARDEN.

with an inch or 2 inches of large grit or small gravel or chips.

Dianthus alpinus.—This lovely species is quite easy with many growers, but others, through some obscure cause, find it difficult to cultivate. It has a preference for partial shade when on the rockery, but does not appear to be so particular on the moraine, in which it apparently delights. *D. alpinus* has large flowers of rose or pink, charmingly spotted with deeper colour at the base, and raised on stems 3 inches or 4 inches in length. The white variety, though pretty, is not so charming as the type. Under the name of *superbus* there is a large bright variety offered, as well as some so-called hybrids, which do not appear to be any improvement upon the lovely *D. alpinus*. It is easily raised from seeds or increased by division. May to July.

D. cal-alpinus.—Those who despair of cultivating *D. callizonus* may well attempt the exquisite *D. cal-alpinus*, the offspring of the marriage of *D. callizonus* and *D. alpinus*. It is a handsome plant with good rose flowers, effectively zoned with crimson. It does well on a sunny rockery or the moraine. It is raised from cuttings, and flowers in May and June.

D. callizonus.—Mr. Irving and the staff of Kew are to be envied the success with which they cultivate this lovely Dianthus there. It has a baffling habit of dying off without apparent

on short stems, the whole completing a picture which appeals to the alpinist. I have found that this will thrive on a level spot on the rockery if mulched with grit or fine gravel, and in a well-drained place, but watered during dry weather in late spring and summer. The moraine is the ideal place for it. It does not object to lime, but has no preference for it. June to August. *D. Lereschii* should have rose flowers, those of *D. microlepis* being white with lilac spots at the base.

D. glacialis.—The despair of many, the Glacier Pink is yet one of the flowers which are so exquisite that it well repays almost any amount of care. It is not, however, so very difficult in the ordinary sense of the term, except that it may die off even after we have indulged it by giving the prescribed treatment which has proved the best. This is a cool place, well drained but not too dry, but in a peaty soil, or one composed of loam, leaf-mould and sand with some grit in it. No lime should be given. It also requires plenty of water while growing. It has narrow leaves in tufts, and handsome pink flowers, rather smaller than those of *D. alpinus*. It is, in fact, not so desirable as the Alpine Pink. *D. gelidus* is generally considered a form of the Glacier Pink. It is smaller, and has pink flowers spotted with white at the throat. The same treatment suits it. April and May

THE FUTURE OF THE ANTIRRHINUM.

THAT the Antirrhinum is rapidly rising in popularity is now so apparent that it is unnecessary to labour the point; but one may feel sure of one's ground in asserting that very soon it will be the leading favourite with those who want a subject for either small beds or broad masses where a prolonged display of bright colours is desired.

Nurserymen and seedsmen have awakened to the possibilities of Antirrhinums, and a good many firms are devoting considerable attention to building up strains and sets of really good varieties. Before long, doubtless, growers will set themselves to the task of bringing out the best that is in the Antirrhinum by growing on single stems, pinching out all lateral growths—[We hope not,—ED.]—and by systematic feeding.

It is well that some thought shall at this stage be given to the future of the plant, for while it is in every way desirable that the work of selection and improvement shall be diligently pursued, it is devoutly to be hoped that no craving for sensationalism shall take hold of admirers of Antirrhinums, which would sooner or later prove baneful rather than beneficial. First, there is the possibility of the introduction of a host of named varieties. It seems to me it will be positively dangerous to the well-being of the Antirrhinum to tolerate the thrusting upon the market of a great many varieties under meaningless and useless names, simply because they are slightly different in colour from others. Antirrhinums may, of course, be propagated from cuttings with the greatest of ease; but if, in order to meet a short-lived demand for a novelty, resort is had to rapid multiplication by propagating under glass, it will not be long before the sturdy vigour and immunity from pests and diseases is destroyed. Let good strains suffice, and let us adhere as closely as possible to the rational method of raising from seed.

It may be all very well to grow a small number of plants on the single stem principle, to disbud,

and to feed judiciously in order to produce a few extra good spikes of flower; but do not let this fancy become a mania. Do not start an Antirrhinum society and offer challenge cups for spikes valued by the yard; but let the natural and beautiful bush-like habit, the free and continuous blooming propensities, and the sturdy constitution of the plant be jealously guarded and carefully preserved, and we shall be long able to enjoy one of the most serviceable and beautiful of plants, which, while worthy of gracing the most favoured of gardens, is accommodating enough to adorn the humblest and most unpretentious garden of the handicapped suburban amateur.

HEATHER BELL.

DISEASES OF THE TOMATO.

THE Tomato is a plant which has become popular only within the last few years, yet in a short space of time it has proved most susceptible to attacks of various fungi which are of the greatest virulence and

spread with astounding rapidity. Even more curious still, and unfortunate, too, is the fact that no cure, no reliable cure, can be found for any of them, and the only course open to the gardener is to ensure freedom for his plants by first-class culture coupled with extreme care at all times. Fresh turfy loam, or sterilised composts where extensive supplies of new material are not available, is the first great desideratum. Since the seeds carry spores of the diseases, clean seed or sterilised seed is almost essential, and when the plants are in active growth, health, vigour and sturdiness must be secured at all costs. A close, stagnant atmosphere in the greenhouse is most inimical to the health of the plants, and good feeding, but not "high" nitrogenous feeding, will be found to bring success. At the end of the summer, when the weather may chance to be close and "muggy," keep a little heat in the pipes to assist the air currents, to maintain a clear, buoyant atmosphere, and to banish that dank, stuffy, moist air that is the very harbinger of disease.

Black Spot.—This fungus (*Macrosporium Solani*) also attacks the Potato and causes the foliage of those plants to curl. In the Tomato the fruit is most commonly attacked, but a careful examination of the plants will probably show black or brown blotches on the stems and leaves. The disease generally begins as a pitted black spot near the eye or top of the fruit, and it spreads in rings, which are covered with a black velvet skin. Infection can only take place through a wound of the fruit; hence overfeeding leads to prevalence of the disease, since it induces cracks in the ripening Tomatoes. Avoid applying liquid fertilisers made from fresh manure, pull off fruits which show the fungus, and use them as soon as possible. Keep the place well aired

and fairly dry. Moist, stagnant atmosphere causes the spores to spread.

Black Stripe.—This is another very common disease difficult to get rid of once it finds a place inside the greenhouse. It appears at the lower parts of the plant first, but soon spreads upwards, first along the stem and then over the leaves. Do not scrape off the black streaks, for by this you are merely sowing the spores. Plants, especially when sprayed with fungicide, frequently recover, but never do well. The best plan is to dispose of any infested plant, to spray surrounding specimens with fungicide, and to dress the soil round about with quicklime.

Leaf Rust.—This disease is not so common as either of the above. It is characterised by yellow or light brown patches spreading over the leaves, which are really colonies of a fungus known as *Cladosporium fulvum*. This rust is fostered by bad ventilation and too much foliage on the plants. Defoliate a little more freely to allow free play of air among the plants, be sure to burn badly infested leaves, and, if the rust is again noticed, use a fungicide.

Sleepy Disease.—This disease—and a destructive and quick-acting one it is—makes its presence

soil should be dressed with quicklime and sterilised in the winter, or new compost replaced.

Bacteriosis.—This disease is held to be caused by a bacterium called *Bacillus solanacearum*, which also attacks the Potato. Tomato plants attacked by it begin to droop and die at the top. The disease gradually works its way down the plant, the leaves curl up and become marked with yellow spots. The fruits are attacked eventually, and soon the whole plant is useless. Burn all attacked plants, for there is no cure. The germs may be carried by insects from one plant to another, so use the liver of sulphur solution mentioned below immediately the presence of the bacillus is suspected. Bordeaux mixture, with half an ounce to an ounce of copper sulphate per gallon, is a good fungicide; but almost equally efficacious is liver of sulphur solution containing an ounce of that chemical and four ounces of soft soap in every two gallons. The Board of Agriculture recommends the admixture of an ounce of Paris Green with every ten gallons of Bordeaux mixture used in the case of bacteriosis.

A perusal of these brief notes shows the wisdom of careful work on scientific lines. Prevention must ever be the fetish of the Tomato-grower,

DIANTHUS NEGLECTUS, A SPECIES WITH LARGE BRIGHT CARMINE FLOWERS.

known by a sudden drooping of the foliage from no apparent cause, followed rapidly by the death of the plant. The stems near the soil appear covered with a dense white mould, turning brown in time. If the skin is removed from the stem, it is found to be black or brown underneath, and a section of the stem shows the internal tissues to be in a very unhealthy state. All suspected plants should be isolated immediately and burned if it turns out to be a case of sleepy disease. There is absolutely no cure, but the

for only in that way can he ever hope to secure the acme of success.

H. H. A.

AQUILEGIA STUARTII.

Of the many beautiful garden subjects which the Aquilegia family provides, few can compare in grace of form and delicacy of colouring with Stuart's Columbine. This dainty plant is said to be a hybrid between *A. glandulosa* and *A. Witmannii*, and was raised by Dr. Stuart. The

flowers have sepals of a clear full blue, while the petals forming the cup-like corolla are cream. The foliage is neat and dwarf, slender stalks holding aloft the delicately poised flowers, which are of very considerable size. This *Aquilegia* is said to come true from seed, but as I have not raised this form I cannot speak from experience. From the results I have had in raising other species of Columbine, however, I should consider this a remarkable feature in a family so prone to hybridise. My experience with the lovely *A. alpina* is that, if fortunate, one in a hundred seedlings *may* be something like the plant. The strongest plants usually follow sowing *in situ* and thinning out to prevent overcrowding, while a cool, deep, well-drained, gritty compost appears to be relished.

Other particularly attractive Columbines for some cool ledge in the rock garden are *A. cærulea*, a lovely blue, long-spurred species from the Rockies; *A. canadensis*, scarlet and gold, and its nana form; *A. chrysantha*, which sometimes attains a height of 3 feet 6 inches and is of a soft yellow and pink tone; and *A. pyrenaica*, a dainty Columbine resembling *A. alpina*, though paler in colour and rather dwarfer. The accompanying illustration indicates how attractive an irregular group of *A. Stuartii* may be when introduced in the neighbourhood of dwarf shrubs on some stony ledge in the alpine garden. R. A. MALBY.

SUMMER-FLOWERING MAGNOLIAS.

ALTHOUGH the summer-flowering Magnolias fail to produce the wonderful profusion of bloom which is such a characteristic feature of the earlier-flowering kinds, their blossoms are wonderfully beautiful, and in some instances they are borne over a period of several months. Unfortunately, the plants are, like their

AQUILEGIA STUARTII, A BEAUTIFUL HYBRID COLUMBINE WITH BLUE AND CREAM COLOURED FLOWERS.

earlier-flowering relatives, unsuitable for the colder parts of the country, and for that reason they are sometimes thought to be more tender than they really are, and are therefore excluded from gardens where they might reasonably be expected to thrive.

Sweet soil on the moist side and fairly free from lime suits them admirably, perhaps the most satisfactory rooting medium of all being formed by digging a little peat and leaf-mould into light loam.

Magnolia grandiflora is one of the most important summer-flowering species, for it is worth growing both on account of its fine flowers and hand-

some evergreen leaves. A native of the Southern United States, it is there known as the Bull Bay, and grows into a tree of timber size. Here it varies a good deal, according to the position it occupies. In the South and West Counties it is a familiar object as a large bush or small tree in the open ground, but in other places it is usually planted against high walls. In either position it is an eminently satisfactory plant, for its fragrant white flowers, which are often 9 inches or more across, are borne from early July until late September. The leaves on different plants vary in character. As a rule they are oblong in form and from 7 inches to 10 inches long, thick and leathery. Some, however, are covered by a dense, reddish brown pubescence on the under surface, while others are quite plain, intermediate kinds also being found. Several forms have been selected for varietal names. The best of all is *gloriosa*, a form with shapely leaves and large, handsome, cup-shaped blossoms, the petals of which are conspicuous by reason of their beautiful shape and the purity of their colour. *Angustifolia* and *lanceolata* are distinguished by their narrow leaves, *ferruginea* by the reddish under surface of its foliage, *undulata* by the undulating margins of its leaves, and *variegata* by its variegated leaves. The last named cannot be very highly recommended.

M. hypoleuca is a handsome deciduous tree from Japan. In that country it grows 70 feet or 80 feet high, but it has not attained half that height in this country up to the present, and good examples are rare. In leafage it most closely resembles the North American *M. tripetala*, the leaves being very large and handsome. The flowers are, however, more attractive than those of that species, for they are larger, more fragrant, and the petals of greater substance. The petals are alternately white and cream, and the stamens crimson. Expanded flowers are often 8 inches across. The bright red fruits are also of great decorative value.

M. Fraseri is one of the better-known kinds from the Southern United States, where it forms a tree quite 40 feet high. Here it often develops with a short trunk and large rounded head. Its

THE SWAMP BAY MAGNOLIA (*M. GLAUCA*).

handsome deciduous leaves are often over a foot long and 7 inches or 8 inches wide, while its creamy white or pale buff, fragrant flowers are from 6 inches to 8 inches in diameter. It may be considered as one of the hardier sorts.

M. glauca, sometimes called the Swamp Bay or Laurel Magnolia, may be either evergreen or deciduous, according to the locality from which the seeds were derived. It has a wide distribution in the United States, and plants from the more southerly limits are usually evergreen. Here it forms a bush 12 feet or 15 feet high, with oval leaves 3 inches to 5 inches long, the upper surface green and the under side glaucous. The white, cup-shaped flowers are between 2 inches and 3 inches across, and borne over a period of quite three months.

M. macrophylla is one of the aristocrats of the family, not only in flowers, but in foliage also. In its home in the Southern United States it grows into a large tree, but there are few really fine examples in this country, the best being in the garden of H.R.H. the Duchess of Albany at Claremont. The leaves of this species are sometimes 18 inches long and 8 inches or 9 inches across, bluish green above and silvery beneath. The fragrant flowers are pale yellow or deep cream in colour and 9 inches or more across. It is not very hardy in a young state, but after the first few years it appears to be better able to withstand cold.

M. tripetala, the Umbrella Tree or Elkwood of the United States, is also a decorative tree, for it has large leaves sometimes more than a foot long, and large white flowers, which are succeeded by showy red fruits. Between it and *M. glauca* a hybrid has been raised which is known under the name of *M. thompsoniana*. It is of rather loose habit and intermediate in character between the parents, perhaps more free flowering than either. The white blossoms are borne from June to August.

M. Delavayi is a new tree from Yunnan. In that country it grows upwards of forty feet high, but it is doubtful whether it will form a tree in this country except in the mildest localities, for it is not very hardy, even against a wall near London, the younger wood being liable to injury if a severe spell of frost is experienced. The

evergreen leaves are large and handsome, 7 inches to 12 inches long, 5 inches to 7 inches wide, and, on vigorous plants, of a bluish green colour. The creamy white flowers are 6 inches to 8 inches across, rather cup-shaped and fragrant.

M. acuminata, the Cucumber Tree of the United States, is perhaps the hardiest of all Magnolias, and at the same time the least ornamental. It grows into a tree 40 feet or 50 feet high in this country, with leaves 6 inches to 9 inches long and 3 inches to 5 inches wide, and

with small greenish flowers, which are succeeded by small Cucumber-like fruits; hence the common name. Closely allied to this is the smaller-growing *M. cordata*, also a native of the United States. Its yellowish flowers are more showy than those of the last named, but of no special merit. With the exception of *M. grandiflora*—the most important of them all by virtue of its beautiful flowers and handsome evergreen foliage—the summer-flowering Magnolias are not so well known as they should be.

ARCHES IN GARDENS.

WHEN suitably clothed with climbing plants, arches add considerably to the beauty of either flower garden or kitchen garden, always providing that they are suitably placed. It needs but a glance at the accompanying photograph, taken in Lady Clayton's garden at Harley-

ford, Bucks, to note how effectively an archway may be clothed even in a kitchen garden. In this instance the main walk in the kitchen garden is bordered with herbaceous flowers, and the effect is pleasing in the extreme. The wide arched openings in the walls, through which pleasant views are obtained, afford ample opportunity for the generous planting of suitable climbers. Clematis montana and various ornamental Vines, including Vitis purpurea and Ampelopsis hederacea, are used with delightful effect, mingled with Wistaria multijuga and W. sinensis. There is no lack of subjects suitable for planting in such situations, and in addition to those already mentioned the following are also to be recommended: Actinidia chinensis, one of the most beautiful of all hardy climbers in foliage, although the flowers are rarely seen; Aristolochia Sipho, or the Dutchman's Pipe, suitable for a warm aspect; Japanese and European Honeysuckles; Polygonum baldschuanicum, a beautiful climber from Bokhara, with a wealth of pink and white flowers, borne in June and again later in the summer; and Akebia lobata.

Roses are also well adapted for this purpose, and a suitable selection would include Alberic

Barbier, Rosa moschata alba, Rosa sinica Anemone (otherwise known as the Cherokee Rose) and Ards Rover. Such red-flowered varieties as American Pillar ought not to be grown against brick walls, for neither red nor pink flowers are seen to advantage in association with brickwork. With so wide a selection of climbing plants there is no reason why archways, with a little care in planting, should not be made both attractive and interesting at practically all seasons of the year.

ARCHWAY AND FLOWER BORDERS IN THE KITCHEN GARDEN AT HARLEYFORD.

ROSE-GROWING IN TOWN GARDENS.

THE removal of fading blooms, besides being necessary for the sake of tidiness, helps to conserve the energy of the plants, much of which is spent in the production of the flowers. In effecting this a certain amount of the growth is removed, so that a sort of secondary pruning takes place at this time of the year. It is sometimes a matter of difficulty for a gardener to know exactly how far the growths may be cut back. Those who like to gather their blooms naturally wish to have them with long stems, while others who prefer to see them in the garden are often loath to remove a fraction more of the wood than is necessary. There is no doubt that a wholesale stripping of the tree causes a loss of vitality, not only on account of the wasted sap,

thing in the nature of severe cutting is likely to lessen rather than increase the chances of good blooms in the succeeding crop.

A full-blown Rose is the favourite resort of earwigs, and these should always be looked for and destroyed as the flowers are gathered. One needs to examine the flowers night and morning for traces of these pests where they are numerous, for the damage they do is frequently very apparent if they are left undisturbed for a day. A good method of trapping these insects is to place a number of short lengths of hollow Bamboo cane upon the ground around the plants, and examine these each morning; but Rose petals are undoubtedly the finest form of "bait" for them, so one should make certain that none escapes when these are gathered. A particularly difficult pest is the earwig, and man seems to be almost the only destroying agency in our town gardens, for very few birds will eat them. Nature has a way of adjusting things, however, and, fortunately,

Cultivators should closely examine their plants. If they find the wood—stems—very hard now and the leaves small and tough, they should syringe the foliage heavily on every suitable day; if they find the stems soft and long-jointed, with very large, brittle leaves, then syringe much less frequently, as the proper maturing of the wood would be delayed too much. The object of the cultivator this month must be to promote a sound, healthy growth of plant, so that when the buds appear in August they will quickly develop, and also the surrounding shoots, to a stage when "taking" of buds will be work quickly carried out. Buds and shoots that are slow in developing to the stage when "taking" should be done usually mean short flower-stems, and short petals that are too narrow and too numerous when the blooms are fully out; but very frequently such buds never develop fully in the centre.

Early Feeding.—Very weak doses of clear soot-water and manure-water may be given as the roots fill the pots; but soot-water made from fresh soot and given very strong does much harm—it burns the tender roots. Clear liquid made from soot that has been stored in a shed for several months is the only kind fit to use. Dirty soot-water does harm, as the sediment blocks the pores of the soil.

Early Top-dressing.—This is very beneficial if done in the right way. Some very good loam must be passed through a half-inch-mesh sieve; treat half-rotted leaf-soil in a similar way; use two parts loam and one part leaf-soil. To a bushel of the combined parts add a peck of rotted manure, also sifted, a 6-inch potful of bone-meal, and a concentrated manure according to the instructions given with it. Now, instead of putting on the mixture in one thick layer, sprinkle on a little only—just enough to cover the surface soil in the pots, and then water through a rosed watering-can. In a few days' time, directly the young roots show through, put on another thin layer of the prepared compost. The cultivator can ascertain the true state of the soil below, as to whether it is dry or moist, by tapping the pots.

Side Shoots.—All side shoots must be pinched out while quite small, so as to concentrate the full strength of the plants in the main stems and leaves.

Premature Bud Formation.—Some varieties bear buds prematurely much more frequently than others. Any buds forming before July 25 must be removed at once, unless they are borne on very late-flowering varieties, such as the Hon. Mrs. Lopes; then, gradually "take" the buds, as later-formed ones would be useless if these are removed. On earlier varieties July buds must be removed, as those appearing at the end of August will be of better quality. AVON.

MILTONIA VEXILLARIA REV. W. WILKS

but because of the check which it gives to the roots. On the other hand, if only the stem of the flower is removed, the result is a superfluous number of weak, crowded shoots, which it is desirable to avoid. One may usually cut away about half the growth with safety, of course using discretion in doing so. There may, for example, be other buds which it is desired to see flower, in which case one would naturally sever the shoot at a point which would allow of this. It is also essential to bear in mind the future shape of each tree, and one should therefore cut to an outward eye.

Now that the first crop of bloom is past, it is a good plan to go over the trees carefully and slightly trim those that require it. Weak shoots which have come blind should have been removed in their earlier stages, but some are apt to get overlooked, and these ought to be cut out. The aim should be always to keep the centre of each plant open, and the timely removal of a few thin and useless branches will often help in doing so. But there should be no "hacking" of the plants, for any-

the winter proves fatal to most of them, or we should be overwhelmed. P. L. GODDARD.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

IN July, especially towards the end of the month, the plants grow freely if the roots are in a suitable medium. It is a fact that Chrysanthemums make very strong growth towards the end of the summer; more, it seems, in comparison, than in their early stages. The plants thrive best in a cool temperature; although they make rapid growth in spring if subjected to much heat, the quality of the shoots is very poor. As the dewy nights come, so do the plants thrive. In the absence of rain and dew, syringing late in the afternoon on fine days will prove very beneficial. Syringing would chill the plants if done in cold, dull weather.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Gladiolus Eldorado.—A variety of merit and distinction. The large, widely expanding flowers of soft canary yellow tone are rendered conspicuous by bold, irregular blotches of reddish crimson on the lower petals. We recall nothing so remarkably distinct and good. Exhibited by Messrs. James Kelway and Son, Langport.

Michauxia Tchihatcheffi.—A remarkable plant of the Bellflower Order, from Asia Minor, of somewhat difficult or at least uncertain cultivation.

NEMESIA MARSDEN JONES' STRAIN.

The white, horizontally disposed flowers are borne in a close spicate raceme, though branching freely at the base in good specimens. The woolly leaves are toothed, the barren rosettes lying almost prostrate on the ground. Shown by Miss Willmott, Great Warley.

Nemesia Marsden Jones' Strain.—In this case the award was made to a strain characterised by large flowers of red and crimson shades over a golden ground colour. In some the upper lobes of the corolla are almost wholly crimson, in others they are crimson, chequered with gold. A very beautiful race. From Mr. E. Marsden Jones, Malpas.

NEW ORCHIDS.

Three first-class certificates were awarded for novelties of unusual interest. Mr. J. Gurney Fowler of Brackenhurst, Pembury, Kent, showed *Miltonia vexillaria* Rev. W. Wilks, with immense pale pink flowers nearly five inches in depth and over three inches across. It was raised by crossing *M. v. gigantea* with *M. v. Queen Alexandra*. Mr. F. Montieth Ogilvie, The Shrubbery, Oxford, showed a magnificent variety of *Odontoglossum percultum* named King George; but the greatest triumph among new Orchids was the bigeneric hybrid *Odontonia Charlesworthii*, from Messrs. Charlesworth and Co. This is unquestionably the finest *Odontonia* yet raised, the lip being bright purple red and the petals deeper red. Parentage: *Odontoglossum Uro-Skinneri* × *Miltonia vexillaria*.

An award of merit was granted to *Brasso-Cattleya Ilene* The Dell Variety, shown by Baron Schröder, The Dell, Englefield Green.

The foregoing awards were made at the fortnightly meeting of the Royal Horticultural Society on July 14.

ROSE MAJESTIC.

This was one of the most fragrant of the gold medal Roses at the National Rose Society's summer show held recently in Regent's Park. As described in last week's issue, it is a Hybrid Tea of vigorous, upright habit, with stout, spiny stems. The large, well-formed flowers are of a glowing soft vermillion pink. It was shown by Messrs. William Paul and Son, Limited, Waltham Cross, Herts, and is quite an acquisition for either garden or decorative purposes.

A FEW GOOD FORCING ROSES.

NOW that Rose forcing is over, it may be useful to look back and form conclusions of what proved of most service during the winter and spring. Many old favourites are still unbeaten, but I can give the highest praise to the following from among our newer varieties:

THE NEW ROSE MAJESTIC.

Melody has jumped to the front as a reliable forcer, so much so as to already figure among the few varieties regularly grown for market purposes, which in itself is the best possible proof as a reliable one for early culture. This is one of the best pure saffron yellows we have, being very rich in the centre, with clear primrose yellow edges. The flowers are invariably carried bold and upright upon a stiff stem, open well, retain their exquisite form for a long time, are very freely produced and sweet-scented. This is also a grand Rose for the open air, particularly as a bedder. It is claimed to be mildew-proof, and has proved so with me, both under glass and outside, since its introduction in 1911.

Ophelia came from Waltham Cross a year later, and has taken a high position here. This is another splendid forcer and carries its flower well; free in every way, and also a good outdoor bedder. A clear salmon flesh centre shaded with rose, and altogether a great acquisition.

Lady Hillingdon is now by all generally known as a good forcer. It was recognised as such before its introduction, taking quite a front place among our market growers. It has good foliage and each flower is carried well; the colour is the most intense orange yellow while young, which it keeps better than most yellows. It has very long buds, and is one of the freest bloomers. It is likely to be one of the most extensively grown under glass, and is also much better in the open than was generally thought at its first introduction. It is indeed beautiful in the autumn.

Mme. Edouard Herriot has been exhibited well both last season and this. As a forcer it must be good, and cannot fail to prove a fine bedder. My own stock of plants are doing well, and where price is no great object I strongly advise a few being tried for winter forcing. Coral red, shaded with yellow and rosy scarlet. Not a full Rose, but very freely borne and opening well.

Sunburst is certainly one of the best of 1912. We seem to be minus the disappointment of pale-coloured flowers when forcing this variety. In the open it is not satisfactory until warm weather sets in, when it is among the best right up to the time of frost. A stout-petalled and beautifully carried bloom of clear orange yellow with a deeper centre, lasting well when cut young and retaining its colour. It is bound to become one of our most popular forcing varieties.

I am giving these notes early as a guide towards the selection and preparation of our best newer varieties for next winter's blooming, which should be taken in hand soon.

Uckfield.

A. P.

GLADIOLUS ELBORADO

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

The Early Vines.—Lateral growth may now be cut hard back, in order to expose the Vines to the sun, so that the wood may be thoroughly ripened. Examine the borders, and if necessary give a good soaking of water, previous to which a sprinkling of Thomson's Vine Manure may be applied.

Cucumber Plants for late autumn supplies should now be ready for planting. It is better to make several plantations during the season than to rely on plants which have become exhausted.

Melons.—The latest plantation of Melons may now be made, in order to produce ripe fruits in October. Plant 4 feet apart and secure the first batch of flowers.

Plants Under Glass.

Roman Hyacinths.—These are always welcome, and to have them early the bulbs should be potted with as little delay as possible. Do not make the soil too hard underneath the bulbs, but simply press them into the compost and make firm round them. After potting, they may be placed on a bed of ashes and covered with several inches of the same material, which should be passed through a fine sieve.

Poinsettias.—The earliest batch of plants can now receive their final shift into 6-inch or 7-inch pots, according to the state of the plants. Grow in a temperature of 70° and expose the plants to as much light as they will stand without flagging. Ventilation must be given to keep them from becoming too soft.

Salvia splendens.—Plants for winter flowering should now receive their final shift. Nine-inch pots will not be too large if the plants are growing freely. The soil may consist of three parts turfy loam and one part decayed horse-manure. Pot moderately firm and protect from heavy rain until the pots are well filled with roots, when they may be placed on a bed of ashes in the open garden until the weather becomes too cold at night.

The Flower Garden.

Pentstemons.—Some varieties are in full bloom, and should receive supports to keep them from injury by rough wind. Mrs. Fulford, a variety of recent introduction, is now throwing up strong spikes of rich red flowers of good substance and size. Stir the soil between the plants and give a top-dressing of decayed horse-manure with as little delay as possible. Liberal supplies of water may afterwards be given.

Gladioli.—These are making good, clean growth and pushing up their flower-spikes, which will require neat stakes to keep them in an upright position. Do not allow them to suffer from want of moisture at the roots, and, if dry weather sets in, a mulching of decayed manure will do much to keep them in a clean, healthy condition.

Sweet Peas.—As the flowers show signs of decay, they should be carefully removed from the plants before any seed-pods are formed, in order to prolong the flowering period as far into the autumn as possible, and with the same object in view frequent applications of manure-water may be given.

Spiræas.—*Astilbe palmata*, *A. Davidii*, *A. Queen Alexandra* and *A. Peach Blossom*, if planted in bold groups by the water's edge, present an imposing appearance; but unless the roots reach the water-level they must receive daily attention with the water-pot. They will also benefit by a mulching of some moisture-retaining material.

The Rock Garden.

Dianthi which are passing out of flower should be trimmed back, in order to produce stocky young shoots for propagation. *Dianthus alpinus*, a beautiful rock garden plant, may easily be increased in this way or by seeds, and should be planted in poor, moist soil, where it forms a dwarf, compact plant with flower-stems only a few inches long.

The Hardy Fruit Garden.

Apples, Pears and Plums are swelling fast, and trees carrying heavy crops require careful

thinning. For this purpose a pair of good scissors is the best implement. As this work proceeds, care must be taken to leave the fruits which are best placed with regard to sunshine. In the first place, all deformed fruits should be removed, leaving only such as will develop into good specimens and nothing beyond what can be brought to maturity without injuring the prospects for the following season. Many of the side growths may be shortened, in order to admit light and air to the middle of the trees and with a view to forming fruit-buds for another year. This shortening of the growths, if accomplished before this date, will sometimes cause new growths to break from the eyes, which are of no value and have to be cut away at a later date, thus defeating the object of forming fruit-buds.

The Kitchen Garden.

Turnips for Winter Supplies.—A good sowing of Turnip seed should be made now, and another in ten days' time. Allow 18 inches between the rows, as nothing is gained by overcrowding.

Spinach for Late Autumn Supplies may be sown at once, and for winter about the middle of August. Allow 18 inches between the rows for this crop, and thin out the seedlings to 4 inches apart as soon as large enough.

French Beans.—If cold pits are available, several plantations may be made during August for the supply of pods in October and November. The lights should be removed until cold weather sets in during the autumn.

Early Potatoes.—As soon as the skins are set, this crop should be lifted and stored for future use. The ground will then be available for Coleworts or other winter crops.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Runner Beans.—These are growing rapidly, and attention must be given to see that the vines are taking to their supports. If allowed to fall over, they get so entwined that it is next to impossible to do anything with them.

Mushrooms.—Preparations for a supply of Mushrooms in the autumn may now be made. Collect fresh horse-manure and have it placed in layers in a dry shed, where it should be turned each day. Meantime, opportunity can be taken to have the Mushroom-house thoroughly washed down and everything made ready for making a start.

Cucumbers.—Those growing in frames will now claim attention in the way of feeding and regulating the shoots. Endeavour to keep the foliage healthy, and cut the fruits regularly from the plants; otherwise, if allowed to mature, the plants soon show signs of exhaustion.

Lettuce and Endive should be thinned out to avoid crowding, and make another sowing of each for winter use. Where a sowing of Parsley was made at the beginning of June, the young plants ought to be ready for thinning. A number of these thinnings can be dibbled into frames; these will make nice plants before the winter, and will prove a very useful crop indeed.

The Flower Garden.

Layering Carnations.—In light, sandy soil it is sometimes not necessary to prepare it for this work, but on the whole it will pay to make up a light compost in which to put the layers. Should the weather be dry, give them a slight dewing in the evening. At the same time, my experience is that they root best in a dry season.

Hedges.—To keep hedges of Yew, Privet or Laurel in good condition, as well as from an ornamental point of view, they must be kept closely clipped. In the case of Laurels, it is most important to remember that they should never be trimmed with the shears, but always with a knife. It certainly takes much longer to do the work, but they look much better when finished, and there is no doubt it is better for the hedge.

Anchusas.—As the first flowers will be almost over, the flower-stems should be shortened back to where the new growths are appearing. These new growths will in a favourable season send up some nice flower shoots late in the autumn, which will give an added beauty to the herbaceous border and will associate well with the prevailing yellows of that season.

Lavender.—Where the flowers of this fine old-fashioned plant are required for household purposes, they should now be ready for harvesting. In this connection it is important to remember that they must be gathered before they are fully expanded. Tie them in small bunches and place them in a cool house, on a shelf which has previously been covered with paper, until they are perfectly dry.

Violas.—In a great many districts Viola cuttings will be difficult to obtain owing to the drought experienced lately. There is still time, however, to save the situation by going over the plants and removing all faded flowers. Give the plants a good soaking at the roots two or three times.

Plants Under Glass.

Deciduous Calanthes.—These should now be well rooted, and will require to be more liberally treated in the way of watering, and, if judiciously applied, a little weak liquid manure occasionally. But much damage may be done to the young growths if water is allowed to collect at the base. This must be guarded against at all costs.

Ferns for Bowls.—During the past year or two there has been an increasing demand for ornamental bowls filled with bulbs and small Pterises for blooming indoors during the winter months. For this purpose pot up the required number at once into 3-inch pots. The varieties *Pteris major* and *P. Wimsettii* are especially suited for this work. In most places no difficulty will be experienced in securing a sufficient number of plants from self-sown spores; if not, young plants can be purchased very cheaply from Fern-growers.

Stocks.—Some time ago I remarked on the excellence of these plants for providing a supply of cut flowers in the spring. The first sowing should be made without delay. The varieties I have found most suited for this work are *Princess Alice*, *Beauty of Nice* and, as a charming companion, *Emperor* (*Augusta Victoria*). Sow one or two seeds in small pots and place them in a cold frame, eventually thinning them to one plant in each pot, and from the very outset avoid anything in the nature of coddling. Pot on as required, and remember that they will amply compensate for a little extra care and attention.

The Hardy Fruit Garden.

Peaches.—The trees may now be gone over and all superfluous shoots shortened back. The growths that are to furnish the tree should be so arranged that the fruits will be exposed to the sun. It is surprising what a delightful hue Peaches in the open take on when exposed to the full glare of the sun; not only so, but the flavour is also much improved thereby.

Apples.—Trees which are carrying heavy crops must be assisted by frequent doses of liquid manure, and have a good mulching of manure placed over the roots.

Fruits Under Glass.

Vines.—Houses in which Grapes are beginning to colour should have air admitted top and bottom during the night, and at the same time keep up a little fire-heat. In order to prevent the inside border becoming dry, give a mulch of manure from a spent Mushroom-bed, or, failing that, meadow hay would answer the same purpose. Continue to remove lateral growths as they appear, and every means should be taken to keep red spider in check.

Tomatoes.—Where a supply of Tomatoes is desired during the winter, the seed should be sown without delay. As soon as the young seedlings appear, they must be placed close to the roof glass to prevent them becoming drawn. When the seedlings have been potted, place them in a cool house where they will have full exposure to light and air.

(Head-gardener to the Marquis of Linlithgow.)
Hoptoun Gardens, South Queensferry, N.B.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SOLDANELLAS (M. W. S.).—It is obviously an instance of the development of latent flower-buds—a not unusual circumstance with many plants. In fruit trees, for example, both fruit and flowers are occasionally seen on the same spray, and your Soldanella with "ripe seed" (fruit) and "fresh flowers on the same stalk" is identical in principle. We did not understand that this was so from your former communication.

HEUCHERAS NOT FLOWERING (W. K.).—Have you any particular variety in mind? The only one having any pretensions to shy flowering is *H. sanguinea* in certain districts and in cold clay soils. There are varieties of it that are much freer flowering. All the plants grow freely in sandy loam, but, in addition, the one above referred to prefers also a rather warm, well-drained soil and situation. The forms of *H. gracillima* and the hybrids between this and the first named are proverbial for their free flowering; hence we imagine you must be dealing with a poor type of the original. The best methods of increase are by seeds and by division of the crown tufts in spring. The plants divide quite readily, and if firmly replanted in rich soil soon become established again.

PLANTS FOR BANK IN WOOD (A. H. R.).—You have obviously a good opportunity for some natural effects, though just what would be the best plants could only be accurately determined on the spot. In any case, we think you cannot err in planting the Winter Heath (*Erica carnea*) for winter and early spring, with also the taller-growing Portuguese Heath (*Erica lusitanica*) for later effect. Almost all the *Lastreas*, *Polypodiums* and *Athyriums* would do well in the sandy soil, provided also that the conditions are cool and the rooting medium fairly deep. We should hesitate before planting *Azaleas*, unless it was in or near woodland scenes. Almost all the fine-leaved Japanese Maples would do well in sandy, loamy soils, and you may select at will from golden, crimson and green leaved sorts, all of which are beautiful. The finer colour effects these afford are only secured by exposure to full light; shade is detrimental thereto. For the rest, you might plant a few of the more graceful Bamboos near the water, also *Spiraeas*, *Astilbes* and *Eulalias*. On the rough bank, if you discourage the Bracken and other wild material, many things might be grown. Double Gorse and some of the Brooms would be effective, and Foxgloves might prove very charming. It would require a more intimate knowledge of the spot and your own intentions in the direction of beautifying it to give a more definite reply.

TREES AND SHRUBS.

OLD HEATHS (A. K. M.).—The best thing to do with your old *Ericas* would be to destroy those which have outgrown their positions and have become bare towards the base. Such plants, if cut back, would not start away well, neither would they bear transplanting well. By starting again with young plants your bed would be far more satisfactory than at present. The best winter Heaths for your district are *Erica mediterranea* hybrids,

E. carnea and *E. carnea alba*; for spring, *E. mediterranea*; for summer, *E. cinerea* and varieties, *E. Tetralix* and *E. stricta*; and for autumn, *E. ciliaris* and variety *mawana*, *E. vagans* and varieties, *Daboecia polifolia*, and *Calluna vulgaris* and varieties.

DOUBLE LILACS AND SEED (J. G. N.).—It is not usual for double flowers to produce seeds, but in an inflorescence of usually double flowers some may be single or partly so, the reproductive organs being perfect. In such cases seeds may be produced, or, in some instances, the ovaries may swell up without maturing seeds. The fruits of the Lilac heads similar to the one sent for examination will not mature after the flower-heads have been removed, and if kept they will be of no use.

A WINTER-FLOWERING CLIMBER (T. W.).—If you wish for a winter-flowering climber, you cannot do better than select *Jasminum nudiflorum*, for it blossoms for about two months from December onwards. If, however, you prefer a plant to bloom in May, use *Clematis montana rubens*. It is a vigorous kind, which does not suffer from disease, as many kinds do, and it blossoms freely. If you obtain a plant in a pot, it may be planted any time; otherwise in October. You may plant Ivy against your wall in October.

ROSE GARDEN.

PINK GLOIRE DE DIJON (H. G.).—Yes; there is a Rose named Kaiserin Friedrich that bears flowers much like Gloire de Dijon, only that they are shaded with pink. If, as you say, one shoot bears flowers of a good pink colour, you should bud from this shoot. Ask some local gardener to bud it for you on to a Briar, or even on to another Rose. You could put cuttings in also from the half-ripened wood. Put the cuttings under a hand-light in the shade, using nice sandy soil to place them in.

TWELVE FRAGRANT AND FREE-BLOOMING ROSES (Pauvret).—An excellent selection would be as follows: Mme. Abel Chatenay, Mme. Ravary, Pharisier, General Macarthur, Duchess of Wellington, Lieutenant Chauré, Liberty, Laurent Carle, Viscountess Folkestone, Mrs. John Laing, Mrs. Walter Easlea and Hugh Dickson.

FRUIT GARDEN.

CANKER IN APPLE TREE (Gera).—Yes; your Apple is badly attacked by canker. The affected portions should be cut out as soon as possible and the wounds painted over with lead paint or tar, otherwise the disease is bound to spread. You will find a long article dealing with this disease in a recent issue.

PEACH MILDEW (H. C. N.).—The Peach is attacked by Peach mildew. Keep the house well ventilated, and, if the disease spreads, spray with a solution of potassium sulphide, at the rate of 1oz. to four gallons of water, in the evening. The Rose has apparently suffered a check during its development, and has subsequently grown on.

FIG TREE CASTING ITS FRUIT (S. R. J.).—We think that the tree must now be at the flowering stage. If this is so, it is nothing unusual for a tree to cast a few fruits at this time. If the tree casts all its fruit one year after another, then there must be something radically wrong in your mode of culture. Generally the failure arises from the fact of the tree being too heavily furnished with branches and foliage during the summer. You must remember that the fruit of next year is borne on the branches of this year's growth. If this is not properly developed and nurtured by exposure to all sunshine, light and air possible, then it cannot bear fruit. If your tree is at all overcrowded with branches of this year's growth, do not hesitate a day in cutting out the weakest to give the others a better chance.

GRAPES BADLY SHANKED (Thaley Park).—The Grapes were a rotted pulp when received, and the letter steeped in the same, making it difficult to decipher. Yours is a bad case of shanking—caused, we think, by serious root trouble. How this has been brought about it is difficult for us to know, but most likely by applying too heavy doses of artificial manure. These manures are valuable and indispensable helps when applied with discretion and knowledge in the growth of Grapes; but when applied in too heavy dressings, then they do incalculable harm. We believe that you will find many of the roots have collapsed, and are more or less dead. To bring the Vines round, your best plan will be to lift the roots to within 2 feet of the wall of the vinery and thoroughly examine them, cutting away the weak and impaired, and relaying the rest in a new border made of best Vine-growing compost. You will soon get your Vines round by doing this, and in no other way.

ABOUT APPLE TREES (Shirley).—The Apple foliage and fruit are both attacked by aphides, and it is these which are causing the red coloration on both. Spraying with quassia and soft soap, with nicotine, or with one of the proprietary sprays that are so numerous, and many of which are good, in early spring would reduce the attack markedly. The shoot of Apple Mannington's Pearmain is attacked by Apple mildew, and no amount of spraying is likely to cause its disappearance, as the fungus is perennial in the tissues of the Apple shoots. The only method to adopt is to prune away and burn the affected shoots in early spring as soon as they can be seen. Spraying for Codlin moth is not likely to be an effective preventive unless a food poison spray is used and sprayed forcibly on the fruit so that it enters the eye of the Apple. Quassia and nicotine are not food poisons; the best is lead arsenate; lead acetate should not be used. Codlin moth is rather an uncommon pest in this country at the present time, and the depredations of the Apple sawfly are often mistaken for it. Spraying may check this to a slight extent, but

the best check is imposed by the prompt collection of fallen fruits and their destruction by fire.

MISCELLANEOUS.

INJURY TO SWEET PEAS (A. R.).—The material sent is insufficient to enable us to diagnose the disease. Please send a complete plant.

GRUBS FOR IDENTIFICATION (A. F.).—Neither of the grubs sent is harmful. The active one is the larva of one of the ground beetles, and feeds on other insects. The other is the larva of a two-winged fly, which feeds on vegetable refuse.

CABBAGE ROOT MAGGOT (Mrs. E.).—The little whitish maggot is the Cabbage root maggot, which is often very troublesome through attacking Cabbages, Cauliflowers, and other plants belonging to the Cabbage family. The best thing to do to protect the plants from the maggot is to dust sand, damped with paraffin, along the rows. This will help to keep the parent fly from laying her eggs, and so prevent the attack of the pest. The other grub is the wireworm, and for this constant hoeing is necessary. Where there are plants which need protection in wireworm-infested ground, a piece of Potato or Carrot may be buried with a stick marking the spot. Examine it at frequent intervals and destroy the captures.

NAMES OF PLANTS.—W. J. H.—Roses: 1, fallen; 2, Mme. d'Arblay; 3, Joseph Lamy; 4, Rosa lucida plena; 5, Paul Transon; 6, Mrs. Waterer.—**E. W. N.**—Both specimens of *Centranthus ruber* are typical examples of the species. It is not unusual for some variation of colour to occur. Both shades are often seen. The *Rhododendron* is *R. azaleoides*, a hybrid between an evergreen *Rhododendron* and a deciduous species of *Azalea*.—**H. Ongar.**—Roses: 1, Margaret Dickson; 2, Baroness Rothschild; 3, Rev. Alan Cheales.—**A. M. B., Longformacus.**—Rose *Euphrosyne*, *Salvia* *Grahamii* and *Serapias Lingua*.—**Mrs. D., Salisbury.**—1, *Campanula rapunculoides*; 2, *C. alliariaefolia*; 3, *C. linifolia*.—**N. Y.**—1, *Galium verum*; 2, *Selaginella Braunii*; 3, *Selaginella* species, cannot identify, too scrappy; 4, *Helxine Solierii*; 5, *Sedum rupestre*; 6, *S. acre*.—**Wild Flowers.**—1, *Hyoscyamus niger* (Henbane); 2, *Erythraea Centaureum* (Centaury); 3, *Ononis spinosa*; 4, *Galium Mollugo*; 5, *Senecio Jacobaea*; 6, *Agrimonia Eupatoria*; 7, *Lotus uliginosus*; 8, *Hypericum quadrangulare*.—**Burton.**—*Monarda didyma*.—**T. M., Bridport.**—A garden escape, native of North America.—**E. M. H.**—*Spiraea arborescens*.—**S. H. B.**—*Carlina acaulis caulescens*.—**P. A. Sturge.**—1, *Verbascum Lychnites*; 2 and 3, two seedling forms of *V. densiflorum*; 4, *V. Chaixii*. Specimens of *Verbascums* should include mature leaf in order to identify with any certainty.—**B. Cummings.**—1, *Sedum rupestre*; 2, *S. reflexum*; 3, *S. hybridum*; 4, *S. roseum*; 5, *S. Anacamposeros*; 6 and 7, forms of *S. spurium*; 8, *S. album*; 9, *Arenaria montana*.—**Constant Reader.**—The yellow flower is *Lysimachia thyrsiflora*; the Rose Fellenberg.—**Mac, Deal, Kent.**—Roses: 1, Newport Fairy; 2, Excelsa.

SOCIETIES.

NATIONAL SWEET PEA SOCIETY'S SHOW.

THE fourteenth annual exhibition in connection with the above society was held in the Royal Horticultural Hall, Vincent Square, Westminster, on Thursday, the 16th inst. On account of the dry weather and the rather late date of the show, a number of big seed firms, notably Messrs. Sutton and Sons, Messrs. J. Carter and Co., Mr. W. J. Unwin and Messrs. R. H. Bath, Limited, were unable to stage their customary groups. Taking all things into consideration, however, the show was a very good one indeed, and attracted a large number of visitors during the afternoon. The new secretary, Mr. H. D. Tigwell, had made excellent arrangements.

NON-COMPETITIVE GROUPS.

These, as usual, were arranged around the walls of the hall, and constituted an ideal setting to the gems of the moment. There were some fourteen or fifteen of these groups, which were virtually a show in themselves.

Taking the groups in order, we first came to that of Messrs. E. W. King and Co., Coggeshall, Essex, who arranged a collection of the flowers in considerable variety and beauty. It would have been better, we think, had the flowers been staged lower down. The beauty of the Sweet Pea cannot be estimated at 10 feet high. The collection was quite a representative one.

Robert Sydenham, Limited, Birmingham, had a prettily arranged group, using rustic and other vases of an artistic nature. The arches of Princess Mary (deep blue) and R. F. Felton (reddish mauve) were very nice. Robert Sydenham (orange scarlet), Lillian (pink) and Barbara (pale orange) were also excellent.

Messrs. Bide's (Farnham) arrangement consisted of rather high-placed arches ornamented by *Smilax*, with occasional vases of Sweet Peas. Lower down, vases of the flowers ornamented with *Asparagus Sprengeri* were the rule. Of these Princess Mary (blue), Mrs. Breadmore (cream) and Phyllis Bide (scarlet) were the best.

Hobbies, Limited, Dereham, also arranged arches of the flowers with vases below. The latter contained some excellent examples, Marjorie Linzee (rose cerise), Thomas Stevenson (orange), Mrs. Hugh Wormald (pluk and cream) and Dorothy (rose and mauve) being good.

Rural floral decorations were arranged by Mr. Fred W. Wood, Waltham, S.E.

Messrs. Jarman and Co., Chard, displayed a representative lot of the flowers of good quality, R. F. Felton, Elsie Herbert, Lavender G. Herbert and Hercules (pink)

being good. This group was ornamented by sprays of the fragrant *Humex elegans*.

Messrs. Dickson, Belfast, had some excellent flowers in a rather high-placed arrangement. Their vases of Hilary Christy (rose and orange), Dobbie's Cream, Maud Holmes (of which pillars were formed), Seamew (pale mauve), Barbara (orange) and Orchid (mauve and rose) were very fine. Blue Picotee, King White and Thomas Stevenson were also notable examples in a fine lot.

Mr. James Box, Hayward's Heath, had an excellent arrangement of the flowers in conjunction with high quality. Against a background of velvet three bold vases were arranged with trails of Smilax and light Grasses. The effect was decidedly good, the grouping being light, yet telling. James Box, Elfrida Pearson, Lindfield Grey, Afterglow, Edna May Improved and Dobbie's Cream were very fine.

Messrs. C. C. Morse and Co., San Francisco, California, showed the new Sweet Pea Margaret Atlee, a delightful flower in pale and rose pink shades. A superb lot of the flowers was displayed.

Messrs. Dobbie (Edinburgh) staged, as usual, a particularly fine lot against a background of velvet festooned by Smilax. The flowers were very fine. The bolder vases we thought a little too massively arranged. Dobbie's Cream, Mrs. Heslington, Alfred Watkins (lavender), Queen of Norway (rosy mauve), Red Star, Nora Unwin and Thomas Stevenson were the finer lots in a very telling exhibit.

Mr. Robert Bolton, Carnforth, had a nice arrangement of flowers opposed to a rather weak pale green background. The flowers, too, were less fine than we are accustomed to see from this exhibitor.

Mr. H. J. Damerem, Hayling Island, Hants, also contributed a small group of these flowers.

COMPETITIVE CLASSES.

In Class 1, for eighteen bunches, distinct, three competitors came to the front, the first prize, the Sutton Cup, going to Mr. A. E. Usher, Ranston Gardens, Blandford, who staged an admirable lot of flowers. His collection comprised Maud Holmes (crimson), May Campbell (rose and cream), Mrs. Cuthbertson (apple blossom rose), Prince George (rose and salmon), Edith Taylor (rose), Lavender G. Herbert, Barbara (orange), Dobbie's Cream, Mark's Tey (red and violet), W. P. Wright (lavender), Princess Victoria (pink), White Queen, Thomas Stevenson (orange), Edrom Beauty (orange and rose), Agricola (pale pink) and King Manoel (maroon). A magnificent set of varieties. Second, Mr. E. R. James, gardener to Lord North, Wroxton Abbey, Banbury; third, Mr. J. Stokes, Lyme Regis.

For the Henry Eckford Memorial Cup, twelve bunches distinct, eight competitors contested, the premier award going to Mrs. A. V. Macnamara, Ennistymon, County Clare, Ireland, whose excellent group was made up of Orange Perfection, Mrs. Harcastle Sykes, Sunproof Crimson, New Marquis (purple), Orchid (rosy mauve), Illuminator (scarlet), Thomas Stevenson (scarlet orange), Elsie Herbert (pink and white), Hercules (rose), Audrey Crier, Wenvoe Castle (violet and rose) and King Manoel. Second, Mr. T. Stevenson, gardener to Mr. E. G. Mocatta, Woburn Place, Addlestone, whose admirable lot was made up of Lavender G. Herbert, Thomas Stevenson, King Manoel, R. F. Felton, Elsie Herbert, Hercules, Orange Perfection, New Marquis, Edith Taylor, William Cuthbertson, King Edward Spencer and Mrs. C. W. Bredmore. This was a splendid exhibit, a very close second to the excellent collection from Ireland. Third, Miss Scrivens, Bexhill-on-Sea.

In Class 3, for six distinct bunches selected from varieties put into commerce since autumn, 1912, only four lots were staged, the first prize going to Mr. T. Jones, Ruabon, whose collection comprised Illuminator, King White, Agricola (pink), Lavender George Herbert, Mark's Tey and Thomas Stevenson. The varieties were shown in his inimitable style. Second, Mr. E. Cowdy, Loughgall, County Armagh.

Class 4, for three bunches, was only poorly represented. Mr. Lewis S. Peters, St. Austell, Cornwall, had Lilian, Hercules and Gladys Burt, all very good.

In the open classification class, Class 5, for a collection of eighteen varieties, five competitors put up excellent groups, the premier prize going to Mr. E. Keith, gardener to Sir G. O. Trevelyan, Bart., Wallington Hall, Cambs, whose best were Barbara, Dobbie's Cream, Hercules, Mrs. Hugh Dickson, Mark's Tey, Agricola and R. F. Felton. The flowers generally were not of high excellence. Second, Mr. A. Shkelton, Forde Abbey Gardens, Chard.

For twelve bunches of Sweet Peas, distinct, open to all, five exhibitors staged collections of the flower, Mrs. A. V. Macnamara, County Clare, Ireland, leading the way with a fine assortment, Radiance, Barbara, Margaret Atlee, Mrs. E. Cowdy, Mrs. C. W. Bredmore, Lavender George Herbert, Wedgwood, Mrs. Harcastle Sykes, Sunproof Crimson, King White and Rosabelle comprising the collection; an admirable set, well coloured and handsome spikes. Second prize, Miss Scrivens, Millfield, Bexhill-on-Sea, who also had a lovely lot of flowers.

For twelve bunches of Sweet Peas of lavender, cream pink, scarlet and orange, only one exhibitor, Mr. A. E. Usher, staged, and was awarded first prize.

In Class 8, for eighteen bunches of Sweet Peas suited to garden decoration, two exhibitors staged collections, the first prize going to Mr. A. E. Usher, gardener to Sir Randolph Baker, Bart., Blandford, whose excellent group contained Thomas Stevenson, Clara Curtis, Lavender George Herbert, W. P. Wright, Duplex Spencer and Tennant Spencer. Second, Mr. J. T. Tigwell, Greenford, Middlesex.

For the E. W. King Challenge Cup, for twelve waved varieties, distinct, there was a strong competition, eight exhibitors staging collection. The first prize went to

Mr. E. Cowdy, Loughgall, County Armagh, whose best were Lavender George Herbert, Mary Unwin, Mark's Tey, R. F. Felton and Mrs. H. Sykes. Second, Mr. Lewis Peters, St. Austell, Cornwall.

DISTRICT CLASSES (TRADE EXCLUDED).

These were divided into two groups, the London and Scottish classes exhibiting six bunches each; the Irish, Welsh, Northern Counties, Western, Eastern, Midland and Southern Counties exhibiting nine bunches each.

In the London class, Mr. G. M. Morewood, Windmill Road, South Ealing, was first, having Maud Holmes and Thomas Stevenson as his best. There were five competitors.

In the Scottish class, Mr. J. A. Ginger, Forres, N.B., took first place, having superb vases of Margaret Atlee and Lavender George Herbert.

In the Irish class, for nine, only two competitors faced the judges, the first prize going to Mrs. A. V. Macnamara, Ennistymon House, County Clare, whose strong collection was made up of Mrs. W. J. Unwin, Radiance, Edrom Beauty, Maud Holmes and Helen Williams, among others. Mr. E. Cowdy was second.

In the Welsh classes, Mr. T. Jones led the way, his vases of Margaret Atlee, Dobbie's Cream, Melba, Elfrida Pearson and Hercules being particularly fine. Mr. L. Webb, Welshpool, was second.

In the Northern Counties class, Mr. E. Keith was first with an admirable lot.

In the Western classes, Mr. A. E. Usher took the lead with a superb lot.

In the Eastern Counties class, Mrs. A. Hitchcock, Tiptree, Essex, took premier place. There were ten competitors in this class, the flowers being very good.

In the Midland Counties class only two competitors staged, the first prize going to Mr. E. R. James, Wroxton Abbey Gardens, Banbury, for a very fine lot.

In the Southern Counties class, for which the first prize was a piece of plate, value three guineas, offered by the Proprietors of THE GARDEN, there were six competitors, the first prize being awarded to an admirable lot from Miss Scrivens, Millfield, Bexhill-on-Sea, whose collection of nine comprised Thomas Stevenson, Hercules, New Marquis, King Manoel, King White, Edith Taylor, Audrey Crier, Maud Holmes and Barbara. Second, Mr. T. Stevenson, gardener to E. G. Mocatta, Esq., Addlestone, who also staged a very fine collection.

In the Burpee Cup class, for a display of waved Sweet Peas, to be arranged on a table space 8 feet by 3 feet, only one competitor, Mr. T. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, came to the front, the exhibit, in our opinion, being rather crowded. The best vase was Thomas Stevenson. New Marquis, King Manoel, Marjorie Linzee, Prince George and Lavender George Herbert were also good.

For the Horace Wright Challenge Cup, twelve bunches, distinct, five competitors staged collections, the premier award going to Mr. W. H. Holloway, Port Hill, Shrewsbury, whose dozen was made up of Thomas Stevenson, May Campbell, Elsie Herbert, Ivanhoe (blue), Clara Curtis, Rosabelle, Agricola, King White, Mark's Tey, King Manoel, Hercules and Sunproof Crimson. Mr. C. R. Jaggs, Vicarage Cottage, Hertford Heath, was second.

For the Walter Voss Challenge Cup, for six distinct varieties, to represent six different colour classes, five competitors staged collections, the premier award going to Mr. W. H. Holloway, Portyville, Port Hill, Shrewsbury. His set was Lavender G. Herbert, Agricola, Hercules, Elfrida Pearson, King Manoel and Rosabelle. Mr. C. R. Jaggs was second.

NEW SEEDLING VARIETIES.

Fiery Cross (vivid scarlet cerise), raised by Mr. A. Malcolm, Duns, to be introduced by Messrs. W. Atlee Burpee and Co., was given an award of merit and reserved for the silver medal, 1915.

Royal Purple and Jean Ireland (pink and cream), both from Messrs. Dobbie and Co., also received awards of merit. These had been grown at the Society's trials, and the awards were made by the floral committee.

TABLE DECORATIONS.

In Class 36, for a table decoration 3 feet in diameter, there were fourteen competitors, the first prize deservedly going to an exquisitely beautiful and tasteful arrangement from Mrs. A. G. Gentle, Little Gaddesden, Berkhamsted, who employed cream-coloured Sweet Peas in conjunction with the lightest of grasses, and touches of bronzy foliage and Acacia cultriformis. Second, Mrs. Alex. Robinson, Carshalton.

In Class 37, for an epergne or stand, there were fifteen exhibitors, Mrs. A. D. Ruff being awarded first prize.

NATIONAL CARNATION AND PICOTEE SOCIETY.

THE annual exhibition of the Southern Section of this society was held at the Royal Horticultural Hall on July 17. The show was a comparatively small one, its better phase being the long-stemmed flowers shown in vases. Those shown on cards, many distorted beyond measure, failed to arouse any enthusiasm.

For a stand of twelve Carnations on cards, bizarres and flakes, Mr. H. R. Taylor, Cheam, was first, having Opal, Mrs. L. Lord, Gordon Lewis and George Morel among others. Mr. J. Douglas was second. There were three competitors.

For twelve Carnations, selfs, Mr. Charles Blick, Hayes, Kent, was first, having Daffodil, Rosy Morn, Mimosa, The Chartist, Blondel, Bookham White, Fujiyama (red), Ashantee (crimson) and Mrs. Eric Hambro (white). Mr. James Douglas was second also in this class, his best flowers being Daffodil and Mrs. G. Marshall (crimson). Only two stands were set up.

For a stand of twelve Carnation blooms on cards, fancies, dissimilar varieties, there were three competitors, Mr. J. Douglas being placed first. In our opinion the stand of these from Mr. C. Blick, Hayes, Kent, who was placed second, contained a much weightier lot of blooms. Mr. Blick's Skirmisher was a grand flower. The same variety in Mr. Douglas' lot was in a state of collapse at 11 a.m. The latter's best flowers were Lord Steyne, Edenside and Linkman. Mr. Blick staged excellent Linkman, Forester, Donald McDonald and Mrs. Leo Hunter.

For a stand of twelve Picotees there were three competitors. Mr. H. R. Taylor, Cheam, was first; second, Mr. Douglas; third, Mr. Blick.

For twelve yellow-ground Picotees on cards, Mr. Douglas had the best lot, Mr. Taylor and Mr. Blick occupying second and third places respectively.

For four varieties of Carnations, selfs, three blooms of each, in vases, there were four entrants, Mr. J. Douglas occupying the first place with Basuto (crimson), Daffodil (yellow), Bookham White, and Cardinal (scarlet). Mr. H. Lakeman was second with good Bookham White and Daffodil. Mr. C. Blick was third.

For four fancies, shown in the same way, Mr. Douglas was again first, having Pasquin, Lord Steyne, Linkman and A. B. Stewart. Mr. Lakeman was second with a capital lot of flowers, having Father O'Flynn, Pasquin, Linkman and Lord Steyn. Mr. C. Blick was third with Cyclops, Skirmisher, Meduse and Linkman.

For four white-ground fancies, in vases, Mr. Douglas was first with a good lot, of which Henry Brett, Minnie, Mrs. P. D. Owen and Othello were prominent. Mr. C. Blick, who was second, had Herbert Newman, The Nizam, The Bride and Lass of Gowrie.

In the yellow-ground Picotee class, four varieties, three blooms of each, in vases, Mr. J. Douglas was again in the leading place.

For nine distinct varieties, selfs, fancies and yellow-ground Picotees, three blooms of each, Mr. J. Douglas was in the first place with a moderately strong lot, his best being Czar, Bookham White, Pasquin, Edenside and Elizabeth Shiffner. Mr. C. Blick was second with excellent examples of Daffodil, Forester and Linkman.

In the white-flowered class, one variety only, Mr. W. H. Paton, Moseley, was first with Bookham White.

In the dark red or maroon selfs Miss Shiffner was first with Mrs. G. Marshall (crimson).

In that for yellow selfs, three blooms, one variety, Mr. R. Morton, Woodside Park, was first with excellent Daffodil, this variety being favoured by seven out of nine competitors.

In the scarlet self class Mr. G. D. Ford was first in a collection of six with Fujiyama.

For three terra-cotta selfs, three out of four exhibitors had Elizabeth Shiffner, Miss Shiffner, Lewes, being first.

For six distinct varieties, selfs, fancies and yellow-ground Picotees, Mr. W. H. Paton, Moseley, was a good first, having Lord Steyne, John Knox (maroon), Margaret Lennox, Edenside, Rosy Morn and John Ruskin. There were four competitors, Mr. J. Fairlie, Acton, W., coming second with a nice lot of flowers.

For nine blooms, buff or terra-cotta selfs, one variety only, Miss Shiffner was first with Elizabeth Shiffner; three of four exhibitors showing this excellent variety.

Mr. J. Douglas was the only exhibitor in the class for other selfs, showing Purple Emperor and taking first prize. This exhibitor was also in the premier position in the classes for nine white, crimson, yellow and scarlet selfs, having Bookham White, Mrs. G. Marshall, Daffodil and Fujiyama respectively.

Good non-competitive exhibits of Carnations were staged by Mr. Douglas, Mr. St. John, Mr. D. B. Payne, Mr. Lakeman, Thornton Heath; and Messrs. Phillips and Taylor, Bracknell.

ROYAL HORTICULTURAL SOCIETY.

HERBACEOUS flowers were admirably shown at the fortnightly meeting of the above society on July 14. Phloxes and Gladioli were conspicuous among hardy flowers, while Roses, Sweet Peas and border Carnations were alike well represented. Some excellent fruit, both indoor and from the open, was also on view; but the show was not well attended, which, however, is not unusual during the month of July.

FRUIT AND VEGETABLE COMMITTEE.

Present: J. Cheal, Esq. (chairman), and Messrs. J. Willard, A. Grubb, A. Bullock, G. Kelf, W. Pope, H. J. Wright, O. Thomas, C. G. A. Nix and J. Davis.

A collection of bush and pot fruit shown by Maldwin Drummond, Esq., Cadland Park, Southampton (gardener, Mr. L. Smith), calls for special mention. In addition to Apples, Pears and Plums on well-cropped trees, there were a great many dishes of Strawberries, Currants (red, black and white), Raspberries, Cherries, Peaches, Melons, Figs, Nectarines and Gooseberries; while the Grapes Cannon Hall Muscat and Black Hamburgh were also shown. Silver-gilt Banksian medal.

A collection of twelve dishes of hardy fruits was shown by Eric Hambro, Esq., Pickhurst Mead, Hayes, Kent (gardener, Mr. Claud Davis). The best dishes included Currants Black Champion, White Dutch and Red Dutch, Strawberries Laxton's Latest of All and Eleanor, Gooseberries Speedwell and Gage Berry, and Plum Golden Drop. Bronze Knightian medal.

Apricots formed the chief feature of a collection of fruits in pots shown by Messrs. William Paul and Son, Limited, Waltham Cross. Of the Apricots shown we noticed the varieties Moor Park, Hemskirk, Peach, Domayan and Blenheim. Moor Park is probably the best of all, and it is interesting to note that it has been in cultivation for centuries. Silver Knightian medal.

THE GARDEN.

No. 2228.—Vol. LXXVIII.

AUGUST 1, 1914.

NOTES OF THE WEEK.

Our Garden Planning Competition.—We would remind all those who are entering our competition for planning and planting the little garden that completed designs must be sent in not later than September 1. All competitors should carefully read the rules published in our issue dated May 16, and also the replies to queries in our issue for June 20. The rules can be had by sending 1½d. in stamps to the Editor. All envelopes containing letters relating to the competition should be plainly marked "Planning Competition."

Rose Gustave Regis.—For growing as a large bush or rather low pillar there are few better Roses than this Hybrid Tea. It has a vigorous habit, and flowers freely when once established. The bush shown in the illustration is over five feet high, and has been in its present position three summers. The long, beautifully shaped buds are nankeen yellow in colour, this fading to cream as the blooms expand, when they are only semi-double. It is a splendid garden Rose, and one of the best varieties for button-holes. It was raised by M. Pernet-Ducher, and put into commerce in 1890.

A Raspberry Fraud.—During the last few weeks Loganberries have been freely sold in many fruiterers' shops for Raspberries. Although the Loganberry is a good and useful fruit, it is much inferior to the Raspberry, and as the same prices are being charged, the substitution can only be characterised as a fraud. Fortunately, it is not difficult to tell one fruit from the other. In the Loganberry there is a hard central core, which cannot be removed when the fruit is gathered; but in the Raspberry the fruit, unless gathered for dessert or exhibition, is pulled away from the core, and is therefore hollow. The Loganberry is also usually considerably larger than the Raspberry, and those who desire and pay for the latter should be fully on their guard.

A Pretty Floral Combination.—We were attracted the other day by a group of the beautiful scarlet dwarf Delphinium nudicaule growing in the rockery, among which had been planted the white Butterfly Viola (*Viola Papilio alba*)

raised from seed sown in the spring. Perhaps some may think it was rather too formal for the rock garden, but no one could deny how effective the combination looked. Both are readily raised from seeds and are also suitable for the border.

A Good Autumn Rock Garden Plant.—One of the most suitable subjects for autumn

soon makes good plants; or it may be readily increased from cuttings or by division.

Shirley Poppies with Blue Tints.—Through the courtesy of Messrs. James Carter and Co., who sent out the seeds last spring with the reservation that they did not accept any responsibility for the raiser's description, we have been growing some of Mr. Luther Burbank's "blue" Shirley

Poppies. Although the colour of these is far removed from that of the Gentian or the clouds of a summer sky, there is undoubtedly some suggestion of blue. The best we have had has been a sort of smoke blue colour, which is not particularly pleasing.

Public Rose Gardens in America.—Public Rose gardens, we learn from the *Florists' Exchange*, are being planned and planted in many places in the United States of America, and our contemporary puts forward a plea on behalf of the Roses for generous treatment. At Elizabeth Park, Hartford, Connecticut, where the first of the public Rose gardens was formed in that country, they have an excellent plan for determining the value of new varieties. Before a novelty is planted in quantity in the Rose garden proper it has to undergo a test in a garden specially reserved for the purpose. We hope the day is not far distant when novelties in this country will have to undergo some test of their capabilities before receiving awards from the National Rose Society.

The Wig or Smoke Tree.—At the present time, and for some weeks to come, one of the most striking of hardy shrubs in gardens will be *Rhus Cotinus*, the Venetian Sumach, or the Wig or Smoke Tree, so called on account of its feathery filaments. These small, thread-like filaments are really flower-stalks, a good proportion of which, however, have never borne a flower, but are clothed with numerous silky hairs that give the entire panicle the curious fluffy appearance

that is so characteristic. The shrub attains a height of from 6 feet to 8 feet, with a sturdy habit. It is a native of Southern Europe and the Orient, whence it was no doubt introduced into this country about two hundred and sixty years ago. In the autumn the foliage changes to quite a brilliant colour.

ROSE GUSTAVE REGIS AS A LARGE BUSH THIS VARIETY HAS LONG, POINTED, NANKEEN YELLOW BUDS AND IS IDEAL FOR BUTTON-HOLES.

effect is *Silene Schafta*, a little alpine plant that might be grown in almost any garden where such flowers are prized, yet is so often absent. Trailing over rocks or growing in crevices, it is remarkably pretty with its bright pink flowers (which are borne in great numbers) from the end of July and onwards. It is easily raised from seeds, and

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

White Rose Ointment Pot.—I now have pleasure in sending a photograph of the ointment pot referred to on page 374 of last week's issue. It is placed on the trivet or "treft," resting on the logs placed on the "dogs" or "brand irons" as in actual use in olden times, and still occasionally found in remote farmhouses.—ANNE AMATEUR.

Mowing Lawns Without a Grass-box.—Re "Note of the Week" for July 11. This is an operation that should be done with discretion. On lawns that are chiefly grass there is much to be said in favour of it, but how often we see lawns that are nearly all weeds, chiefly the common Daisy. To mow such lawns without a box would be a great mistake, for although the Daisies may be in flower at the time of cutting, many of them have sufficient nutriment left in them to ripen seeds as they lie on the ground, and would thereby make a weedy lawn much worse.—F. G. P.

Dianthus Atkinsonii.—In your issue of July 11, page 353, Mr. S. Arnott, in his notes on *Dianthus*, speaks of *D. Atkinsonii* as a double rose pink. Surely what is generally known as *D. Atkinsonii* has single flowers of a vivid crimson-scarlet, one of the most gorgeous of coloured flowers. It is quite one of the best, and so free that it will often flower itself to death. It is a good plan to prevent one or two plants from flowering, although, if cut down as soon as the blooms are over, enough good growths are generally produced.—F. G. PRESTON, *Botanic Garden, Cambridge*.

Erigeron Edina.—In your report of the Holland House Show you refer in appreciative terms to *Erigeron Edina* as exhibited by Messrs. Bunyard of Maidstone. I am sending you an illustration of a plant to show you what this *Erigeron* is capable of in the way of display. There are probably only two forms of white-flowered *Erigeron* grown in gardens, namely, *E. Coulteri*, a quick-spreading but sparsely flowered species, and *E. neo-mexicana*, a plant of little garden merit. The newer *E. Edina* is a trim-growing dwarf form, flowering over a long period with extraordinary freedom. It originated five years ago at Hopetoun Gardens, and was first offered to the public by Messrs. Cunningham and Fraser, Comely Bank Nurseries, Edinburgh.—T. HAY, *Greenwich Park*. [The photograph sent represented a very good plant, but, unfortunately, was not suitable for reproduction.—ED.]

An Effective Flower-Bed.—Among the flower-beds in Finsbury Park—which just now are in fine condition—are some filled with a combination of dwarf *Heliotropes* and scarlet *Salvias*, with standard *Heliotropes* at intervals at the sides and along the centre. The vivid scarlet of the free-flowering *Salvias* contrasts admirably with the colour of the *Heliotropes*, and the delightful fragrance of the latter completes the charm of what, to my mind, is the most effective of the

whole planting scheme this season, albeit there are excellent beds of *Fuchsias* and also of *Begonias* and scarlet Zonal *Pelargoniums*, with such things as standard silver-leaved *Veronicas*, grey-leaved *Eucalyptus*, pink and rose *Clarkias* and *Grevilleas* to stand above the dwarfer subjects. It will be worth while keeping a note of the idea of using *Salvias* and *Heliotropes* in combination for another season, for a bed in the centre of a grass plot thus planted will produce a fine effect for a long period, and is a break-away from the orthodox Zonal *Pelargoniums* and *Calceolarias*.—HEATHER BELL.

Two Beautiful Violets.—I have never met anyone yet who did not like Violets. There are not many persons conversant with these modest but delightful flowers who do not know the varieties *Princess of Wales*, single, and *Marie Louise*, double. There are, however, two more sorts that should be added to every collection, namely, *Colcroonan*, double, resembling *Princess of Wales* in colour; and *Mrs. J. J. Kettle*, double, light mauve, with a distinct light centre. Both kinds of blooms

AN ANCIENT POT USED FOR MAKING ROSE OINTMENT.

are freely borne on strong stems, those of *Colcroonan* being very long.—AVON.

Lightness in Table Decorations.—Under this heading your correspondent H. A. Elliott raises, in issue No. 2226 of *THE GARDEN*, page 363, an interesting point worthy of consideration. In reference to the "Hints to Exhibitors" mentioned as being printed in the schedule of a well-known Yorkshire horticultural society, I would, at the outset, like to ask whether it is known that that particular society specially favours *Roses* at its shows? Because, if so, that fact would probably account for the bias in the direction shown in the "Hints." The reason for this question is because I happen to have been a member of a large Southern society in which this favouritism has been a conspicuous feature for some years, culminating during the current season in "*Roses only*" being stipulated as admissible in the class under notice. Otherwise, with the knowledge at our disposal, it is difficult to understand how a horticultural committee—the members of which are usually chosen for

the amount of experience possessed in exhibition matters generally—could allow the suggestions quoted to be printed in their schedule, the spirit of which, I venture to think, would be calculated, to say the least, to be misleading, especially to beginners. The majority of your readers will, I feel sure, agree with your correspondent that the value of a decorated table lies in the grace and charm created by its light effect as a whole, so that those around the board may "see through" without difficulty. In regard to the question raised as to the suitability of *Sweet Peas* and *Gypsophila elegans*, perhaps I may be permitted to mention the fact that I have myself, with good *Sweet Pea* blooms, *Gypsophila*—using, however, the double form of *paniculata*, which gives better effect—and other light foliage, been placed in front of competitors employing flowers of a less light character and probably costing considerably more. Not only the blooms, but the stems also of *Sweet Peas* possess the essential quality of lightness. A desirable *Sweet Pea* in

this connection is *Mrs. Townsend*, the colour of which—white and violet—is equally good on the reverse side of the flower. Respecting the use of *Sweet Peas* for table decoration, there is one reservation I would make, which is that unless really first-class blooms are available, it is better to use a subject such as *Carnation May Day* or *Enchantress*, still, however, using the lightest of foliage, together with the *Gypsophila* particularised.—B. W. LEWIS.

An Unusual Rose Stock.—Thinking it may prove of interest to readers of *THE GARDEN*, and especially to *Rose* enthusiasts, I send a brief account of my discovery of an unusual stock having been used for grafting a *Rose* upon. I judge the stock to be a variety of *Cotoneaster*, but enclose a slip so that you may verify the same by a brief footnote. The shrub is now 3 feet or so in height, rather more across, and of a spreading habit. It is about four or five years ago since it first made its appearance above ground

directly in front of a *William Allen Richardson Rose*, say, 15 inches from the chief stem. When first seen we had no idea of what it might be, and as there was no other plant just near, it was allowed to grow. Imagine my surprise when working around the *Rose* and shrub to find the latter growing off a large root which I traced back to the original rootstock of the *Rose William Allen Richardson*. Presumably such an experiment was the work of some nursery employé, and it has certainly answered quite well, for I understand the said *Rose* has been where it now is eleven or twelve years. Of course, the first growths of the *Cotoneaster* were made at the expense of the *Rose*, the vigour of which was much impaired owing to our not being aware of the connection between the two. The flowers of the shrub are quite insignificant, and are just over, but the crimson berries which follow are rather attractive in the autumn and early winter. Has such a case been recorded before?—C. TURNER, *Ken View Garden, Highgate*. [The *Cotoneaster* sent was *C. Simonsii*.—ED.]

New White Climbing Roses.—If Mr. H. E. Molyneux will grow Mrs. M. H. Walsh (Walsh, 1913), he will not be compelled to say "We still want a good white." The new-comer is absolutely white, with rosette-like blooms, freely produced. Its dark, shining foliage, like the bulk of the wichuraianas, makes a good contrast to the pure white flowers. In growth it is all that can be desired, and especially free flowering. Again, if Mr. Molyneux will grow Mrs. Littleton Dewhurst, which is another sport from Dorothy Perkins and pure in colour, much superior to White Dorothy, which is especially inclined to sportiveness this season, he will even then not have to make this complaint.—E. M.

A Good Yellow Gladiolus.—In your issue of April 25 (page 204) a correspondent deals with the newer kinds of yellow Gladioli, but fails to mention Schwaben, a variety raised by Pfister of Stuttgart, and which in Australia surpasses Glory of Noordwijk, which is recommended in the article referred to. Schwaben has been exhibited here with twelve flowers in perfect order at once. The flowers are large and of a fine yellow, and the growth vigorous to a quite unusual degree. This variety was awarded a championship at Moe here on April 17 last. Glory of Noordwijk also has been shown, but has attracted attention only by means of its high price. Golden Empress, a variety raised in Tasmania, is considered by some growers to be equal to Glory of Noordwijk, but Schwaben is always considered superior, though its colouring could be purer. Niagara varies terribly in its coloration, coming almost pink in some soils. Its facing leaves much to be desired also, but it throws a very fair spike.—GILBERT ERREY, Victoria, Australia.

The Most Fragrant Rose.—I spent much time round the new class for fragrance at the Holland House Show, and am not at all surprised to read the remarks of "Old Rose" as to the strength and kind of fragrance contained in the winning blooms of Queen of Fragrance, the variety favoured by the judges and the winner of the "Clay" Cup. To me many of the remarks made by passers-by savoured of the unjust, because they appeared to be quite ignorant of the conditions required and judged the Roses staged by appearance, often ignoring entirely the fragrance altogether. One "expert" put his nose within an inch or so of the flowers and compared the fragrance to some Apples. I rejoined, "More like sour Grapes to you." I know dozens of people condemned the award entirely in ignorance, and I shall not be surprised if we have to read remarks in the Press made by such. While agreeing that Mrs. G. Norwood is a delightful Rose in many ways, and pleasingly sweet too, it must be admitted that the blooms in question were not equal to those selected, as they suffered somewhat from age. I do not mean they were not fresh, but not equal in any way to what this variety was shown much earlier in the season. I think it must be admitted that even the fragrance of a Rose wanes as the blooms become smaller in their season. I tested all the blooms staged most carefully many times after the judges had pronounced their award, and I am firmly convinced that they spared no pains to arrive at a correct decision. I watched them closely all the time they were engaged. Of course, I shall be told this is only a matter of opinion. That may be so, but I want readers to understand that the award was not made in a perfunctory manner by the lady and gentleman appointed.

I am thoroughly convinced no injustice was done to other exhibitors.—EDWIN MOLYNEUX.

Naming of Daffodils.—I have always rather prided myself on taking some pains and care in giving appropriate names to my Daffodil seedlings, so that the criticisms of your Colonial correspondent "A. E. G.," page 362, issue July 18, touch me in a very tender spot. He finds some fault with the naming of Swashbuckler, a flower which, I gather, he has never seen. I am sure that were he to see it, he would at once grasp the appropriateness of the name. Its section is, I should say, on the border line between a Giant Leedsii and a Giant incomparabilis; but it is a great, bold, aggressive-looking flower, with enormous substance both in flower and stem, so much so that when I exhibited it in London a gentleman to whom I was showing it asked me as a favour not to hit him with it! I have no interest in it now, as the stock has passed into the hands of my friends Messrs. Cartwright and Goodwin; but I remember that Mr. Goodwin, when making the purchase, remarked on the particular appropriateness of the name, and I cannot help wishing that "A. E. G." had also had a view of it; in which case I am sure that he would not have included it in his list of undesirable or inappropriate names.—F. HERBERT CHAPMAN.

The Leaf-cutting Bee among Pelargoniums.—Looking over some scarlet Zonals recently, I was surprised to find on many of the flower-trusses that small portions of the petals had been removed by clean, regular, crescent-shaped cuts. I guessed this must be the work of the leaf-cutting bee, although I had never before known this clever and industrious—though destructive—insect to choose the flowers of Pelargoniums for its labours, the usual thing being for it to attack the foliage of Rose bushes. However, I bade my little son keep watch upon the plants, and, sure enough, before long the bee appeared, alighted on a petal, cut out a piece and flew off with it. Having learned that this was the case, I took up the observation myself, and found that, at regular intervals of five minutes, the bee returned to my plants. This showed me that its nest must be a considerable distance off; but by the aid of binoculars I was enabled to watch the bee to ascertain the direction of its flight. Within three days I had traced its home and destroyed it; but not before some hundreds of pieces had been deftly removed from the flowers of my Zonals. Strange to say, although I had Paul Crampel, Jacoby and the Ivy-leaved Mme. Crousse growing side by side with Vesuvius and Raspail, only the last two varieties were attacked, from which I gather that whatever colour is first chosen is adhered to during the whole operation of nest-building. If any readers notice a number of crescent-shaped cuts on their flowers or on their Rose leaves, it will be as well to watch for the leaf-cutting bee, for if unchecked this busy little insect will work extraordinary mischief among the plants.—HEATHER BELL.

FORTHCOMING EVENTS.

August 3.—Flower Show at Carshalton.

August 4.—Flower Show at Abbey Park, Leicester (two days). Scottish Horticultural Association's Meeting.

August 7.—Perthshire Sweet Pea and Rose Show (two days). Dundee Horticultural Association's Meeting.

August 8.—Stirling Horticultural Association's Outing to Callender Park, Falkirk.

THE LILY SEASON IN SCOTLAND.

ORIENTAL and American Lilies in South-Western Scotland have been materially stimulated in their growth and flowering potentialities by the advent of the recent rains. Previously it appeared as if they were making but little progress in the direction of floral evolution. Perhaps the one outstanding exception was the fair Madonna Lily, *Lilium candidum*, which seems less susceptible than many other Lilies of less attractiveness to atmospheric influences. This is still one of the most beautiful of all Lilies, for its flowers are invariably richly ornamental and refined in their fragrance.

L. longiflorum is also for the most part comparatively easy of culture when it is assigned a sunny, sheltered situation and a moderately fertile soil; but only too often it reduces to a minimum its splendid possibilities by the creation of a large number of impotent miniature bulbs. On the other hand, the great Himalayan Lily, *L. giganteum*, which grows grandly at Monreith and Lochinch Castle, though it usually generates several offsets of a considerable size, seldom suffers so perceptibly from this special cause. But then it must be remembered that its offspring sometimes take from four to five years to reach their full dimensions, while those of *L. longiflorum* develop very rapidly. This is especially characteristic of the fine variety entitled *L. Harrissii* when cultivated in a warm conservatory.

In my own garden the first Oriental Lily to flower adequately this season was *L. Hansonii*, the luminous Yellow Martagon, which invariably produces an artistic effect. This variety was quickly followed by *L. szovitzianum*, which this year approximated to a height of 8 feet. Its citron-coloured, pendent flowers are exceedingly graceful. One of the loveliest contemporaries of the Persian Lily in this sequestered region of Scotland is *L. washingtonianum*, a native of California, which, with its charming aspect and delicately Woodbine-like aroma, may be described, without exaggeration, as a veritable gem. Next in order of flowering here come the Siberian *davuricum* (varieties *erectum* and *incomparabile*) and the even more richly coloured Californian Panther Lily, *L. pardalinum*, of which one of the finest and most reliable varieties is *Burbankii*.

L. Henryi, a distinctive Lily from Western China, with a uniquely pendulous characteristic, is at present developing with a gratifying vigorousness; so also are *L. auratum platyphyllum* and *L. virginale*; while the noblest forms of *L. speciosum*, and especially *L. s. Kratzeri* and *L. s. magnificum*, promise to be splendidly impressive this year. DAVID R. WILLIAMSON.

Manse of Kirkmaiden, Wigtownshire, Scotland.

TWO LITTLE KNOWN ANNUALS.

THERE are a number of beautiful annuals that are ideal subjects for the rock garden, among which may be mentioned *Downingia pulchella* and *Eucharidium Brewerii*, the former with large Lobelia-like flowers of rich blue with yellowish eye, and the latter with beautiful pink flowers, which, from an outward appearance, one might compare with the beautiful *Shortia uniflora*, although it is in no way related. Both are natives of California, and are among the gayest of annuals at the present time.

HARDY AMERICAN PRIMULAS.

PROFESSOR BAYLEY BALFOUR classes the nineteen named American Primulas into three sections—*Farinosa*, *Cuneifolia*, and *Nivalis*, though he does not consider this grouping final. It will thus be observed that this area, so rich in other hardy plants, gives us a small number of Primulas. Some of them are of special interest, and the greater number are worthy of more extended cultivation. Of those I mention, all are hardy with the exception of *P. Rusbyi*, which is so nearly hardy with me that I think it desirable to class it with the other hardy American species I have cultivated.

***Primula americana* (Rydberg).**—*P. americana* of Rydberg is admittedly a microform of the widespread *P. farinosa*, and it is classed by some botanists as *P. farinosa* variety *genuina*. It has the leaves farinose beneath, obovate-oblong, obtuse and crenulate or denticulate. It is a native of the Rocky Mountains, and occurs in Alberta, Colorado and Montana. It can be cultivated under the same conditions as other forms of *P. farinosa*, and is an attractive little Primula.

***P. davurica* (Spreng.).**—Pax does not admit this to specific rank, and makes it a sub-species of

***P. farinosa*.**—This is mentioned in my account of the Asiatic, but not Chinese or Japanese Primulas, page 180, April 11 issue, and need not be further discussed at present, except to state that it has been found in Saskatchewan.

***P. eximia* (Greene).**—This member of the *Nivalis* section is spoken of among the Japanese species, page 280, May 30 issue, and reference may be made to that article for further information. It will suffice here to say that it is found in the Aleutian and Pribilof Islands.

***P. groenlandica* (Warming).**—This is another of the microforms of *P. farinosa* which are denied specific rank by Pax. It is a native of Greenland and Labrador, and is *P. stricta* of Lange. The leaves are large for the size of the plant, and are more or less farinose beneath, deeply denticulated or nearly entire, the base narrowing into a short petiole. The scape is stout, and rises above the leaves. The flowers are violet. Cultivation: Same as *P. farinosa*.

***P. magellanica* (Lehmann).**—In this we have another of the *Farinosa* section which is classed by Pax as a variety. For garden purposes it may be called a form of the Bird's-eye Primroses. It is a robust form, with rhomboid-elliptic, crenate-denticulate leaves, the sturdy scape rising above these. The flesh-coloured or white flowers are almost capitate or on short pedicels. The habitat of this Primula is one of the most curious in phytogeography. How this Northern species has contrived to jump over the whole American Continent, to pass the Equator, and to establish itself in the extreme South, is a mystery as yet unexplained by science. It is found in Fuegia and Chile, and is plentiful in the Falkland Islands, where, on a few of the islands where there are no sheep, the hillsides are covered with its white

or lavender-coloured flowers, and these grow to 1½ feet to 2 feet high. In former years it reached that height in all the islands, but the species has dwindled in size since the introduction of the sheep. It is a good garden plant.

***P. mistassinica* (Michx.).**—Another form of *P. farinosa*, *P. mistassinica*, which is *P. pusilla* (Goldie), *P. tenuis* (Small) and *P. Macalliana* (Wiegand), is a considerably smaller plant, and only grows from 1 inch to 6 inches high. It has spatulate or obovate leaves, which are generally green on both sides, but are occasionally sparsely farinose beneath, and denticulated or repand, obtuse at the apex, and narrowed or cuneate at the base. The flowers are from two to six in the umbel, and are pink or pale purple, with or without a yellow eye. The corolla lobes are obcordate. It is a native of wet banks, and extends generally from Newfoundland to the Rocky Mountains. It is also found in Northern Europe.

***P. Parryi* (A. Gray).**—This native of the sides of the alpine brooks of North America comes from

out by the general experience. It is a very distinct species of the *Cuneifolia* section, and came from the Rockies of Arizona and New Mexico in 1885. The leaves are sometimes as much as 4 inches in length and rather more than half that in width. The flower-scape rises a little above the leaves and bears an umbel of from two to ten peculiarly scented flowers of a crimson-purple colour, nodding to one side, with a deep irregular ring round the yellow throat of the corolla. The calyx is prettily striped with white meal. I cannot grow it in the open, but it succeeds moderately well in a cold house with the pots plunged in and covered over with ashes during the winter season. It blooms with me, although late, but does not seed.

***P. integrifolia* (Gumer ex Oeder).**—It will, perhaps, be better to speak of this plant as a form of *P. sibirica*, of which it is a microform. As I shall refer to *P. sibirica* in connection with the Himalayan species, it is needless to deal with it in detail now. It is, of course, quite distinct from the European *P. integrifolia*, L.

***P. suffrutescens* (A. Gray).**—This sub-shrubby species, introduced in 1884 from Sierra Nevada, proves fairly hardy with me in a sheltered, well-drained spot in the rockery, but I find it does better when grown as a pot plant in a cold house. It has much the appearance of a dwarf shrub with its branches lying along the ground. The pretty pink flowers are borne well above the leaves on erect stems. Partly owing to the fact of the branches resting on the ground, they are apt to rot off during the winter months. This species, like others, is best raised from seed, but can also be increased by layering and from cuttings. Cultivation: Light, well-drained soil, with a fair amount of sun.

***P. Warei* (Stein) = *P. americana* (Rydberg).** JOHN MACWATT.
Morelands, Duns.

PRIMULA RUSBYI, A LITTLE-KNOWN SPECIES WITH CRIMSON PURPLE FLOWERS.

near the snowline of the Rocky Mountains, from Colorado, through Nevada and Arizona. It was introduced in 1875, and figured in the *Botanical Magazine* of the same year. In that publication it was said to be the handsomest Primula in cultivation with the exception of *P. japonica*. Having grown this Primula in quantity, I cannot share or support this opinion. All the same, it cannot be denied that it is a good plant, although difficult to cultivate in most places. I have no difficulty with it planted deeply in good soil in a Rose bed. It has bright purple flowers, about an inch across, with long scapes bearing frequently a dozen blooms in an umbel. The leaves are sessile or narrowed into a broad petiole, erect, obtuse or sub-acute, and obscurely toothed or entire. It is from 6 inches to 18 inches high. Cultivation: Good rich, well-drained soil in half shade facing west.

***P. Rusbyi* (Greene).**—Unfortunately, I cannot say that *P. Rusbyi* is hardy and easy to grow—at least, it is not so with me, and this is borne

and are excellent flowers for the border, the wild garden, or the open parts of the woodlands, where, when plentiful enough to mass in broad array, they would make a much finer effect than if planted dotted here and there in the woodlands.

They are, however, choice enough and good enough for planting in the flower border. The Gillenias are close allies of the Spiræas, but do not produce their flowers in the large panicles generally borne by these valued plants. The flowers are white or pinkish, but few are quite devoid of the tinge of pink, which lends a little additional brightness to the flower.

As will be understood from the introductory remarks, these Gillenias present few obstacles to the cultivator, but they dislike a poor and dry soil. A moist situation is preferred, and this can be afforded in most gardens. They rather like some shade, so that they are valuable for shady places—no slight recommendation in many gardens. There are two species of Gillenia, the first, *G.*

GILLENIAS AND THEIR CULTIVATION.

THE Gillenias are graceful subjects, known to some American botanists as the *Porteranthus*, in lieu of the more acceptable name of Gillenia, to which we are most accustomed. They are elegant, Spiræa-like plants of much beauty, although not of a showy nature,

trifoliata, the Indian's Physic or Bowman's Root of its native land, the Northern United States of America. It grows from 2 feet to 4 feet high, and is the finer of the two species. It has narrower stipules than the succeeding one, and is glabrous and not pubescent, as is the latter. The other, *G. stipulacea*, the American *Ipecacuanha*, is much the same in general appearance, but is inferior as a garden plant because of the fact that it has fewer and smaller flowers. The *Gillénias* are increased by division in spring or autumn, and can also be raised from seeds.

S. ARNOTT.

HYACINTHS, NARCISSI, AND TULIPS FOR FORCING.

THE time has again come round when the preparation of forcing bulbs must be concluded; for, be it said, preparatory proceedings have been going on for a long time. Narcissi lifted some weeks since for pot culture were planted two and three years ago, and only the best of these have been selected, the inferior ones being replanted for outdoor flowering and for the production of forcing material in the future. Commonly called Dutch bulbs, as is well known, undergo similar preparatory culture, extending over years, the cheaper qualities being immature and, consequently, incapable of producing the best flowers. I have nothing to say against "cheap" bulbs, and there is no good reason why they should not be a marketable commodity, only it should be understood that a Daffodil, for instance, that has been grown from an offset one year, and then may or may not yield one bloom of inferior quality, cannot compete with a three year old bulb giving its two or three superior blooms, and for which an enhanced price is charged, though it is fair to say only slightly enhanced in comparison to the superior results.

In Tulips the blooms are larger, and in general better coloured in high-class bulbs than in immature ones; and in Hyacinths the spike is quite another thing from the feeble production of the third-rate quality. The same occurs in Lily of the Valley, Crocuses, *Spiræas* and other forcing material, and no cultivation, however proper, will have the slightest effect in improving the flowers beyond the limits prescribed by their previous treatment. In a bulb of mature age, furnished with the embryonic foliage and flowers of the succeeding season, cultivation brings out the highest quality it is possible to attain, and it is with these that failure, less or more obvious, occurs when the cultivation is indifferent.

The principle the bulb-grower has to go upon, therefore, is to endeavour by a treatment proper to the special plant to induce it to perfect the future flowers and foliage concealed within the bulb to the greatest possible limit. Everything that the future can bring forth is already there,

and cultivation is concerned solely in exhibiting its proportions in due season.

The Best-Sized Pots.—It is a very good old rule that the material for forcing early should be allotted to smaller pots than that not to be subjected to that treatment, which it will be seen resolves itself into a question of time to make the needed number of roots, and also to allow for shortening the time the requirements of the plant naturally demands. That this is by no means an unimportant part in early forcing is proved by Continental material, which comes to maturity annually in advance of that produced at home, forces more easily than the latter, and also from the fact that forced bulbs planted in the open retain for a time the earliness thus forced upon them. This rule applies more to Narcissi and Hyacinths than to Tulips, but in all it is worth keeping in mind. I use for Hyacinths 4-inch, and for Narcissi 5-inch, pots. For early forcing, Tulips do well enough in 5-inch and 6-inch ones.

compost, free for the roots to penetrate, does away to a large extent with the need of a cumbrous drainage system. Thus for Narcissi, which I grow in 5-inch to 9-inch pots, one piece of potsherd is as a rule all that is employed, with a layer of rough material laid upon it. Tulips need no more, but Hyacinths are less complacent, and for 6-inch pots small potsherds are necessary as well as large ones. It is clear that space unappropriated—shall I say misappropriated?—by drainage provides an additional space for soil, hence a larger root-run, and this may be further increased by keeping the bulb well up. Bulbs of Narcissi need very little of their bulk buried, Tulips rather more, and Hyacinths should not be much exposed.

As already hinted, Narcissi and Tulips should be potted with the bulbs almost touching, and it therefore depends on the dimensions of the bulbs individually how many shall be grown in each pot. The earliest Hyacinths, such as General Pélissier, do well one bulb in a 4-inch

PRIMULA SUFFRUTESCENS, A NATIVE OF SIERRA NEVADA. THE FLOWERS ARE PINK.

For Narcissi and Tulips I pack as many bulbs into a pot—of whatever dimensions—as it will hold. Provided the compost is suitable and plenty of roots as a result are produced, all that is necessary for the grower to see to is that the plants are well fed and never neglected.

The Soil.—It is a well-known fact that these plants can perform all the functions of leaf and flower production on water and on fibre; hence the grower who fails to provide a compost deficient in porosity—one in which leaf-mould, for instance, is largely proportioned, and sand, if required—is to that extent courting disaster. So also the compost should not be compressed to anything like the extent of ordinary greenhouse plants, and it is noteworthy that the very unsuspecting-like practice of pressing a Hyacinth or Tulip into the soil may result in its roots refusing to enter the soil at all, and to throw the bulb upwards, a derelict for the nonce. A nicely imagined

pot, and for 6-inch pots three in a pot is the number I use. Darwin Tulips require slightly more space than the early singles and doubles, and very glorious masses of the former are provided when 8-inch and 9-inch pots are used. In these large pots the bulbs may be arranged in two stages, one lower than the other, and by staking out the outermost plants large specimens suitable and, indeed, indispensable for decoration are secured. Space is exhausted, but I would like to add: Do not attempt to grow many varieties. To have very early flowers, rather confine yourself to one Tulip, Proserpine; one Hyacinth, General Pélissier; and one Daffodil, Golden Spur. Pot all the Narcissi at the earliest moment, the others when they come to hand, with relays in September and October; and in forcing proceed slowly till the flower spike or stem shows that it is pushing freely, darkness up to an advanced stage having a very favourable effect.

R. P. BROTHERSTON.

NOTES ON JAPANESE IRISES.

IN spite of continuous drought in our East Coast district, 1914 has otherwise been a good year for Japanese Irises, and a few notes concerning them may be welcome to many readers. The standard Japanese forms, including the lovely Deep Blue Waters, have been very fine, and several of these are worthy of mention. Among the more notable of the Japanese forms I will name Zama-no-mori, a beautiful, large, three-petalled form, pure white save for the yellow blotches and just

the lawn or grassland, so that it would be an easy matter to flood the Iris plants during dry weather. For manuring, nothing equals cow-manure.

Propagation is chiefly confined to division, and here let me advise the reader as to the time of operation. All division of the Japanese Irises is best effected directly after flowering. The clumps should be carefully lifted, and each strong growth severed separately with the roots attached. These should be potted up in enriched soil of which the body is good loam, using 4½-inch pots. After potting, place the plants on a good ash-bed in the open, and keep them watered as necessary with a rose-can, damping the foliage

JAPANESE IRISES EFFECTIVELY GROUPED BY THE WATERSIDE AT WISLEY.

a suggested suffusion of light blue. Kumo-no-obi, the lovely Band of Cloud of the Japanese, is a lavender purple, with the yellow blotches halved in white, a pretty three-petalled form. Very noteworthy is Shirataki, the White Waterfall, with its fine white petals of marvellous beauty. With its six massive petals Shirataki is one of the grandest Irises in existence. Kyodaisan is purple with blue and striking orange blotches, and is of high merit. This, again, is six-petalled. Choseiden is ruby crimson, a lovely big flower with a halo of white surrounding the yellow blotches. Kasugano, a red lilac variety, is a glorious flower, and worthy of attention. Then there are Oyodo, a large violet blue; Momiji-no-taki, crimson purple, suffused and feathered with white; Warai-hotei, a large lavender blue; Osho-kun, a brilliant Tyrian blue; Yedo-jiman, deep blue and purple; and several others equally noteworthy.

For the interest of readers I add a few cultural notes. The Irises are worthy of the utmost attention in the matter of sites for planting. The ideal position is one where they can grow with their heads in the sun and their toes in the water. A deep, loamy soil, plenty of moisture, and an open position with full exposure will be ideal. If one possesses a garden pool or a winding stream, it is an easy matter to make an Iris swamp or Iris garden. If no waterway is possible, the next best plan would be to make some sunken beds in

as well as the soil. In a short time the pots will be full of new roots. Then the new situations or beds can be prepared, working soot, cow-manure and perhaps a little bone-meal into the soil. Deep cultivation is a great asset toward ultimate success, and if the above system is followed, the young plants are established before the winter.

Now for just a few words in reference to our own hybrid seedlings of 1914. This year we have flowered many fine seedlings, of which the best have been marked for propagation. A few of the best are: Matsushima, a large six-petalled flower of a soft sky shade, overlaid with a suffusion of blue, and lines of blue which deepen to purple at the edges. The usual yellow blotches are very conspicuous, and the plant strong in growth. Kameido, a lovely ruby red of immense size, with a big halo of white around the golden blotches, is very striking.

Lady Marjorie is another large six-petalled form with a ground colour of white. The petals are delicately lined and suffused with blue and purple, and the usual characteristic yellow blotches are most effective. The Dove, a pure white, which will be quite worthy to rank with the standard whites Shirataki and Zama-no-mori, is six-petalled, but differs from most white Kämpferis by reason of its carrying three petals as standards. These three are pure white, but the fall petals have the yellow blotch.

Clacton-on-Sea.

P. S. HAYWARD.

COLOURED PLATE.

PLATE 1499.

DAFFODILS IN GRASS.

IT has never been my good fortune to see the Daffodils in the grass in bloom at Kew, but if anything would make me undertake a journey there next spring to have a look at them, it would be the coloured plate in this week's issue. They are arranged just as I would plant them myself, not in one huge homogeneous mass, whose only charm would be its size and solid magnificence, but in patches of irregular size and varying contour, some of which would contain only two or three bulbs, while the largest ones might be made up of two or three hundred. These groups I would place "anyhow" in the space to be allotted to them, taking care that there was always a sufficiency of unplanted grass between them. Kew fulfils my ideal in this respect also.

Thirdly, it will be noticed that all the flowers in the foreground of the picture are all of one kind, probably either Empress or Horsfieldii, and that it is not until the trunks of the large trees are almost reached that we have a change, when the white effect gives place to an expanse of yellow, it might be of Emperor or Sir Watkin, or even princeps. This is on quite the right lines. In striving to get the best effects in a garden, massing is always a very important factor, but never more so than in planting Daffodils in grass or in a woodland. Keeping the different kinds by themselves does more than anything to lend a charm to the scene; while, on the other hand, planting in dabs only gives us a sense of muddle.

These, then, are the three main principles which, I think, should guide all Daffodil planting in grass: (1) Plant in irregular masses of one variety; (2) leave grass spaces between the clumps; (3) keep the masses of the same variety more or less together. I do not think I am divulging any editorial secrets when I say that Kew and myself are supported by no less eminent an authority than Sir Frederick Moore of Dublin, who will have an article on "Daffodils in Grass" in the 1914 Royal Horticultural Society's "Daffodil Year Book," in which he records his practice and experience in the Botanic Gardens at Glasnevin, where, some five years ago, it was my privilege to see them in their full glory. "There can be no comparison as to the more pleasing effect of a bold expanse of one variety and of a mixture."

Proceeding from the general to the practical, I would say that nearly any variety may be used, and that the only consideration that need very much trouble the planter is the effect that he wants to produce—I mean, for example, if a succession of bloom is required, or if a gradation in shading is thought desirable. Catalogues must then be consulted where times of flowering and colour descriptions are given. Apart from all particular requirements, the following are among those I have found satisfactory: Lobularis, John Bull, Stella, Horsfieldii, Emperor, Citron, princeps, triandrus albus, Queen of Spain, Poeticus recurvus, Sir Watkin, Barrii conspicuus and Mrs. Langtry.

A SPRING SCENE AT NEW.

The best time to plant is in October, or even early November if the autumn has been a dry one. In any case a sufficiency of rain should have fallen to thoroughly moisten the ground. The work is then much more expeditious, and the bulbs commence to root "right away." I always use a Barr's Bulb Planter, and from my own experience it is what I would advise anyone to work with who is going in for grass planting on an extensive scale. Three men (or women, for women can do the work very well) are best for the job—one to make the holes, one to place a little good soil in the bottoms, and a third to put the bulb in and replace the round bit of turf.

In the clumps plenty of room should be left between the plants to allow for their natural increase. Six or even eight or nine inches is none too much to allow in the case of the larger and more robust varieties.

Lastly, even if it is like taking coals to Newcastle, I must insist upon the practice of leaving the foliage uncut until about the middle of June, when the foliage has gone yellow. One year's premature cutting off will only weaken, but a second will probably kill the bulbs, as I know the powers that be in a famous garden not long since found out to their cost.

JOSEPH JACOB.

THE GENUS COBÆA

AS long ago as 1880 I contributed an article on the genus *Cobæa* to THE GARDEN (Vol. XVII., page 352), embodying the species then known with their distribution, and other particulars and descriptions of two new species. Altogether eight species are there dealt with, including four that were, or had been, in cultivation. Two years later I had no additions to make to the genus in the Botany of Godman and Salvin's "Biologia Centrali-Americana." But a synopsis of the species by Mr. A. Brand in 1907 brings the number up to eleven, and in a revision by Mr. P. C. Standley in an American publication, received a short time ago, the total is increased to eighteen.

It may be useful to repeat some of the information I gave thirty-four years ago before giving the new. *Cobæa* belongs to the same family as *Phlox* and *Polemonium*, and it is singular in the family in habit, climbing by means of tendrils. The species are all American, ranging from North Mexico, through Central America, to Chili, Venezuela and North Brazil; but none has yet been discovered in the West Indies. They grow naturally in humid, subtropical forests, and some of them, like the familiar *C. scandens*, reach the tops of tall trees. *Cobæa* was founded on *C. scandens*, which has, it will be remembered, a campanulate corolla not unlike that of the Canterbury Bell. In 1856 Oersted described an allied plant under the name of *Rosenbergia gracilis*, though it had all the essential characters of a *Cobæa*, except the corolla. This is smaller and deeply divided into slender lobes, and of very different appearance.

Later explorations led to the discovery of species intermediate in the shape of the corolla; hence the species are all now placed under *Cobæa*. On the ground of invalidation, Mr. H. D. House transferred all the species of *Cobæa* to *Rosenbergia* in 1908, but this change has not been sustained. The species of *Cobæa* are:

C. penduliflora (Standley; Karsten).—"Flora Columbia," Plate 14, under the name of *Rosenbergia penduliflora*. Native of Venezuela, but no particulars of locality are on record. This is not the plant cultivated under the same name. See next species.

C. hookeriana (Standley).—The same as *C. penduliflora* (Hooker), *Botanical Magazine*, Plate 5757. Native of Venezuela. Raised at Kew from seeds received from Mr. A. Ernst, and flowered in the Palm House in December, 1868.

C. panamensis (Standley).—Native of the mountains of Chiriqui, Panama, at elevations of 4,000 feet to 5,650 feet. This differs from *C. hookeriana* in having a deep purple corolla with very narrow lobes and narrow calyx lobes.

C. aschersoniana (Brand).—Native of Costa Rica at elevations of 6,000 feet to 7,000 feet.

C. triflora (Donnell Smith).—Native of Guatemala at about 4,500 feet.

C. campanulata (Hemsley).—Native of Atacama, Chili.

C. minor (Martens and Galeotti).—Native of Mexico and Costa Rica, ascending to 10,000 feet.

C. Trianaei (Hemsley).—Native of Colombia; imperfectly known.

C. pachysepala (Standley).—Native of Guatemala at 9,000 feet to 10,000 feet.

C. tomentulosa (Standley).—Native of Guatemala at about 8,000 feet.

C. baurita (Standley).—Native of South Mexico at 4,000 feet to 5,500 feet.

C. Pringlei (Standley).—Native of North Mexico, in the Sierra Madre, near Monterey, Nuevo Leon. This locality is far north of that of any other species. The flowers are very similar in shape to those of *Campanula carpatica*.

C. stipularis (Benth).—*Botanical Register*, XXVII., Plate 25, 1841. Native of Mexico; introduced by Hartweg.

C. scandens (Cavanilles).—*Botanical Magazine*, Plate 851. Native of Mexico. I find no records

ANOTHER VIEW OF THE JAPANESE IRISES IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT WISLEY.

Corolla intermediate between typical *Cobæa* and typical *Rosenbergia*.

C. gracilis (Hemsley).—The type of Oersted's genus *Rosenbergia*. Native of Costa Rica and Panama. Flowers small; colour not given.

C. viorna (Standley).—Native of Guatemala up to an altitude of 3,500 feet. Flowers greenish yellow, about one and a-half inches long.

C. villosa (Standley).—Native of San Salvador.

C. lutea (Don) = *C. macrostemma* (Pavon) — *Botanical Magazine*, Plate 3780. Native of Guatemala and Costa Rica. Raised at Kew from seeds sent from Guatemala

of altitude beyond "near the city of Mexico," which is situated above 7,000 feet. The date of the introduction of this species is usually given as 1792, the year the figure was published in the *Botanical Magazine*; but in the text it is stated that the drawing was prepared from a plant that flowered in Woodford's nursery in 1784.

For showiness of flowers none of the foregoing new species enumerated excels *C. hookeriana* (*C. penduliflora*) and *C. scandens*, but several of them surpass the cultivated species in grace and elegance.

W. BOTTING HEMSLEY, LL.D.
Strawberry Hill.

AUGUST NOTES ON VEGETABLES.

Peas.—Although it is now late to make sowings, should the weather be favourable during September and October the resultant crop would be found extremely useful. Varieties best suited for sowing now are The Gladstone, Ne Plus Ultra, Goldfinder, Late Queen and Latest of All. Make a good preparation before sowing the seed, dig deeply, and well soak the drills before sowing if the soil is at all dry. This will hasten germination and encourage the plants to grow quickly. Keep the plants well watered and mulched to guard against mildew attacks. On the first sign of this fungus dust the plants with sulphur, or syringe them with an antidote, such as Seride. Established rows coming into bearing should be freely supplied with liquid manure, or even clear water, to facilitate growth and the swelling of the pods. Mulching with half-decayed manure is a valuable aid

turning in; placing a leaf over the heads keeps them fresh and pure in colour. The growing leaves should be cracked across the midrib in a position sufficiently long to cover the flower, as these leaves last fresh so much longer than a separated leaf, which so soon withers during hot weather.

Potatoes, in spite of the drought, are looking remarkably well where the preparation was of the best—deep digging and liberal manuring in the autumn, and the soil frequently stirred between the rows since planting. No time should be lost in spraying the haulm for the second and last time. Many persons do not think spraying is of any value in preventing disease. I have noted that those who spray regularly have less disease than those who do not spray at all. In any case, spraying does no harm, and it certainly prolongs the life of the haulm, to the advantage of the crop. Strawsonite Bordeaux mixture dissolved in clear cold water at the rate of 20lb. of Strawsonite to 100 gallons of water is sufficient

surface, afterwards watering it in. The plants under glass should have similar attention in the matter of pruning off surplus shoots and shortening back the leaves where they are too plentiful for the fruit to obtain sun to aid ripening. Indoor plants should not be too freely fed with strong stimulants, as they are more liable to attacks of disease than outdoor plants during hot, dry weather. The first signs of disease in the leaves necessitates prompt measures being taken to arrest its progress, cutting off those affected at once and dusting the plant with flowers of sulphur.

Turnips.—Continue to sow Snowball and All the Year Round, first watering the drills to expedite germination of the seed. Directly the plants appear above the soil, dust with wood-ashes and soot. Water frequently to encourage quick growth and to ward off Turnip fly attacks, and keep the soil between the rows well stirred.

Brussels Sprouts well repay any extra attention in watering and mulching during dry weather, as, the taller the plants grow, the greater will be the crop of sprouts later on. The reason so many persons fail to grow this estimable winter vegetable well is because they defer sowing and planting too long, the consequence being the plants have not the opportunity to attain even a reasonable height. If tall-growing sorts like Matchless and Exhibition grow 4 feet high, all the better. Any plants that do not appear vigorous should have assistance in the shape of a pinch of nitrate of soda sprinkled around the plant. This stimulant will quickly give a fillip to growth.

Carrots.—Now is the time to make preparation for an early winter supply of succulent roots of the Horn type. Sow in rows in frames that have been used for Potatoes or Marrows, the soil for those crops being of the right kind for Carrots. Shade until the plants are showing through the soil; then remove the lights daily, encouraging a stocky growth. Replace them as the nights become cooler.

Swanmore.

E. MOLYNEUX.

CLEMATIS GRATA GRANDIDENTATA, A NEW AND ROBUST VARIETY FROM CHINA. IT NEEDS PLENTY OF SPACE FOR ITS VIGOROUS SHOOTS.

to the prevention of mildew, which is caused in a dry season by drought at the roots.

French Beans.—A sowing should be made in cold frames so arranged that the lights can be put on as the nights lengthen and become colder. The crop from this sowing will be found extremely useful in October. Sow thinly to enable the plants to grow sturdily, as under such conditions they will give double the crop of those drawn up by overcrowding. Selected Ne Plus Ultra and Canadian Wonder are excellent varieties. The plants already bearing in frames should be well supplied with water, syringed daily, and have the Beans picked as fast as they are ready.

Cauliflowers should be in abundant supplies of the best quality. Those plants intended for use in September and October should have copious supplies of liquid manure during dry weather, and a mulching around the plants with half-decayed manure, thus encouraging a freedom of growth which gives pure white succulent heads. Attention should be closely paid to plants just

for an acre. An ordinary knapsack sprayer of the pneumatic pattern answers well for a small patch. It is not the quantity of liquid that is required, but it should be evenly distributed over the under side of the leaves equally with the upper surface. As the early varieties ripen they should be lifted and the seed carefully stored when dry in a cool shed, selecting tubers 20z. in weight as a fair sample. The idea that it is necessary to expose them sufficiently long for the skins to become green is not now believed in.

Tomatoes.—Outdoor plants are growing freely, as they revel in hot weather as long as they are sufficiently supplied with moisture at the roots. Restrict the growth to two stems at the most, removing all side shoots as fast as they appear, and keep the leading shoots neatly tied to supports of some kind. Plants carrying full crops of fruit should have a mulching of half-decayed manure and be liberally supplied with liquid manure or a sprinkling of superphosphate of lime on the

A NEW CHINESE CLEMATIS.

CLEMATIS GRATA GRANDIDENTATA is a new variety introduced from China by Mr. E. H. Wilson, who describes it as "a mountain plant abundant in the thickets, margins of woods and copses throughout Central and Western China." The species *C. grata* is a Himalayan climber allied to our native Traveller's Joy, *C. Vitalba*. The subject of this note is readily distinguished from the type by its larger and coarsely toothed leaflets. The leaves are pinnate, comprising five leaflets. The flowers are white, about an inch across, and, as can be readily seen in the illustration, they are terminal and axillary, forming a pleasing and attractive spray. The flowering season is the end of May and the first half of June. In common with some other Clematises, the flowers are followed by attractive silvery seed-vessels. *C. g. grandidentata* is very vigorous in growth, quite as luxuriant as, if not more so than, *C. montana*, which has long been a favourite in gardens. Suitable positions for planting are where it can ramble over and clothe arbours, summer-houses and out-buildings, or climb up and entangle at will trees and tall shrubs. Seeds, cuttings and layering form ready means of propagation.

A. O.

GARDENING FOR BEGINNERS.

HOW TO GROW CYCLAMEN.

THE Cyclamen is a very useful plant for the amateur to grow. It does not require a high temperature; it does not need a large, expensively built house; and, when in bloom, the flowers remain fresh for a long time, and as bud follows bud in development, the flowering season is a long one. One year old plants are

CYCLAMEN SEEDLINGS AT VARIOUS STAGES OF GROWTH. SEE TEXT FOR DETAILS.

valuable for flowering, and corms several years old are also valuable, so that it is not difficult to keep up a good succession when once a stock is raised.

Sowing Seeds.—At the end of July and in August seeds may be sown in shallow pans filled with good loam and leaf-soil in equal proportions. Some coarse sand must be added and, if procurable, a small quantity of old mortar rubble. Drain the pan with clean crocks and place a few half-decayed leaves on them before putting in the compost, which should be gently firmed and made smooth on the surface. Water it through a rosed watering-can, and sow the seeds an inch apart an hour afterwards. Cover them quite half an inch deep with the finer part of the compost, and place the pans in a cold frame or on a stage or shelf in a cool part of the greenhouse. The seeds do not germinate very quickly nor evenly, so that the cultivator must have patience. In the meantime he must keep the soil in the pans in an even state of moisture, and this can be ensured by immersing the pan in a vessel of water and holding it there until the water has come to the surface; then gently lift out the pan. Owing to the irregularity of the germination of the seeds, the most forward seedlings will be ready for transplanting before the later ones, and they should be lifted from the pans carefully so as to avoid disturbing the latter.

Transplanting the Seedlings.—They must be transferred to other pans and be allowed a distance of 2 inches from seedling to seedling. No. 1 shows the seedling breaking through the soil; No. 2, the next stage of development; and

No. 3, the stage of growth when it is advisable to do the first transplanting.

The First Potting.—When the young plants are as far advanced as shown at No. 4, they must be placed in small pots, small 60's—those 3 inches across—being the most suitable size.

The Young Plant is potted, as shown at No. 5, in good compost on a rougher one of similar quality; No. 6, the pot being drained with a few crocks, well placed. At the second repotting the corms will be forming freely, and the dark line in No. 7 shows how deep the corm must be buried. The crown of a Cyclamen corm increases rapidly when in a healthy condition, and if any of the central portion is buried by soil, owing to the cup-like formation, which holds moisture, some of the young growths would perish if constantly surrounded by too moist soil. Moisture resulting from watering is only harmless when the crown is above the soil-level.

The Final Potting.—A seedling Cyclamen may be flowered in a 5-inch or a 6½-inch pot. The latter must be clean, and the compost, though rougher, similar in quality to that used at previous repottings. Old corms need only have one potting. If they are just started, surrounded by sifted leaf-soil, in beds or boxes, the one potting will suffice. Of course, as old corms vary in size, pots must be used accordingly. A corm measuring 3 inches across requires a pot 6½ inches in diameter. As old corms do not possess as many roots as young plants that have been potted for some months, very careful watering is needed. The same care as is given to the seedlings will be correct for the newly potted old corms. No. 8 shows a plant finally potted; and No. 9, young plants in a frame on a bed of ashes prior to taking them to a stage in the greenhouse. If the structure is a very dry one as regards atmospheric moisture, place slates on the stage and ashes on them for the accommodation of the Cyclamen. If the interior of the house is naturally moist, put the pots on the bare stage. There should be medium atmospheric moisture and free ventilation as required; then very fine flowering plants will result.

G. G.

STARVING PLANTS IN SMALL POTS.

THE amateur cultivator is often prevented from repotting certain plants on a given date. Their condition a few weeks afterwards does not impress him very much, because they all look to be in the same state; but if a few have been repotted or planted out, then the difference is marked indeed. I lately saw several hundred Cucumber plants that had been planted in borders a week previously. One, however, had been retained in the pot. Those planted out were 20 inches high and branching out freely. The pot plant from the same batch was about ten inches high and had very short side shoots. Retaining plants in their pots a week or a fortnight longer than they should be means a big loss of valuable time, as well as poorer specimens, because if the plants receive a check, they rarely afterwards recover sufficiently to make satisfactory plants.

In another case some Perpetual-flowering Carnations were left in small pots. Others from

the same batch were duly repotted. Result: The repotted plants at the end of a fortnight were as large again as the unpotted ones. The former will be strong flowering plants this autumn, while the others will not be as good next spring—loss of time and flowers too. Many greenhouses would be much brighter if the plants were more systematically repotted as required. Fewer plants would be needed to fill the stages, and the quality of the plants would be raised.

SHAMROCK.

HOW TO DRY HERBS.

HERBS are of much value if properly treated, but they are rarely well cultivated and cared for in our gardens. In this brief note, however, I do not intend to deal with the culture, but with their treatment during the autumn and winter months. All herbs that are cut and stored must be harvested while the plants are in full flower. It is at this stage that the plants are at their full strength. To retain that strength, careful harvesting is necessary. The tops must be cut off, but not immediately tied in bundles. Adequate drying is essential first, and this is secured by spreading out the herbs on a strip of netting in an airy shed. The air can pass freely through the stems and leaves, and if spread out thinly in this fashion, turning is not necessary. When the stems and leaves are sufficiently dried, tie them loosely in small bundles and suspend them from the roof or any convenient projection in an airy, cool shed. From the time that the tops are harvested till their use they must not be openly exposed to any strong sunshine.

The Herb Plants.—Having secured the harvest of leaf and flower, the cultivator must turn his attention to the plants themselves. In the case of some of the old and weakly clumps, dig out the centres, removing roots, stems and soil bodily; then with a good rich compost fill up the hole made.

G. B.

A CYCLAMEN PLANT IN ITS FLOWERING POT, AND YOUNG PLANTS STOOD ON ASHES IN A COOL FRAME.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Late Vineries in which the Grapes are swelling freely should be ventilated with great care, especially houses in which Lady Downe's Seedling is grown. When this Grape reaches the stoning stage, the ventilators ought to be left open during the night, or many of the best berries are almost sure to become scalded. Ventilate freely during the day, opening the ventilators in front of the structure as early as the weather will permit. Regulate and stop lateral growths before they become hard and overcrowded. This will do much to produce a free circulation of air among the fruit and foliage. Well-drained borders should receive a thorough soaking of liquid manure, but never of sufficient strength to injure the young roots.

Plants Under Glass.

Begonia Gloire de Lorraine.—The earliest batch of these winter-flowering plants should now be ready for their final potting, and the soil for this purpose may be composed of turfy loam and leaf-soil in equal parts, with a good sprinkling of rough silver sand. Pot moderately firmly and shade from strong sun. Hanging baskets can also be made up now, and these will produce a very pleasing effect during the winter. Do not overcrowd the plants, and apply the syringe frequently to keep insect pests in check.

Schizanthuses.—To produce good plants for spring flowering, the seeds should be sown about the middle of August. Sow thinly in pans of fine light soil and place in a cold pit until the young plants are well through the surface, after which the pans should be raised quite near the roof glass in order to keep the plants stocky. Prick off into boxes as soon as large enough, and again into 3-inch pots later in the season. In these they may remain the winter, and the final potting can take place early in spring.

The Flower Garden.

Climbing Roses.—Many of these are in flower now, and the worthless shoots from the base of the flower-trusses should be carefully removed, otherwise the flowers are not seen to advantage. Young shoots from the base of the plants may be tied in, but nothing more than what is required to furnish the trellis next season. When the flowering season is over, as many old stems should be removed as possible, in order to make room for young growth which will produce next season's crop of flowers.

Violets.—These plants have made good growth during the last few weeks. All side shoots should be removed and the Dutch hoe frequently used among them. Syringe freely and dust the plants with soot as the best means of keeping red spider in check.

Violas.—As soon as these have finished flowering they should be cut hard back, in order to produce cuttings for next year's supply of plants. When about two inches long, these young shoots may be carefully removed from the old stools and planted in a cold frame or in some sheltered spot where protection can be afforded during very frosty weather.

Summer Bedding Plants.—Many are at their best now, and will require regulating to keep them within bounds. Pelargoniums may be the first to receive attention, and this should be done with a view to securing some cuttings for next season's display. If only one of the hardest shoots can be spared from each plant, this will be sufficient for a start. When the cuttings have been prepared, they should be inserted in small pots of sandy soil and placed on a bed of ashes in the open until the autumn, when they may be removed to some slightly heated pit and within 18 inches of the roof glass, there to remain for the winter. If small pots are available, the best method is to place one cutting in each pot, where they may remain until the spring, when they should be potted into 5-inch pots. Heliotropes, Fuchsias, Coleuses, Iresines and Lobelias may be propagated at a later date and placed in a close, cool pit.

The Rock Garden.

Hardy Cyclamen.—Most of these may be sown now in pans of sifted soil, placing them in a cool pit, where they should be protected from strong sun. When large enough to handle, they may be transplanted into boxes, allowing 2 inches between the plants. Most Cyclamen are well adapted for the rock garden, enjoying warm, sheltered nooks with partial shade and shelter from cutting wind. Good drainage is necessary, for, although they enjoy plenty of moisture at the roots, they will not thrive in stagnant places.

Campanulas.—Many varieties of these are suitable for the rockery, and may be increased by division after flowering or by seeds, which can be sown in the spring. The alpine species have obvious advantages for all kinds of rock gardens, being, as a rule, easy to cultivate.

The Hardy Fruit Garden.

Strawberries.—No time should be lost in preparing the ground for new plantations of Strawberries. That which has been occupied by early Peas or Potatoes will suit them well, but to obtain the best results the ground should be trenched to the depth of 2 feet and a good dressing of decayed manure given. When the ground has been allowed time to settle, the surface ought to be carefully broken up, in order to destroy the numerous small weeds which are certain to appear. When the young plants are well rooted, they should be carefully planted and the soil about the roots made firm as planting proceeds. The space between the rows must depend to a certain extent on the varieties selected, but for such varieties as Royal Sovereign 30 inches between the rows is not too much. Other good varieties should include Countess, Dr. Hogg, British Queen, Givon's Late Prolific, Laxton's Latest and Waterloo.

The Kitchen Garden.

Seakale.—This crop is growing freely, and may receive immediate attention to the removal of side shoots, which, if left, will reduce the size of what should be a strong single crown. After this has been accomplished, the ground can be carefully hoed and a dusting of soot given.

Lettuce.—Make frequent small sowings of Lettuce from now to the end of August, and transplant part of the seedlings for succession. Dickson's Monument, a new Cabbage Lettuce of recent introduction, is well worth a trial. Mammoth White Cos is also good for this sowing.
Royal Gardens, Windsor. JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Celery Fly.—At this season the Celery fly is often very troublesome, and means should be taken to prevent it spreading. For this purpose frequent dustings of soot applied on fine mornings are usually effective. This, however, must not be overdone, otherwise more harm than good will result. Where leaves are badly affected, they had better be collected and burnt.

Onions.—The preparation of the ground for the sowing of autumn Onions should be attended to without delay. If the ground has been previously manured for an earlier crop, all that will be required is to have the soil deeply dug and left in a rough state until the time for sowing, which should commence in about a fortnight. Meantime collect some wood-ashes and soot, to be applied to the surface when breaking down the soil for the seed-bed.

The Flower Garden.

Herbaceous Borders.—By this time many of the earlier-flowering subjects will have passed out of bloom. The faded flowers and stalks should be removed; indeed, the borders will require almost daily attention now. Later-flowering plants will require good supports against wind and heavy rainstorms, which sometimes play such havoc at this season.

Dahlias.—These will now be growing freely, and as the shoots are so easily broken off by

wind, they must be supported by looping them up to the central stake. This is a much safer plan than placing a string all round them. Should, however, extra large blooms be wanted, the shoots must, of course, be thinned out and artificial feeding be given occasionally.

Antirrhinums.—These showy bedding plants, which are now giving such a wealth of bloom, should have the old flowering shoots removed, when the laterals will throw up and give a second crop of bloom till well on in the autumn. This cutting away of the faded flower-spikes is most important, as, if allowed to run to seed, the blooming period is very much curtailed.

Planting Daffodils.—The bulbs that were lifted earlier in the season will now be quite ready for planting—that is, if the ground is available. There is nothing gained by keeping them longer in a dry state. Any ordinary garden soil will suit them, but on no account use fresh manure.

Rock Garden.

Helianthemums.—These are now giving a glorious display in the rockery, and some bold clumps placed at intervals on the higher parts of the rockery here are very effective indeed. I find they can be easily propagated by cuttings put in any time after this date. The earlier they are put in, the better plants will they make by the autumn. Insert the cuttings in a cold frame and shade from bright sunshine, and the earliest of them will be ready for planting out permanently in the autumn.

Lithospermum prostratum.—This is another rock plant that can be propagated by cuttings at this season. I find, however, it does not root so readily as the Sun Rose; but if ever a plant was worth tending carefully, then it is this Heavenly Blue, so aptly named. Insert the cuttings in pans, and place them in a cool house or frame where they will have a certain amount of shade for a time.

Plants Under Glass.

Hydrangea hortensis.—Cuttings of this useful greenhouse plant may still be rooted, but at this date it would be advisable to place these in a warm pit, so as to hasten growth before the winter. Those rooted earlier should be potted on and placed in frames, and, when sufficiently hardened, the lights may be entirely removed.

Arum Lilies.—Where these have been ripened in pots, they should now be shaken out and repotted. Place them in their flowering pots at once, using a fairly rich compost. Those that were planted out in trenches should not be potted up until they have made a fair amount of young growth.

Calceolarias.—Prick out the seedlings when large enough to handle, for, as already pointed out, they must on no account be allowed to become drawn. After being pricked out, place them again in a cold frame and shade during bright sunshine. A sharp look-out must be kept for green fly, which usually makes its appearance during hot weather, for, if once allowed to get a hold, the young plants will be crippled at the very outset.

Humea elegans.—The earliest-sown batch should now be ready for pricking out. Place the seedlings singly in small pots and stand them in a cool house where they will get abundance of light and air. Water very sparingly.

Fruits Under Glass.

Late Muscat Grapes.—Should the weather be inclined to be cold and damp, a little warmth ought to be maintained in the pipes, with a free circulation of air day and night. Examine the berries from time to time to see they are not splitting, which is usually caused from too close an atmosphere, and, if this is observed, reduce the moisture in the house and ventilate freely. Draw aside some of the foliage to expose the bunches to the sun, as every means should be taken to have the Grapes well coloured by the middle of September.

Strawberries.—The earliest runners should now be potted into their fruiting pots and stood on a hard surface where they will be exposed to the sun. Water carefully at first, and keep runners cut off as they appear.

Hopetoun Gardens, South Queensferry, N.B.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SUNFLOWER TO NAME (R. S.).—The Sunflower referred to is probably *Harpalum rigidum*, which will grow practically anywhere. Epsom salts is not a cure for slugs.

SWEET WILLIAMS DISEASED (W. E. M.).—The plants sent were too far gone to permit us to say anything about them with certainty. Perhaps you could send others less far advanced in disease than these.

RUST ON VIOLAS (Viola).—The fungus on the Viola is called *Puccinia Algra*. Plants once attacked are generally useless, and are best rooted out. The neighbouring plants may be protected by spraying them with a rose red solution of potassium permanganate.

SWEET PEAS FAILING (W. B. B.).—The material sent is insufficient to enable us to form any accurate idea of the disease from which the Sweet Peas are suffering. The best thing to do, we think, will be to water them with a solution of half an ounce of potassium sulphate to the gallon of water.

A DISEASED PHLOX (Peach).—The Phlox plants are attacked by the stem eelworm. It is not easy, and probably not possible, to cure plants when once attacked by this pest, and we think you would be well advised to propagate only from quite healthy plants and destroy the others, treating the ground they occupy with sulphate of potash at the rate of 2oz. to the square yard. The Peach is attacked by silver-leaf, and we recommend you to root it out and plant another in its place.

PÆONIES REVERTING (R. G.).—We do not recall any instance of Pæonies reverting to the typical species, though there is not the least reason why these, as well as other plants, should not be given to "sport," i.e., produce colour variations quite distinct from the normal, though instances of such are rare. What you refer to, if it has really happened, may be of this kind, or in the nature of deterioration, which we could only say with knowledge of the individual examples. If the whole of the flowers on any plant appear to have gone from pink to magenta, we should be inclined to regard it as due to lack of cultivation; hence deterioration. If, on the other hand, a solitary flower only in a clump had changed, we should look upon it as a "sport," to prove which it would be necessary to mark the branch and later lift the clump, divide and single it out, and replant to prove. It would probably take three years to again reach a good flowering stage. We make no charge for answering queries relating to gardening affairs, and find pleasure in assisting our readers so far as we can.

PROPAGATING GAILLARDIAS (C. W. G. S.).—Apart from seeds, these plants may be increased by cuttings and root cuttings, the latter only practical during the winter months. Cuttings of young shoots may be inserted any time when procurable during the coming weeks, and you had better proceed by pruning back all flowering shoots to their bases and await the coming

of fresh non-flowering shoots, detaching these when 3 inches long with a heel from the parent stem. A cold frame or under cover of a hand-light will be found the best place, using very sandy soil. Cuttings made in the ordinary way to a joint are also useful, and both methods are worth a trial. If you do not succeed with cuttings, write us in the early autumn, and we will endeavour to give an article on root propagation.

TREES AND SHRUBS.

RHODODENDRONS SUFFERING (Ryde).—The Rhododendrons are suffering from something wrong at the roots. Either dryness or perhaps presence of lime in the soil has affected them, and the damage the roots have suffered has caused a check to the leaves. If the plants are well watered, they may grow out of it, provided no lime is present. Lime is fatal to these plants.

WISTARIA LEAVES FOR INSPECTION (Sybil Waller).—Earwigs may have been responsible for the condition of your Wistaria leaves, though we are disposed to think that caterpillars may have been the culprits. All that you can do is to spray the leaves with an arsenical wash, which will kill any insects as they feed. Such a wash may be prepared by mixing 2oz. of Paris green in 25 gallons of water and using it as a spray in fine weather. The chemical should be mixed in a little water before the bulk of the water is used. Early morning is the best time to apply such a spray. Wistarias give quite good results on pergolas, and are often grown in that way. Your plants will probably grow quite vigorously presently.

ROSE GARDEN.

CATERPILLARS ON ROSES (Jeans).—The caterpillar is that of the feathered thorn (*Himera Pennaria*). It is a "looper," and feeds on Oak, Plum and Rose. When it becomes a pest, it may, like most caterpillars, be checked by spraying with lead arsenate.

CLIMBING ROSE NOT DOING WELL (Amateur).—We fear you have rather overwatered the plant, which has somewhat checked the root action. It is better to give such Roses one or two good soakings, then mulch, than apply water too frequently in dribbles. Have the ground forked up; then put in 2 inches or 3 inches of well-decayed manure and leave it alone.

INJURY TO ROSES (Rev. R. F. C.).—We think the damage to the Roses is not due to the manure used, but rather to some insect, probably a species of bug, which has punctured the young growths. You will probably find an insect very similar in shape to the cuckoo-spit fly, which is so common, but not living as that does in a sort of spittle. It is this insect that does the damage.

CLIMBING ROSES FOR A RED WALL (H. F.).—As your house wall is red, you cannot do better than plant Mme. Alfred Carrière (white) and Rêve d'Or (creamy yellow). See that the soil is dug at least 2 feet deep and plenty of manure given to the lower soil. When planted, the Roses should be given some water, and when established they would need water and liquid manure twice a week from May to August, the liquid manure being given at each alternate watering.

ROSES FOR PERGOLA (M. M. K. C.).—We think a beautiful effect would be obtained from your pergola 77 feet in length if you planted the following ramblers that would bloom somewhere about the same time. If you preferred, you could start with the colours in the order named, or blend them to your own taste. Cream and orange—Aviateur Blériot and Shower of Gold. White—White Dorothy and Lady Blanche. Blush—Lady Godiva, Débutante and Sweetheart. Pink—Chatillon Rambler. Rose—Minnehaha. Red and crimson—Sodenia, Excelsa and Hiawatha.

CLIMBING ROSES FOR SOUTH WALL (H. P. B., Bristol).—You can obtain plants in pots now and plant them out at once. Ask for extra strong plants in 8-inch pots. Those grafted this year that have been hardened off would be best. You should dig the border to a depth of 3 feet, and work plenty of manure into the lower soil, together with some basic slag, at the rate of 6oz. to a square yard. Bury this and the manure 2 feet below the surface. When planting Roses, turn them out of their pots carefully, and, before putting on the final soil, scatter a handful of bone-flour around the plant. Water plentifully during the dry weather, and it will be as well to cover the surface soil with some very old manure, not strawy stuff; or, failing this, some spent Hops from a brewery—about 2 inches or 3 inches thick of these. You can then water over them, and the Hops will preserve the moisture in the soil better. Half-a-dozen good kinds would be Climbing Lady Ashtown, Florence Haswell Veitch, Rêve d'Or, Mme. Alfred Carrière, William Allen Richardson and Climbing Richmond.

GRAFTING CLEMATIS JACKMANNII AND OTHERS ON CLEMATIS VITALBA (Clematis).—It is not usual to graft the varieties of Clematis Jackmannii and other kinds upon vigorous plants of *C. Vitalba*, neither would such an operation be desirable, for the stock would be certain to send out strong shoots and destroy the weaker grafts. When grafting is resorted to, sections of roots of *C. Vitalba* 3 inches or 4 inches long are taken in the spring (February or March), and upon them soft shoots of the varieties, taken from plants which have been forced into growth, are grafted. Each piece of root with graft attached is then potted singly into a 2½-inch pot and stood in a moist, warm and close frame until both young roots and young shoots are formed. Cuttings may be rooted of the kinds you name if they are inserted at once in sandy soil in a close frame.

THE GREENHOUSE.

SCHIZANTHUS TO GROW (E. F. C.).—Schizanthus should be sown about August 15 in a cold frame in pots, but the seedlings should be potted (as soon as they are large enough to handle) into 3-inch pots singly and returned into the cold frame. As soon as the plants are about four inches high, pinch their tops off; this will induce the growth of many side branches, causing the plants to become bushy. A fortnight afterwards pot into 4-inch pots, and then place on a shelf in the coolest end of a greenhouse where it can have abundance of light and plenty of air when the weather is favourable. Stop the shoots again in spring about the end of March, and a fortnight afterwards shift into their flowering pots (6-inch). The chief secret of success in the growth of this plant is to keep it always in a cool, airy atmosphere. Heat and overcrowding are fatal to its success.

PROPAGATING IMPATIENS OLIVIERI (A. B. P.).—The best time to propagate *Impatiens Olivieri* is during the spring months, but it is not at all a difficult subject to strike, and cuttings may be put in even now. The best cuttings are formed of the points of young growing shoots, taken off at a length of about three inches. A few of the bottom leaves having been removed, the cuttings should be dibbled into well-drained pots well filled with fine sandy soil. Then a good watering must be given through a fine rose in order to settle everything in its place. After that place the pots in a close propagating-case in a gentle heat, such as is used in the increase of Fuchsias, Heliotropes and other soft-wooded plants. Under these conditions the cuttings will soon root, when they must be gradually hardened off and potted singly into small pots.

SWEET-SCENTED FLOWERS IN A GREENHOUSE (H. D. M.).—There are a considerable number of sweet-scented flowers available for the decoration of the greenhouse or conservatory at different periods of the year. Prominent among them are bulbs of different kinds, of which the Freesias, Roman Hyacinths and Paper-White Narcissi should be potted as soon as they are obtainable, which will be, as a rule, during the first half of August. The Roman Hyacinth is often referred to as needing to be forced, but bulbs potted in August in a greenhouse temperature will flower by Christmas. Later on come the other kinds of Hyacinths, different Polyanthus Narcissi and the Lily of the Valley. Lilies, too, are very desirable, the best for pot culture being *Lilium longiflorum* or its variety *Harrisii*, whose long, silvery white trumpets are very beautiful and sweetly scented. *L. auratum* has a more pronounced fragrance, which is admired by some. The perfume of *L. speciosum*, which is such a handsome Lily, is less marked than in those previously mentioned. Of these Lilies, the first to flower in the early summer is *L. longiflorum*, then *L. auratum*, and afterwards *L. speciosum*. The retarding of bulbs which now prevails has, however, so upset the seasons that flowers of these Lilies may be had all the year round. In any selection of sweet-scented bulbous plants *Tuberoses* must, of course, be included. Of shrubby plants that flower during the winter and early spring may be specially mentioned the deliciously fragrant *Daphne indica* and its white variety *alba*; *Boronia megastigma*, whose Violet-like perfume is of a very penetrating nature; and *Luculia gratissima*, with large, Hydrangea-like heads of blossoms. This last, however, requires a good-sized structure for its development. Soon after these comes *Cytisus racemosus*, also known by the specific name of *fragrans*. Some *Cyclamens* are also sweetly scented, while the most pronounced of the *Primulas* in that respect is the Abyssinian *P. verticillata* and *P. kewensis*. The flowers of *Rhododendron Edgeworthii* and some of its progeny, such as *fragrantissimum*, *sesterianum* and *Lady Alice Fitzwilliam*, are also very fragrant. These all bloom in the spring. Some of the *Carnations*, too, are very valuable, but can scarcely be expected to give of their best unless there is a house specially set apart for their accommodation. During the summer months you may have the *Daturas* or *Brugmansias*, with their long, trumpet-like, white blossoms; *Heliotrope* or *Cherry Pie*, admired by everyone; *Magnolia fuscata*, whose dull brownish flowers suggest Pineapple drops; the different hybrid *Nicotianas*, especially those raised from *N. affinis*; and the delicious Jasmine-like *Bouvardia Humboldtii corymbiflora*. *Humea elegans*, with its upright feathery panicles of reddish flowers, is very ornamental, but its attractive fragrance is chiefly with the flowers. Of climbers, two that can be specially recommended are *Rhynchospermum jasminoides* and *Jasminum grandiflorum*. Both flower during the summer, but the last named is later in blooming than the other. The large double German Wallflowers will, if sown in June and July, bloom quite early in the year. The flowers are deliciously fragrant, as also are those of the dull purplish-coloured *Cheiranthus kewensis*, which bloom throughout the winter. Stocks are so beautiful and fragrant as to merit a note to themselves. The tall-growing *Beauty of Nice* may be had in bloom in the winter as well as in the summer; while, by varying the time of sowing, the *Ten-Week*, *East Lothian* and intermediate varieties may be had in flower throughout the greater part of the year. Among the different subjects remarkable not for the fragrance of their flowers, but of the foliage, may be mentioned the *Lemon Verbena* (*Aloysia citrifolia*), a universal favourite, which is fairly hardy in many parts of the country; and the *Myrtle*, of which much the same may be said, and also a valuable evergreen for growing in large pots or tubs. Scented-leaved *Pelargoniums*, too, which are certainly more popular now than they were a few years ago, are very dissimilar from each other, not only in general appearance, but also in their perfume, for the pronounced scents of *Lemon* and *Peppermint*

are present among them, as well as many of their own. The Apple-scented Sage (*Salvia rutilans*) is another that can be recommended for its fragrance, while the scarlet blossoms are also very showy. Lastly, there are the different forms of *Boronia*, a class of South African Heath-like shrubs with very aromatic foliage, and the citron-scented member of the Blue Gum family, *Eucalyptus citriodora*.

QUESTIONS ON VARIOUS PLANTS (Harrogate).—1. *Begonia Gloire de Lorraine* may be flowered the second year, but it is more satisfactory when grown on annually from cuttings. Old plants that it is intended to keep should be cut partially back after flowering, and then, as soon as young shoots are pushed forth, be repotted in a mixture of loam, peat and sand. If your plant has not been touched in any way, it will now be too late to prune it, but it may be repotted, using a larger pot if necessary. 2. The cause of the leaves of your *Asclepias* turning yellow is no doubt owing to the plants being more or less starved. As they have been flowering since the spring, the pots will now doubtless be full of roots, in which case the plants will be greatly benefited by an occasional dose of some stimulant or by being shifted into larger pots. 3. *Bouvardias* of all kinds are shrubs, and therefore perennials. 4. The *Watsonias* are a genus of South African bulbous plants nearly related to the *Gladiolus*. They should now be flowering, or nearly approaching that stage. At this time they will need plenty of water, but in the winter, when dormant, must be kept quite dry. 5. There are several possible reasons for your Ferns turning yellow as described, but without inspection one cannot feel very safe in giving an answer. In the first place—and that a very probable cause—the atmosphere of the house may be too dry, as, even if the house is shaded by Summer Cloud, this is very likely to happen in hot weather. The heat and dryness of the atmosphere will encourage the increase of such insect pests as red spider and thrips, which will soon disfigure the fronds. You say the plants are not over-watered, but there is just the possibility that they have been kept too dry at the roots. A golden rule to observe in the successful culture of Ferns is that they enjoy a considerable amount of humidity in the atmosphere. 6. If the *Aubrietias* are trimmed over with a sharp pair of scissors, they will form dwarf plants for another season. Should it be desired to increase them, they can, as soon as they recover from the cutting over, be divided and planted out in a prepared bed. If it is desired to keep *Violas* over the second year, they must be trimmed when they begin to look shabby, not after the middle of August. This will lead to the production of a considerable number of young shoots, some of which may, if required, be taken off as cuttings and inserted in a shady border. Some of the *Antirrhinums* and *Sweet Williams* will flower after the second summer, but they cannot be depended upon like young plants.

FRUIT GARDEN.

ABOUT RASPBERRY CANES (Devonia).—We do not find any insect on the Raspberry canes sent, and think they have possibly been damaged by forking among them too deeply.

AMERICAN GOOSEBERRY MILDEW (Mrs. McD.).—The Gooseberries are badly attacked by the American Gooseberry mildew. You must report it to the Board of Agriculture. Spraying is, we fear, of little use. But the bushes should have all the young growths (on which the fungus is likely to be present) removed in the early autumn.

INJURY TO PEAR AND PEACH TREES (H. H. G.).—The Pear fruits appear to have been injured by cold. Probably a frosty night occurred either when the trees were in flower or soon afterwards. The leaves of the Peach are injured by Peach leaf-curl. The curl is due to the presence of a fungus (*Exoascus deformans*). Collect and burn all affected leaves to keep the disease from spreading. It is as well to remove the ends of the affected shoots below the highest good leaf, as the fungus grows into the leaf-buds near where it is present, and rests there for another year.

MEALY BUG, MILDEW AND SPIDER ON VINES (Troubled).—One of these is bad enough at a time, but the three together is no joke. For mildew and spider, the best thing you can do is to dredge your Vines heavily with flowers of sulphur, leaving it on for thirty-six hours. Spray the Vines over lightly in the evening before applying the sulphur, and keep the vinery extra warm while the sulphur is on. Use rain-water for spraying, and also for syringing off the sulphur at the end of the thirty-six hours. As regards mealy bug, your best chance of eradicating it at this time of the year is to use Bunyard's Blight Cure No. 1, from Messrs. George Bunyard and Co., Royal Nurseries, Maidstone. Apply with the brush. With perseverance you may keep it down in this way.

HOW TO GROW MELONS IN A FRAME (E. C.).—Make up a hot-bed 15 inches all round larger than the frame and 2½ feet deep. Tread it down firmly. Stand your frame on it as soon as it is made, keeping the light off for a week or ten days afterwards to let the rank steam escape out of the manure. At the end of this time place in the centre of the frame some sods of turfy loam, grass side downward, covering 2 square feet of the bed. On the top of this place a bushel of loamy soil, broken up into pieces the size of a hen's egg. Use the small with it as well. Make this into a mound or cone on the top of the sods spoken of above, and tread firmly. The top of this mound of soil should be a foot from the glass. Drive a stick into this to test the heat of the bed, and let it remain in for two days. Take it out then and feel with the hand. If it feels hot, you must not plant the Melons

until the heat has subsided. If, on the other hand, the stick is only moderately warm, you may plant at once. Place two plants in the middle of the mounds about four inches apart. As soon as the plants have made four leaves pinch the heart out of each plant. You will find they will then form side shoots. Select two of the strongest of these and pinch the others off, and let them grow without stopping until they are each 2 feet long, trailing them on the ground (or the face of the border).

THE APPLE SAWFLY (St. C.).—The Apples are attacked by the Apple sawfly. The fruits attacked will soon fall, and all should be burned as quickly as possible, so as to reduce the risk of the sawfly spreading in future years. Spraying of any kind is not a certain cure for the pest, for the fly lays its eggs either in the bud or in the open flower, generally the latter.

GRAPES BADLY MILDEWED (E. M. H.).—The only effective way of killing mildew on Vines when once it has obtained a stronghold, as it seems to have done in your case, is to spray the Vines thoroughly with rain-water, and then to dredge every part with flowers of sulphur. Leave it on for three days and then blow off with a powerful pair of bellows. Late in the afternoon is a good time to apply the sulphur.

PLUM TREES NOT FRUITING (Leicester).—Seeing that your Plum trees are still making only wood growth, in spite of the root pruning to which you say they have been subjected, we can only conclude that your soil must be over-rich, and also deficient in lime. Stone fruit will not succeed in limeless soil. Root prune again, but not too severely, as soon as the leaves have fallen, and add half a bushel of lime to the soil of each tree, well mixing it with the soil before applying.

INJURY TO APPLE TREE (Bruin).—The Apple is attacked not by a fungus or a mildew, but by an aphid, the stem aphid of the Apple, *A. Fitchii*. We recommend a thorough spraying with Quassia and soft soap, or with a nicotine compound. A suitable Quassia and soft soap wash may be made by simmering or gently boiling 1lb. of Quassia-chips in water for a couple of hours. Dissolve half a pound of soft soap in warm water and stir in the strained-off Quassia extract; then add sufficient water to make up ten gallons.

SHOT-HOLE FUNGUS IN PEACH TREE (A. J. B.).—Your Peach is attacked, apparently, by one of the shot-hole fungi, but as the fungus is not yet fruiting it is impossible to say which one. We fear all the leaves showing this spotting will drop in any case, and recommend you to spray the tree with ammoniacal copper carbonate, made by mixing 5oz. carbonate of copper into a paste with water, adding three pints of strong ammonia, and diluting the deep blue solution so obtained with water to make forty-five gallons. Make the solution in a wooden vessel.

GRAPES SCALDED (W. B. L.).—The sample of Grapes sent are badly "scalded." This is a term applied to Grapes which appear as if they have been scalded or parboiled. Scalding is caused through late or imperfect ventilation on bright sunny mornings while the Vines, and even the berries, are saturated with moisture. To stop any further mischief, have a little heat in the hot-water pipes and ventilate more freely, leaving a little top and bottom air on all night while the weather is warm, but top air only at night when the weather is cold.

KITCHEN GARDEN.

CABBAGE ROOT MAGGOT (York).—The stocks appear to have been attacked by the Cabbage root maggot. This cannot be cured, but seedlings may be protected to some extent by putting sand moistened with paraffin about the bases of their stems early in their growth.

MISCELLANEOUS.

FUNGUS ON AZALEA (J. McE.).—The fungus is *Exobasidium japonicum*. It has only recently appeared in this country, but is becoming quite common. The galls it produces should be picked off and burned.

INSECT PESTS (H. S.).—Dip the *Begonias* in the soft soap and sulphur wash we have frequently recommended for the plants. The Turnips are badly attacked by the diamond back moth larvæ, and we recommend you to dust them immediately with soot and lime or spray them with arsenate of lead.

WORM TO NAME (Curculio).—The creature sent is not an insect, but a worm which lives inside insects, such as ground beetles and the like. It leaves the bodies of these insects at a certain stage of its career, and lives for a time in the open air, but is quite harmless to plants and man. It is known as *Gordius*.

WEED SPREADING IN WOODS (Mrs. P.).—The specimen sent for identification is the Gout-weed (*Ægopodium Podagraria*). It is one of the most difficult weeds to eradicate once it has been allowed to become well established. The best method to adopt is to fork out the weed as much as possible; then, as young shoots appear above ground, keep them hoed down before the leaves have a chance to develop. By this means the weed may be gradually destroyed.

EXAMINATIONS IN HORTICULTURE (R. R.).—The principal examinations in horticulture are those instituted by the Royal Horticultural Society. They are those for the National Diploma in Horticulture, the General Examinations for all classes of gardeners, the Parks' Employés Examination for those employed in public parks, &c., and the Teachers' Examination for teachers in schools. Full particulars of these may be obtained on application to the Secretary, Royal Horticultural Society, Vincent Square, London, S.W.

NAMES OF FRUIT.—Mrs. Mamell.—The Peach was rather damaged, but we think it is Hale's Early.—*M. P.*—Black Muscat Grape.

NAMES OF PLANTS.—E. B.—*Stachys lanata*.—*Mart.*—*Ligustrum lucidum*.—*E. E. S.*, *Stoke Poges*.—*Clematis recta*.—*A. B.*—Flowers dropped and shrivelled, but probably *Begonia Corbeille de Feu*.—*Fulbourne*.—1, Spanish Broom (*Spartium junceum*); 2, *Veronica incana*; 3, *Æthionema pulchellum*; 4, *Asperula tinctoria*; 5, *Arenaria montana*.—*J. M.*—1, *Linaria purpurea*; 2, *Geranium Phœum flore pleno* (Double Dusky Crane's-bill).—*F. Green, Port Elizabeth*.—A very fine form of *Nephrolepis cordifolia*.—*S. H. B.*—*Pontederia crassipes* (Water Hyacinth).—*Alfred Althusen*.—*Sambucus racemosa*.—*R. K. H.*—*Echium vulgare* (Bugloss).—*F. E. Walsh*.—1, *Paulownia imperialis*; 2, *Olearia Haastii*; 3, *Choisya ternata*.—*W. W. B.*—*Pyrus Aria* (White Beam).—*A. Smith*.—*Linnaea borealis*.—*Seeker*.—1, *Galega officinalis* and the variety *alba*; 2, *Melissa officinalis* (Balm); 3, *Euphorbia Lathyris* (Caper Spurge).—*M. P.*—The plant is *Helxine Solierii*.

SOCIETIES.

NATIONAL ROSE SOCIETY.

THE provincial show of this society was held in the Sydney Gardens, Bath, on the 16th ult. The recent rainfall had certainly improved the quality of many Roses exhibited, and the show, as a whole, was a most excellent one for so trying a season. There was a good attendance of visitors throughout the day. The large marquee was delightfully cool, owing to its erection in a particularly favourable position.

NURSERYMEN.

The Jubilee Trophy and gold medal, offered for thirty-six blooms, distinct varieties, of exhibition Roses, were secured by Messrs. Alex. Dickson and Sons, Ledbury, with a well-finished stand, including excellent blooms of *Mme. Maurice de Luze*, *Her Majesty*, *Lohengrin*, *Frau Karl Druschki*, *Mrs. A. E. Coxhead*, *Helen Keller*, *Mildred Grant*, *Claudius*, *H. V. Machin* and *Tom Wood*. The second place was secured by Messrs. Frank Cant and Co., Colchester, who also staged some very good flowers, the finest blooms being *Mrs. Joseph H. Welch*, *Maman Cochet*, *Prince Arthur*, *Mrs. Foley Hobbs* and *Mme. Jules Gravereaux*. Messrs. Hugh Dickson of Belfast were placed third.

The Mayor's Cup, offered for seventy-two blooms, distinct, was also carried off by Messrs. Dickson, Ledbury, with an equally effective stand of well-developed blooms. They also led the way with twenty-four varieties, distinct, including *Lady Barbara*, *Mrs. David McKee*, *Countess of Derby*, *Duchess of Sutherland*, *Lady Ashtown*, *Bessie Brown* and *Mabel Drew*.

Mr. Harry Drew, Longworth, Berks, obtained the highest award for thirty-six blooms, distinct, the best flowers being *Mme. Eugène Verdier*, *Avoca*, *Ulrich Brunner*, *Suzanne M. Rodocanachi*, *Frau Karl Druschki*, *Earl of Gosford*, *Mildred Grant*, *Florence Pemberton*, *Hugh Dickson*, *George Dickson* and *Dean Hole*. *Mr. George Prince*, Oxford, was second.

Mr. Drew again scored for sixteen distinct varieties, three blooms of each.

For twenty-four blooms, distinct varieties, *Mr. John Mattock*, Headington, Oxford, was to the fore, his blooms of *Ethel Malcolm*, *British Queen*, *Edward Mawley* and *Earl of Warwick* being excellent in every respect. *Mr. Charles Turner*, Slough, was a good second, showing *George Dickson*, *Frau Karl Druschki*, *Mrs. Foley Hobbs* and *Helen Keller* in good form and colour.

Mr. John Mattock was again first for eight distinct varieties, three blooms of each; second, *Mr. Ernest Hicks*, Wallingford; third, *Mr. C. Green*, Hitchin.

Mr. Henry Drew secured first place for eighteen blooms, among which the following were in good form: *Mme. Jules Gravereaux*, *Molly Sharman Crawford*, *Mme. Leon Constantin*, *Comtesse de Nadaillac* and *Alexander Hill Gray*. *Mr. George Prince*, Oxford, followed closely with a well-finished stand.

Mr. John Mattock led the way with eighteen blooms, distinct, *Mr. Ernest Hicks* being second.

OPEN CLASSES.

Mr. George Prince secured first place for twelve blooms of new Roses, distinct, including *Mabel Drew*, *Mrs. J. Welch*, *Elizabeth*, *Mrs. W. K. Rowe* and *Mrs. Cornwallis West*, Messrs. Hugh Dickson, Limited, Belfast, coming second, and Messrs. Alex. Dickson, Ledbury, third.

For twelve blooms of any new Rose, *Mr. Elisha J. Hicks* was a good first with *Mrs. G. Norwood*, which he staged in splendid condition, Messrs. Alex. Dickson coming second with *George Dickson*, and *Mr. J. Mattock* third with *British Queen*.

For twelve blooms of any Hybrid Perpetual, *Mr. H. Drew* and Messrs. Alex. Dickson were awarded equal first, *Mr. Charles Turner* coming third.

For twelve blooms of any Rose other than Hybrid Perpetual, Tea or Noisette, Messrs. A. Dickson secured first place, *Mr. C. H. Green* second, and *Mr. J. Mattock* third.

For twelve blooms of any Tea or Noisette Rose, *Mr. H. Drew* secured first, *Mr. J. Mattock* second, and *Mr. G. Prince* third.

For twelve distinct varieties, three blooms of each, Tea and Noisette Roses, *Mr. George Prince* secured first prize, and *Mr. H. Drew* second.

PERPETUAL-FLOWERING DECORATIVE ROSES.

For five baskets of cut Roses in distinct varieties, *Mr. George Prince* was awarded first prize, *Mr. H. Drew* coming second, and *Mr. J. Mattock* third.

THE GARDEN.

No. 2229.—VOL. LXXVIII.

AUGUST 8, 1914.

NOTES OF THE WEEK.

Generous Gift to Reigate.—It is with pleasure that we learn that Sir Jeremiah Colman, Bart., so well known in horticultural circles, has purchased Reigate Hill from Lord Monson and presented it to Reigate, thus ensuring it being an open space for ever. Reigate Hill is one of the most charming spots in Surrey, overlooking a beautiful and typical stretch of English landscape. The gift is to commemorate the jubilee of the Reigate Corporation, which was inaugurated in 1863.

A Little-Known Rock Garden Plant. In *Bellium bellidioides*, a miniature plant known by the name of the False Daisy, we have one of the most charming subjects for the rockery, and yet it is a plant very seldom met with. The small rosettes of dark green spatulate leaves form quite a dense mass, above which rise the small, fairy-like Daisies in great profusion, and about two inches high, the whole summer through. It was introduced in 1796 from the Mediterranean region, and requires an open, sunny position in well-drained, stony soil, where the little stolons, about an inch long, which it continues to send out, can ramble freely and root, when it will soon make an attractive little colony. It is readily raised from seed or by division.

Pink Mallows in the Garden.—One of the most attractive hardy annuals in the garden just now is the pink Mallow, or *Lavatera rosea splendens*. We have it growing in association with the white Phlox Mrs. E. H. Jenkins, and the combination is as perfect a colour harmony as one could wish. Last year we remember seeing it growing between white Japanese Anemones, when the effect also was very pleasing. This pink Mallow is an annual to make a note of now, so that it may be included in the next seed order for sowing next spring. The seeds can be sown outdoors, but the seedlings need plenty of room and fairly good soil.

The Night-scented Stock.—During the past few weeks we have derived so much pleasure from this little-known annual that we cannot refrain from writing about it. During the day-time the plant has nothing to commend it, but early in the evening the pale lilac flowers unfold and quickly saturate the air with their delightful fragrance. We have it growing under the windows, where it is about a foot high, and there are few greater joys in the garden than to inhale its fragrance. The seeds can be sown outdoors in spring, and the seedlings do not need transplanting. It is

an annual that ought to be in every garden where fragrance is appreciated.

Sowing Seeds of Alpines.—Many seeds of these interesting plants, such as Primulas, Dianthi, Lychnis, Arenaria and a host of others, should be sown as soon as ripe. Much better results are usually obtained than if the seeds are left till the spring, as they germinate more quickly and evenly. This also applies to many of the monocotyledons, such as Lilies, Eremuri, Irises and similar plants.

cinum. The flowers are large, golden, almost butter yellow, and appear in profusion for many weeks.

Important Notice to Our Readers.—A correspondence has been taking place in the columns of the *Advertiser's Weekly* and the *Nurseryman and Seedsman* regarding the bona fides of certain of the advertisements which are published in some of the gardening papers. So far as THE GARDEN is concerned, the Proprietors have for some years made it their practice to decline to insert any advertisement as to which there could be the slightest ground for suspicion. The result has been that the readers of THE GARDEN have learned to know that the appearance of an advertisement in THE GARDEN may be regarded as a trade mark of respectability and integrity. We have never yet gone so far as to guarantee the goods supplied by our advertisers, because with the precautions that are taken the necessity has not arisen.

A Good Crimson Rose.—One of the best crimson Roses for the garden, and one that never fails to elicit the admiration of visitors, is Château de Clos Vougeot. Unfortunately, its name is unwieldy for English tongues, but that does not detract from the merits of the flower. It is a Hybrid Tea of moderately vigorous constitution, and the large flowers are dark velvety crimson, shaded with scarlet. They are also fragrant and last longer on the bush than those of any other Rose we know, while the colour is not affected by the strongest sunshine. The only drawback to this beautiful dark Rose is its ungainly habit, the shoots growing at very awkward angles. This can, however, be largely remedied when pruning by cutting to buds pointing upwards.

The Lowberry as a Preserve.—During the last few days we have been testing the fruits of the Lowberry as a preserve, and have been delighted with the excellent jam they make. This has all the good features of Blackberry jam, minus hard cores and most of the seeds. Of

A Beautiful Hybrid St. John's Wort.—We were much charmed with a group of *Hypericum moserianum* the other day. At this season, when few shrubs are flowering and the leaves have not their autumn tints, a bright flower such as this is appreciated. If used as a groundwork for small deciduous, early flowering shrubs, such as Hamamelis, Daphnes or similar kinds, the bed can be made bright for almost the whole year. This beautiful St. John's Wort is the result of crossing *Hypericum patulum* and *H. caly*

course, many seeds are there, but not in anything like the quantities that we find in Blackberry jam. The flavour of the two is practically identical. Though not fruiting so freely as the Loganberry, the Lowberry is well worth a place in those gardens where it can be given plenty of room, preferably rambling over some rough trellis. The fruits are jet black, very juicy and sweet. It needs precisely the same treatment as the Loganberry.

THE FALSE DAISY, *BELLIUM BELLIDIODES*. THIS IS A FREE-FLOWERING PLANT IN THE ROCK GARDEN DURING SUMMER AND EARLY AUTUMN.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Sweet-Scented Rosaries.—In answer to your correspondent's enquiry for a recipe for making beads from Rose petals, she will find a full description of the method in a small sixpenny book called "Perfumes and Cosmetics," by Thomas Bales, F.G.S., and Charles Godfrey Leland. The publishers are Messrs. Dawbarn and Ward, Limited, 6, Farringdon Avenue, London, E.C.—R. DE PREE.

Ivy Growing Without Roots.—In a recent issue a reader asks, "Has anyone ever seen Ivy growing on a building without any root connection?" Yes, I have. In the inner courts of Muckross Abbey—Lord Ardilaun's demesne near Killarney—the Ivy is growing freely on the ruined wall, although the main stem has been cut away

tion as to any garden competitions or flower shows known to your readers in the County of London, and to receive suggestions as to any centres likely to promote in working-class districts the cultivation of gardens.—ARTHUR R. ATHEY, 197, Walworth Road, S.E.

The Judging of Roses.—I was always under the impression that the public were not admitted to flower shows while the judging is going on; but it appears that this is not always followed, even in important exhibitions. The reason I form this opinion is that your correspondent Edwin Molyneux, in THE GARDEN for August 1, writing on "The Most Fragrant Rose," says, concerning the recent award for the "Clay" Cup, that he watched the judges closely all the time they were engaged in adjudicating upon this particular item. Now, if the rules were strictly carried out, how would it be possible to watch every action of the judges unless your correspondent was one of them, which he implies,

the tiny grub lives and feeds until it emerges from the chrysalis as a perfect insect.—E. E. CARTER, Romford.

Maries' Balloon-Flower in the Moraine.—Experiments in the cultivation of certain plants in the moraine are extremely interesting, and it is amazing to see how many subjects which will grow in a border or on ordinary rockwork will flourish much better in the moraine. A trial of *Platycodon Mariesii* in a whinstone moraine with a subsoil of sandy loam is proving quite a gain, as the plant is not only growing well, but is flowering exceptionally freely. This *Platycodon* can, of course, be grown in a border, but there are some who find it short-lived in this position. One cannot tell positively from the results of a short trial, but there is every appearance that *P. Mariesii* will do better in the moraine than in a border here. The gravel keeps the roots cool underneath, and also absorbs and gives off gradually the heat from the sun for the benefit of the foliage and flowers. It is easy to criticise moraine planting, but the results are such as to convince the most sceptical that much advantage will be derived from its practice with many good plants.—S. ARNOTT, Dumfries.

JULY, 3 A.M.

"Flowers only flourish rightly in the garden of someone who loves them."—RUSKIN.

The dew is yet upon the Rose—
Wait! presently the breeze will shake
The blossom open to the morn—
And passing silently will close
The night flower, watching by the lake,
And turn the Lilies towards the dawn.
Carnations then, and Roses sweet,
White Jessamine upon the wall,
Will breathe their tender fragrance out;
And Sweet Peas stretch their wings to meet
The pearly dewdrops, as they fall.

And hidden in these sleeping bowers
I feel ashamed to be awake—
With dreaming foliage all about,
And noise of sticky buds that break.
The very birds are silent yet—
God is alone amongst his flowers:
The paling stars, in trembling state,
About the throbbing skies are set
To bid the eager dawn await. M. C. S.

Hardiness of *Roscoea cautioides*.—This *Roscoea*, which we owe to the enterprise of Messrs. Bees, Limited, is a charming and distinct species, which some have been chary of purchasing until its hardiness was more fully proved or until it became cheaper. I have been following its cultivation with considerable interest, as it is always desirable to know the ways of a new plant as far as possible, so that one may be successful in its cultivation. So far as I can learn, it is probably hardy in at least the less inclement districts of the three kingdoms, and in none of the places in which I have seen it has it failed. In two good gardens in Wigtownshire it has stood the past winter, and is thriving well and has flowered satisfactorily. One plant was in the fascinating garden of Sir Herbert Maxwell at Monreith, where it is in the border. Another was in the rock garden in that delightful Paradise of Logan, in the same county, the home of Mr. Kenneth M'Douall. It was in bloom there at the end of June. This distinct pale yellow *Roscoea* is worth some consideration from purchasers of new plants.—D. A.

LEAVES OF ROSE AIMEE VIBERT, SHOWING THE WORK OF THE LEAF-CUTTING BEE.

2 feet from the soil, and you can pull it away from the wall at the base. Yet the foliage is bright and flourishing. When I saw it years ago it was some 30 feet high and 12 feet to 20 feet broad, in a mass, and what a lovely ride we had through the estate!—GEORGE BUNYARD, Maidstone.

London Gardens Guild.—May I invoke the help of your readers in my endeavour to extend the gardening movement among the working-classes of London? Through the kindly initiative of Mr. Noel Buxton, M.P., the Browning Settlement has established the London Gardens Guild, the aim of which is "To promote the planting and tending of gardens in the working-class districts of London; to encourage existing garden competitions and flower shows; to develop such contests where there are none; to aim at every available patch of ground attached to private dwelling place or place of business being planted with trees, shrubs or flowering plants." The motto of the Guild is: "London a Garden City! Why not?" I should be very glad to receive informa-

tion although he does not actually say, he was not?—AN OUTSIDER.

The Leaf-Cutting Bee and Roses.—I was much interested in the note on page 387 of last week's issue, where "Heather Bell" describes his experience with the leaf-cutting bee and *Pelargoniums*. I am sending a photograph of a spray of Rose leaves taken from the climber *Aimée Vibert*, showing the damage done to the foliage by the leaf-cutting bee. This insect appears to attack some Roses more than others, *Frau Karl Druschki* and other rampant growers seeming first favourites. The bee itself is one of the solitary kind, and is about the same length as the ordinary hive bee, only a little stouter. Her black body is covered with short, brown hairs. Each leaf she attacks is rapidly cut, and the circular piece, held between fore-feet and jaws, is carried to her underground nest. The pieces so gathered are made into tiny thimbles or cells, and in each she places one egg, surrounding it with bee bread. In this leafy home

Shrubs Flowering and Fruiting.—The present is a quite out-of-the-ordinary season for the flowering and fruiting of shrubs. It is the first time *Cæsalpinia japonica* has flowered here, and plants which have produced blooms sparsely in the past, e.g., *Banksia* *Roses* and *Azara microphylla*, have been very profuse of bloom. It is the first time I have seen *Choisya ternata* fruiting, and that on one plant only; also the first time in my experience of *Chimonanthus fragrans* fruiting, though this I saw in a Southern garden, and perhaps it is not uncommon. One specimen of *Azara* here was profusely fruited, but recently the fruits have all disappeared. The garden fruits are extraordinary, Gooseberries and Currants being bent to the ground with the crops, and Apricots, Peaches, Plums and Apples all requiring an amount of thinning far beyond anything I have seen for years. Strawberries are the one sparse crop, and it would seem their failure is general.—R. P. B., *Prestonkirk*.

Rose Zephyrine Drouhin.—In THE GARDEN of July 25, page 375, "W. B. G." expresses a desire for information respecting this Rose, and from my experience I am convinced that more than your correspondent require information regarding it. My attention had not been called to this Rose till last summer, when a lady member of the family here returned from a visit to some English friends, where she had seen a bloom of it in a gentleman's button-hole, and was high in its praise, adding that "we must have it." I accordingly purchased four plants of it from a well-known English Rose-grower, and planted them in good positions. Meanwhile another plant of the same variety was received from a different source. As blooms developed on my quartet I was rather disappointed to find them small in size, rather globular in form, of a rather washed-out pink shade, and very ephemeral. I was about to express my disappointment to the young lady when she declared that the firm had not supplied the proper article, and backed up her assertion by reference to a vase filled with blooms of what she declared to be the true *Zephyrine Drouhin*, beautiful indeed, and far removed from those borne on the plants of my purchase. This led me to examine the single specimen received from another source, which had been overlooked, and this proved the correctness of the young lady's contention. But this is not all. I now looked up the list of the grower from whom I had purchased the quartet, and found *Zephyrine Drouhin* described as a "shell pink." I next looked up the list of a noted Continental Rose-grower, and found it there described as a "rosy crimson," and you now, Sir, describe it as "carmine pink." I, too, should be glad for information respecting the colour of *Zephyrine Drouhin*. The two so-called *Zephyrine Drouhins* we have here, while differing in foliage and flower, are both thornless.—CHARLES COMFORT, *Midlothian*. [The colour of this Rose is described by the National Rose Society as bright carmine pink, and this, we think, is the best description that can be given. The stems are mostly green and thornless, and the blooms very fragrant.—ED.]

FORTHCOMING EVENTS.

August 10.—United Horticultural Benefit and Provident Society's Committee Meeting.

August 11.—Royal Horticultural Society's and National Gladiolus Society's Combined Show at Vincent Square, Westminster.

August 13.—Flower Show at Taunton Dene.

ROSE-GROWING IN TOWN GARDENS.

THE advancing season has given us further opportunities of estimating the merits of our new *Roses*, as well as of confirming opinions already formed of older acquaintances. One of the fascinations of *Rose-growing* lies in adding to our collections each year some varieties of which we have had no previous experience, and there is no reason why the town gardener should deny himself this small luxury, however limited his domain, though experience will soon have taught him that he may not hope to succeed with all he plants.

But there are always a certain number of trees which should be discarded at the end of each season, and even if the grower finds he has added to their numbers, it is not all wasted effort, for he has added to the sum of his knowledge, and occasionally he will chance upon a discovery that will reward him for his pains. Last autumn I obtained a few plants of a charming little *Rose*, *Mevrou Dora von Tets*, choosing it merely from a catalogue description, and have been delighted with the result. Rather resembling *Richmond*, it is freer in growth, and even more profuse in blooming. In colour it is rather darker, being a full rich crimson, which lasts well even in bright sunshine. It is a thin *Rose*, and will hardly give a flower of exhibition size; but each one is of beautiful shape, and it makes an ideal bedding *Rose*. It is fragrant, and does not seem given to mildew, so that none need avoid it. The National *Rose Society's* official catalogue makes no mention of this *Rose*, and but few nurserymen in this country appear to have it in their lists; but in conversation with one the other day I learned that he had been much impressed by it and had budded a large quantity in anticipation of a big demand when its merits are better known.

Of *George Dickson* I write more reluctantly and with some diffidence, but must confess to some disappointment in finding it so easy a mark for mildew, and though there can be no question of its vigour, I suspect it a little of being inclined to the production of wood at the expense of flower.

A *Rose* that has proved its suitability for town gardens is *Mrs. Charles Curtis Harrison*, a bedding variety of carmine and crimson pink colouring, which does not fade into an ugly colour as many of similar shades do. This is one of the newer varieties which have been rather overlooked, probably because of the preponderance of pinks; but it is very distinct, and is a beautiful and shapely *Rose*, with stiff and well-formed petals, alike useful for garden or exhibition.

The free use of the hoe upon *Rose-beds* is to be commended at all times, but great care should be exercised in doing the work. Many roots are near the surface, and to break and injure these will cause a set-back to the plants. The hoe used should always be a narrow one, and only the top inch or 2 inches of soil ought to be disturbed. By the way, a most useful instrument can be made by fastening a light three-pronged garden hand-fork upon a broom handle, and with this the surface of the *Rose-beds* can be pricked over with a minimum of effort.

P. L. GODDARD.

HARDY HIMALAYAN PRIMULAS.

THE hardy species of *Primula*, so far as at present known, include about seventy varieties. A considerable number of these have been in cultivation for a good many years, and there can be little doubt that a large proportion of those which are not yet to be seen outside botanic gardens, or a few other collections of more than usual size, will be found hardy enough to stand the trials of our climate. Of those which are cultivated, a certain number are liable to rot off at the crowns during a wet winter, but they are generally hardy.

The fullest account of the *Primulas* of the Himalayas at present to be met with is that entitled "Observations on Indian *Primulas*," by Sir George Watt, C.I.E., M.B., C.M., LL.D., which was read before the Horticultural Club in 1904, and republished in the *Primula Conference Report* of the Royal Horticultural Society, 1913. This was supplemented at the conference by a paper by Mr. W. G. Craib, M.A., entitled "Notes on Himalayan *Primulas*," and also published in the *Conference Report*. This is a review of the work done since the appearance of Sir George Watt's contributions. These papers, with the monograph by Pax in Engler's "Pflanzenreich," contain practically all our knowledge of these *Primulas* from a botanist's point of view. It is my object to discuss them from a horticultural standpoint.

***P. bellidifolia* (King).**—This belongs to Pax's section *Capitatae*; it is closely related to *P. farinosa*, and, as Sir George Watt well remarks, may be considered a large condition of *P. farinosa*, our Bird's-eye Primrose. It comes from Sikkim, where it grows at an altitude of 13,000 feet. It has good-sized heads of many bluish purple flowers. It conforms to the same treatment as *P. farinosa*.

***P. capitata* (Hook. f.).**—One meets with many who fail to discriminate between *P. capitata* and *P. denticulata*, but those who have seen the two together will at once recognise their great distinctness. *P. capitata* is easily recognised by the dark blue colour of the narrow, bell-shaped flowers in a close head, the outer blooms being pendent; but an unfailing means of differentiating between *P. capitata* and *P. denticulata* lies in the fact that in the former the scape rises with the leaves, and does not precede them, as is the case with *P. denticulata*. This is mentioned because some of the colours now seen in the varieties of the popular *P. denticulata* closely approach those of *P. capitata*. *P. capitata* is a handsome species, a foot or more in height. Sir George Watt considered this possibly only an alpine form of *P. denticulata*. The leaves are frequently farinose, but the forms without meal are the hardiest. In cultivation *P. capitata* is usually only a biennial, but in some places it is perennial, and in others it flowers and sows itself quite freely. There is an interesting double-flowered form of this variable species.

***P. denticulata* (Smith).**—It is almost unnecessary to say much regarding this well-known and favourite species. It is one of the easiest to grow, but resents drought, and suffers greatly in dry positions during hot weather. It is the most abundant of the Himalayan *Primulas* in a state

of Nature, and extends over a large portion of the Himalayan regions, where it is generally found on grassy hillsides. It varies greatly in size, and in cultivation it is most variable in colour. We now have many varieties, not only of *P. denticulata* type, but also of the form *cashmeriana*, which is mainly distinguished by the beautiful farina on the under surface of the leaves. There are many forms passing under various names, such as *alba*, *major*, *minima*, *maxima* and others, while the colours range from white through shades of purple and lilac and rose. It is quite hardy, but sometimes suffers in variable winters by water lodging in the crowns.

***P. elongata* (Watt).**—A *Primula* which is nearly allied to the well-known *P. sikkimensis*, but still more nearly to *P. obtusifolia*, is *P. elongata* from Sikkim, where it grows at heights of from 11,000 feet to 12,000 feet. The flowers are yellow and very delicate, with petals which are thin,

leaves, and also by it having the flowers on short but distinct pedicels, while those of *denticulata* are sessile or nearly so. This may be considered a geographical form of *P. denticulata*. It comes from Kumaon and Bhutan, but is not found in Sikkim. The flowers are of much the same colour as in *P. denticulata*. When first shown in London, *P. erosa* was described as having larger flowers, but this is not the case.

Morelands, Duns.

JOHN MACWATT.

(To be continued.)

LEWISIA HOWELLII AS A MORaine PLANT.

THE illustration of this interesting plant was taken in the nursery of Messrs. Wallace and Co., Colchester, in the early days of June. This plant, which is growing in a moraine, is of exceptional interest by reason of its free-flowering propensities.

LEWISIA HOWELLII GROWING IN A MORaine. THIS PLANT PRODUCED OVER FOUR HUNDRED FLOWERS THIS YEAR.

smooth and veined. It has the smooth leaves of *P. sikkimensis*, but the corolla tubes are much elongated. *P. elongata* is not difficult to cultivate under the same conditions as *P. sikkimensis*.

***P. Elwesiana* (King).**—Handsome though this is, it is not so easy to cultivate as many of the Himalayan species. *P. Elwesiana* comes from Sikkim, where it grows at a height of about twelve thousand feet. It is worthy of any amount of attention from those who are fortunate enough to possess it. It is rather pubescent, although the leaves are coriaceous, and has large, solitary flowers of purple or violet. It belongs to Pax's section *Omphalogramma*, and is nearly related to the charming *P. vincaeflora*.

***P. erosa* (Wall.).**—Pax places this among the *Capitatae*, and it is very closely related to the popular *P. denticulata*. It is distinguished from the latter by its very large and thin erose

leaves, and also by it having the flowers on short but distinct pedicels, while those of *denticulata* are sessile or nearly so. This may be considered a geographical form of *P. denticulata*. It comes from Kumaon and Bhutan, but is not found in Sikkim. The flowers are of much the same colour as in *P. denticulata*. When first shown in London, *P. erosa* was described as having larger flowers, but this is not the case. It has ten branched flower-spikes, each with from thirty to sixty buds and expanded flowers. The illustration scarcely does justice to this wonderful specimen, which carried over four hundred flowers this year. This plant has stood two winters, and is now better than ever. Its chief requirement appears to be thorough drainage, such as only a well-made moraine can give. As the *Lewisia* belongs to the same Natural Order as the *Portulaca*, otherwise known as Purslane or Sun Plant, it is, perhaps, not so surprising that it thrives when given perfect and thorough drainage and an open, sunny position. Unfortunately, a good many who would like to cultivate this charming and interesting plant find it very difficult to manage, especially when only given ordinary rock garden treatment. The success achieved in this instance may act as a guide to those who have tried the plant and failed.

THE DAFFODIL IN AUSTRALIA AND NEW ZEALAND.

I SUPPOSE there are some people who are observant by nature, and some who are not. I never do know the colour of Mrs. So-and-so's new gown, or what sort of hat Miss What-do-you-call-her wore at that garden-party. Until I had a house to furnish, I never seemed to realise any great difference between chairs and tables, but when the necessity arose I never saw any chairs or tables alike. History has repeated itself with me in the case of the Daffodil in Australia and New Zealand. I knew that there were people there who grew the flower. I even knew that people of the names of Thomas, Rhodes, Clark, Miller and Buckland had started the fascinating game of hybridising, and that they had turned out some good seedlings; for pictures now and again found their way to Whitewell, and I had seen a real New Zealand-raised bloom in one of Mr. A. M. Wilson's collections at Vincent Square last year. Further, I knew from what Miss Currey used to tell me years back, and from information given me by my old friend Kingsmill about the celebrated syndicates of the late nineties, that some of the very best of our home-raised varieties were going to those regions year after year. I knew that there were shows at such places as Melbourne and Auckland and Christchurch.

But I had no idea of the vast extent to which the cultivation of the Daffodil had spread, more especially in New Zealand; nor of the great army of seedling-raisers already at work; nor of the network of shows; nor of the large quantities of the better sorts that are yearly passing from us to them. All these things were a revelation, and, unless I had had to forage about for material for the 1914 Royal Horticultural Society's "Daffodil Year Book," in all human probability they would still have been unknown, and the writing of this present article no more possible than for me to chronicle the doings of the Martians in Mars. Let me deal, then, in orderly sequence with my subject, and, for the sake of clearness, let me divide it into "heads"—"Growers," "Seedling-Raisers," "Shows," and "Dealings."

Growers.—Casual words frequently reveal more than set phrases or sentences. The casual words here are the prominence given to the Daffodil in such papers as the *Farm Journal* of Sydney (August 1 and September 1, 1913); the *Weekly Press* of Christchurch; the *Otago Witness* of Dunedin (October 8, 1913); and the *Weekly Graphic* of Auckland (September 18, 1912). Illustrations in quantity and columns of space are not given by editors to anything and everything. When we do find them, they betoken a public who want them. These, of course, might not be growers. What, however, can be the meaning of a catalogue like that of Messrs. W. H. Higgins, Limited, of Geelong, Victoria, with thirty pages out of forty given up to Daffodils; or Reilly, Gill and Co.'s (Dunedin) list of 276 varieties, but that someone wants them for their garden? Why is it that little spring shows are rising up like mushrooms all over New Zealand, and that in them Daffodils are invariably the leading feature? Why does St. John's Church, Fielding

(Wellington), or St. Luke's, Rotorua (Auckland), or Palmerston North, or the Presbyterian Church of Cambridge (Auckland) have a Daffodil society or an exhibition where Daffodils are the flowers? Why? Because there are people in their midst who are growing them. A few large shows like those of Dunedin or Auckland or Christchurch need not indicate a wide interest. A multiplicity of small ones does so.

Seedling-Raisers.—I am unable to say very much about the seedling-raisers of Australia. To begin with, as far as I know, Daffodil cultivation is confined to New South Wales and Victoria; but why South Australia should not join in I cannot imagine. Perhaps it does and I do not know it. If so, there may be a seedling-raiser or two there. In the other provinces, as far as I have been able to ascertain, there are but five or six of any wide repute—Messrs. Leonard Buckland, Alister Clark and D. V. West in Victoria, and Messrs. H. Selkirk, H. H. B. Bradley and Arthur Yates in Sydney. Mr. Clark specially goes in for triandrus hybrids; Mr. Selkirk, in the warm climate of Sydney, finds Tazetta hybrids (tridymus and Poetaz) the most satisfactory; Mr. Bradley, the secretary of the New South Wales Horticultural Society, goes in more for all-round hybrids; Mr. Yates, ditto; Mr. L. Buckland has been very successful of late years, and has won the Boyce Cup for twelve seedlings at the Royal Horticultural Society of Victoria Show. In the Ballarat Show, in the forty-eight class he had about twenty-four of his own seedlings in his collection. Two of his very best are named Pink 'Un and King of the Poets. Mr. D. V. West has been hybridising for many years and has produced some fine flowers. A Leedsii of much the same proportions as White Emperor won the premier prize for a single bloom in that division at the last Ballarat Show; and his beautiful white Apex, Mrs. D. V. West, received, as long ago as 1911, a first-class certificate from the Victoria Daffodil Conference. He most kindly sent me two photographs of it, one of which is reproduced on this page. The other, together

with an English photograph of a Penzance-grown Mrs. D. V. West, are to appear in the Royal Horticultural Society's "Daffodil Year Book." By the way, now that I know exactly what will be in it, might I suggest that half-a-crown spent upon a copy will be half-a-crown well invested. It was published on August 1, and may be obtained, post free, from the Secretary, Royal Horticultural Society, Vincent Square, Westminster, for 2s. 9d.

I believe what Mr. West says of Victoria is likewise true in spirit of New South Wales hybridisers:

"I think there are only three who have been raising for over ten years, although *there are many more of recent years.*" We do not know what surprises may be in store when these new recruits have become veterans and given the public a sample of their wares. We do not even know all the quiet work that is going on in our own islands. I was surprised when, at one of the Royal Horticultural Society's shows this spring, my young friend, Mr. Guy Wilson of Knowhead, Broughshane, said, "I have got something to show you

of *Irish Gardening*, as his did this last June! But what of New Zealand? Recording his impressions in his celebrated tour of the world, the later Peter Barr is reported to have said in Melbourne (Victoria) that "the folks in New Zealand talked Daffodils morning, noon and night." Had he timed his visit for September, there is little doubt but that he would have seen, even then (1900), that they do more than talk. He would have seen fine collections staged and keen competition at the large shows; and had he visited

the homes of many, he would have seen larger or smaller quantities of seedlings of varying ages. In 1897, in the first year of the Dunedin Show, there was a class for New Zealand-raised seedlings, which was won by Mr. Thomas Cranwell. But the credit of being the first to flower a home-raised bloom belongs to Mr. Biggs, who in 1879 fertilised gloriosa (Tazetta) with breviflos, and as a result had two plants of the tridymus type, which, flowering first in 1886, still flourish in his garden.

Probably the best-known names in the two islands are those of Professor Thomas of Auckland and the late Mr. Mason of Wellington in the North; and of the Hon. R. Heaton Rhodes and Mr. A. E. Lowe of Otahuna, Christchurch, of Mr. H. Hart of Lawrence, and of Mr. Andrew Miller of Dunedin in the South. These, however, are by no means all. Just take some of the names that I am acquainted with: Messrs. Lennie, Grindrod, J. G. Davies (the first man to get an award—1899—for a New Zealand-raised flower), Wilson, Maclean, Haggitt, Findlay, Trevena, Gibson and Branthwaite. Then imagine the goodly number that I do not know, and you will be able to form some estimate of the extent to which this fascinating hobby is being taken up by those who dwell in "The Long White Cloud." JOSEPH JACOB.

(To be continued.)

MUEHLENBECKIA COMPLEXA AS A WALL PLANT.

WE are accustomed to see the slender, wiry stems and elegant leafage of this charming little trailer spreading prostrate over the boulders of a rockery, or sometimes hanging over the face of a retaining wall; but when visiting the Suffolk town of Wood-

bridge, some beautiful examples were seen treated as climbers, in front of houses by the roadside. Some of the plants thus growing must be of a great age, judging by the wall space covered and the thickness of the main branches or stems. The method of treatment is to nail the leading growths to the wall and let the shorter side shoots hang free. In the course of a season or two the plants assume considerable proportions, and present a delightful appearance quite distinct from any other climber.

HEATHER BELL.

NARCISSUS MRS. D. V. WEST, A BEAUTIFUL NEW VARIETY RAISED IN AUSTRALIA. IT HAS BEEN FLOWERED IN THIS COUNTRY.

in the annexe," and when we got there, unearthed from under the staging a narrow flower-box full of his own seedlings! Real beauties, too, some of them were. For a certain number of years now he has been a visitor at Birmingham and London, and I had fully realised his fondness for the Daffodil; but I had no idea that all the time he had been quietly working and crossing, and that suddenly he was going to burst out as a full-blown hybridiser and raiser of seedlings; for what else can I call anyone whose exploits fill a whole page

GARDENS OF TO-DAY.

SHENDISH, KING'S LANGLEY.

A LARGE and beautiful rosary makes an imposing feature in Mr. T. N. Longman's delightful gardens at Shendish, King's Langley, Herts, and it was our good fortune a few weeks ago to see the Roses in the height of their beauty. The rosary is of formal design and partly sheltered by a belt of coniferous trees, which, however, are far enough away not to exclude the sunshine so essential for the well-being of Roses. In the centre of this garden of Roses is a large circular bed of Caroline Testout in both bush and standard trees. This grand old Rose still holds its own as one of the best, if not *the* best, of all the bedding Roses. Only one colour is allowed in each bed, and Lady Battersea, General Macarthur, Mme. Ravary, Lyon, Hugh Dickson, Mrs. Kershaw and Dean Hole are foremost among the varieties occupying surrounding beds, each doing its utmost to outrival its neighbour in producing a wealth of ever-welcome blooms. There are other varieties, too, worthy of special note among the thousand Rose plants which make up this beautiful rosary, and among them we see Richmond, Mme. Leon Pain, La Tosca, Clara Watson, Warrior and Antoine Rivoire. Perhaps La Tosca and Warrior are two of the most profusely flowered. The latter, with its deep Mulberry red flower-buds,

is literally smothered in bloom, and both of them may be relied upon to flower freely, however unfavourable the season may be. One corner of this Rose garden is devoted to single Roses, all emanating from Ireland. Irish Elegance is unquestionably the best of the bunch; but Irish Brightness, Irish Glory, Irish Modesty and Irish Harmony each gives a glowing account of itself, and all of them are much sought for in the decoration of tables. Grass paths separate the Rose-beds, and each bed is fringed with some free-flowering Viola of blue or mauve shade, the varieties most in evidence being Royal Blue, Mrs.

Chichester, Maggie Mott, Mauve Queen, Magpie and Kitty Bell. On the outside of the Rose garden, Roses of more or less rambling habit, like Penzance Briars, Sweet Briars, Grüss an Teplitz and Thermidor (the last named a white Rambler that flowers with great freedom), lend pleasing touches of colour that link up with the pleasure grounds beyond. A little Dutch garden situated quite close to the house is likewise well provided with Roses. Here the Dwarf Polyanthas Mme. N. Lévavasseur and Maman Lévavasseur, otherwise known as Baby Crimson Rambler and Baby Dorothy Perkins, are used with telling effect.

On another side of the house we observe beds of China Roses even more heavily laden with bloom than the bedding Roses already referred to. The two China Roses that appear to be doing the best of all are Fabvier (scarlet, white centre, and borne on stiff stems) and Mme. Eugène Résal, with a brilliant rose yellow base to the petals which is very effective.

A Delphinium Border.—One of the most delightful features of these gardens at the present time is a long and imposing border of stately Delphiniums. Mr. G. Burrows, the genial head-gardener, whose whole interest is wrapped up in the beautifying of these gardens, has for some years made a point of selecting his own Delphiniums from seed and raising a number of plants each year, with the result that he now has a unique collection of unnamed varieties under his care. Pale blue varieties seem to predominate, although deep purple and reddish purple shades are well represented. Mr. Burrows' method of culture is briefly as follows: Seed is sown at the end of July in boxes and placed in frames. In the spring the seedlings are planted out in a border, with the result that they flower in the following

A VIEW IN THE ROSE GARDEN AT SHENDISH. VIOLAS ARE SUCCESSFULLY USED AS EDGINGS TO THE ROSE BEDS.

BROAD STONE STEPS LEADING FROM THE ROCK GARDEN.

September. The best varieties are then selected and planted in their permanent positions in the border, where they may be expected to flower at their very best in the third year. In the spring the growths on established plants are thinned to five or six to avoid overcrowding. The border is edged with *Nepeta Mussinii*, an extraordinary floriferous plant, making dense, prostrate tufts with numerous spikes of little lavender flowers. This valuable subject is extensively used at Shendish as an edging to the flower borders. In addition to the *Delphiniums*, there is another blue border devoted to *Veronica spicata*, the plants being so well grown that they were not at first recognised. This border is also edged with *Nepeta Mussinii*, the free-flowering Catmint, making a charming study in blue.

Rock and Water Garden.—The rock garden, situated on the site of an old chalk pit, is built on a slope facing west, and beyond is a beautiful glade and a dell or wild garden where *Rosa Brunonii* (a synonym of *R. moschata*), a climber with yellowish white flowers, is naturalised, with most pleasing effect. *Geranium Endressii*, a Pyrenean species with pale rosy flowers, is also naturalised in the dell, where it is associated with hardy Ferns. Millstone grit and Derbyshire limestone have both been used in the making of the rock garden. Stepping-stones are placed here and there in grass paths, and these are quite in keeping with the stone steps, which, by the by, are furnished with low-growing alpines, such as *Campanula pulla*, *C. pusilla* in variety, *Arenaria*, *Erinus alpinus*, *Thymus Serpyllum*, *Dianthus cæsius* and *Sedums* in variety. A wealth of colour was created by *Campanula muralis*, Rock Roses and innumerable varieties of alpine Pinks and Phloxes at the time of our visit. The shrubby *Ozothamnus rosmarinifolius* is used to good effect in the background, its pleasing white flowers resembling those of a shrubby *Spiræa*. *Viola gracilis* is also very showy, while the patches of *Gentiana verna* and *G. acaulis* tell of the superb effect made earlier in the season.

The water garden, backed by stately Oaks and situated on a slope to the west, is happily conceived and planted with good taste. The Japanese Iris *Kämpferi* is grown with marked success, and the same may be said of the Siberian Flag, or *Iris sibirica*. English and Spanish Irises also flower well, but with the latter it is found necessary to plant annually. The Goat's-beard (*Spiræa Aruncus*) and the Royal Fern (*Osmunda regalis*) make noble pictures on the banks.

A notable feature of the gardens at Shendish is seen in the magnificent sweep of lawn, including one of the finest bowling greens in the county. The house and gardens are situated at the top of a prominent hill 480 feet above sea-level. At the foot of the hill nestles a pretty little village with its own church and village green, and the model cottages are the homes of farm and garden hands on the Shendish estate.

MAKING NEW STRAWBERRY-BEDS.

WITH the coming of August the time for preparing new Strawberry-beds arrives. There is perhaps no fruit more easily grown or one which so gratefully repays a little extra care in cultivation. Its shallow-rooting nature renders it particularly liable to suffer from drought, and the preparation of the soil must therefore be carried out with this fact in mind. If the ground can

tended, a small crop may be expected the following year. The advantages of planting the small pot plants offered by nurserymen are many, and for those to whom time is a consideration they amply justify the extra cost. It is always the earliest runners (and therefore the strongest) that are laid into pots, and, furthermore, the roots suffer little or no disturbance on replanting.

In the matter of soil, the Strawberry is most accommodating. It may be found in the heaviest clay and in the lightest sands. Naturally, a rich loam is most suitable; but, failing this, much can be done in improving dry soils as before described and in lightening heavy soils by lime or mortar rubbish, always remembering that the most important point is the water supply. The distances for planting vary much, some preferring to plant 3 feet apart in the row and between the row, others making two rows at 2 feet apart and having a wider space for a path between every two rows. Where several varieties are grown together, it is a convenience to make the rows run the shortest way of the bed, so that each variety is in small blocks rather than long lines.

The plants, when safely through the danger of drought, should need no further attention until the spring, except in so far as a supplemental supply of manure is concerned. A liberal use of stable manure, with an addition of wood-ashes to supply the necessary potash, will provide all that is necessary. If, however, manure is not available, spent Hops, leaf-mould or rape dust should be given with 1 lb. of sulphate of potash for each 40 square yards in the winter, and in the spring 8 lb. of superphosphate and 2 lb. of sulphate of ammonia for the same area. Having briefly dealt with cultural matters, it remains to suggest a few varieties which will give a good succession of fruit.

The earliest fruit in most gardens is *Vicomtesse H. de Thury*, which, unlike most early fruits, possesses an excellent flavour. For the second earliest variety *Royal Sovereign* still stands unbeaten, and *Presi-*

dent is quite one of the best varieties for the main crop. It has some of the old "pine" flavour. A little later on there comes *The Bedford*, a new-comer which has made its way to the front, as it possesses good size, first-class flavour, and is a constant bearer. In season it will follow the first two named. Of the later sorts *Givon's Late Prolific* is quite the finest. The vigorous foliage keeps the plant in good health, and the crop is produced over a very long season. This list would provide a good selection for gardens of medium size, and are of varieties which can be relied on without any very special cultural attention. For those who regard flavour of much more consequence than production of fruit and vigorous growth, *British Queen* and *Dr. Hogg* cannot be omitted. Among the newer

A WATER GARDEN SCENE IN THE GARDENS AT SHENDISH, KING'S LANGLEY.

therefore be trenched 2 feet deep and well-rotted manure incorporated in the soil, this will aid greatly in conserving the moisture. In these days of motor-cars it is well perhaps to add that, failing stable manure, leaf-mould or spent Hops will serve the same purpose, but these will need to be supplemented with chemical manures.

Any garden which has been well cultivated and manured for vegetable crops will not need this special attention, and in this case the manure will be better added at a later period. The great advantage of August planting is that the young runners may make good growth before the winter, and therefore no care should be spared to keep them well watered should a dry time follow their planting. From good runners thus

sorts Hibberd's George V. is one of remarkable promise, coming about two weeks later than Sir Joseph Paxton, and produces a large number of fine scarlet fruits of firm flesh and excellent flavour. This is without doubt a variety of the future, and before long will be found in all gardens.

I cannot conclude without recommending once again the valuable service rendered by the autumnal Strawberries, of which so many have been produced within recent years. The two varieties which have shown the greatest promise are the Merveille de France and St. Fiacre autumnals. Both of these may be relied on to give a crop of fruit of first-class flavour from the middle of August till September, and in sheltered positions even later. A corner should be found for these in every garden, as they

We generally sow the seed the last week in August, and pot off the resultant seedlings as soon as possible in 2½-inch pots, placing them in a light position, yet not in the direct rays of the sun. A frame outdoors having a northern aspect is excellent. As soon as growth has become active, pinch out the growing point and repeat it later, but the second time pinch all the laterals as well. This will lay the foundation of a strong, well-branched plant. Before the plants get root-bound in the pots (and this must never be allowed to occur, as the plants may as well be thrown out as allowed to flower), a further move into 5-inch or 6-inch pots must be given. The 5-inch pots are perhaps the best, as it is not wise to over-pot them. They are impatient of careless watering and drought, either extreme proving fatal to one's hopes. Steadily keep to the pinching and repotting,

they may be top-dressed with the same mixture as advised for the final potting. They may then be given a little diluted cow-manure, gradually increasing the strength of it until the flowers look ready for opening, when it is best to cease. They may then be moved to the conservatory.

CHARLES TROTT.

Ewood Hall Gardens, Mytholmroyd, Yorkshire.

NEW AND RARE PLANTS.

Petunia Purple King.—A very handsome double-flowered variety, colour imperial purple, of a rich intense shade. Very striking and distinct. From Mr. A. E. Billingham, Broadway, Croydon.

Erica vagans St. Keverne.—A very charming bright rose pink flowered variety of a beautiful plant. When sufficiently plentiful it will be sure of a warm welcome. Shown by Mr. P. D. Williams, Lanarth, St. Keverne, Cornwall.

Carnation Mrs. F. G. Bealing.—A salmon pink coloured border variety, showing considerable freedom of flowering. From Mr. F. G. Bealing, Bassett, Southampton.

Lælio-Cattleya Miss Louisa Fowler (Lælio-Cattleya callistoglossa × Cattleya granulæa).—Sepals and petals mauve, lip rich purple. A very beautiful variety. From Mr. J. Gurney Fowler, Pembury, Kent.

Cattleya hardyana rubens.—Large purple lip, with rosy mauve sepals and petals. From Mr. J. Gurney Fowler.

Oncidium Leopoldii Fairlawn Variety.—The predominating colour is mauve, shaded with green, the inflorescence bearing a considerable number of flowers. Shown by Mr. H. Goodson, Fairlawn, Putney.

Cattleya Astron (Cattleya Dusseldorfi variety Undine × C. Harrisoni alba).—A very charming white form, the widely winged sepals and petals and lip slightly touched with yellow in the throat, making up a really beautiful flower. Shown by Baron Bruno Schröder, Englefield Green.

The foregoing were shown before the Royal Horticultural Society on the 28th ult., and each received an award of merit.

Gladiolus Loveliness.—A delightful mingling of pale pink and cream, with yellow shading, in a flower of fine texture and splendid proportions. Some grand spikes were shown. First-class certificate.

Gladiolus Fire King.—A magnificent variety of flame scarlet colour. The spike is very fine.

Gladiolus Armagnac.—This splendid variety is coloured crimson, with a conspicuous white throat.

Gladiolus Chicago White.—A handsome white variety, with rosy markings in the throat.

Gladiolus Marie Therese.—A nearly pure white variety of handsome proportions, marked with rose on a straw-coloured blotch. The foregoing five varieties were exhibited by Messrs. Atkinson and Statter, Locksheath, near Southampton.

Gladiolus Abeliard.—A handsome spike of soft pink flowers, lightly striped a deeper shade of the same colour.

Gladiolus White Giant.—The spikes were of splendid proportions, the handsome, pure white flowers well meriting the description of "Giant." It is one of the finest we remember to have seen. These two were exhibited by Messrs. Kelway and Son, Langport, Somerset.

Each of these Gladioli received an award of merit from the National Gladiolus Society on the 28th ult.

A SCHIZANTHUS PLANT GROWN FROM SEED AS DESCRIBED ON THIS PAGE.

provide a welcome addition to the fruits of the holiday season.

E. A. BUNYARD.

SCHIZANTHUS AS A SPRING-FLOWERING PLANT.

THE value of Schizanthus as a spring-flowering plant cannot be over-estimated, and a good batch of this popular yet dainty and light flower is more appreciated at that season of the year than at any other time. Not only do the plants flower more profusely, but the absence of that scorching sun which is experienced later on in the year allows them to retain their beauty and freshness for a considerable period. A conservatory in which the main subjects are Primulas of sorts, herbaceous Calceolarias and Schizanthus wisetonensis is a sight to remember.

never hastening the plants in any way, and by the middle of October they may be potted into the final or flowering pots. These may be either 8 inches or 9 inches in diameter, according to the grower's discretion or convenience. The soil for this potting is very important, and should not contain too much humus and no artificial manure, unless it is a little bone-meal. Good strong loam should comprise three parts of the mixture, the other part consisting of wood-ashes, lime rubble and leaf-mould. Firmly press the soil around the plants as the work proceeds, and leave quite 3 inches for top-dressing if in a 9-inch pot, and a little less if in an 8-inch pot.

Stake the plants nicely, and if the weather is still open they may be left in the frame. I have known them to experience 5° or 6° of frost and take not the slightest harm. However, it is always the best plan when they have got so far on to take no chances; but never give them more heat than is absolutely necessary to be safe. As soon as they start growing again,

GARDENING FOR BEGINNERS.

HOW TO FORCE FREESIAS, HYACINTHS AND NARCISSI.

THE amateur cultivator, especially the beginner, derives a great deal of pleasure from the work of forcing bulbs in pots. Many bulbs are confined to a small space, and as every stage of growth is watched by the cultivator, the latter becomes deeply interested

DIAGRAM SHOWING THE RIGHT AND WRONG METHODS OF POTTING FREESIAS.

in the welfare of the plants and likes to learn how he can improve them from year to year. Now, all this is very interesting if the bulbs grown are good ones. If they are unripe, small, soft and do not contain an embryo flower-stem or only a very weakly one, then the efforts of the cultivator, however well they may be directed, will not be of much avail. The best bulbs are not always the largest; the finest are those which are very firm and thoroughly matured. When selecting the bulbs, therefore, the cultivator should be sure that they are heavy for their size and quite firm near the crown.

Composts for Pot Bulbs.—In every case a fairly light compost is the most suitable, and porosity of the soil is very essential to success. Old loam is better than new, so that the cultivator should give preference to the former. If there is only a small quantity of old loam available, then some old potting soil—that which has not been in pots long enough to become sour—should be mixed with the portion of new loam to be used. Leaf-soil is a valuable ingredient. It may be used at the rate of one-third of leaf-soil to two-thirds of loam, and sand sufficient to ensure the sound drainage of all soil placed in the pots. If manure is added, it must be well decayed and slightly dried in an open shed, then rubbed through an inch-mesh sieve. Artificial manures must not be added, as all necessary feeding can be done after the pots are taken from the plunging material.

Freesias.—There must be a careful grading of all Freesia bulbs before any are potted. If the small ones are potted indiscriminately with the large, then there will be fewer blooms in each pot, and the small bulbs will not improve much in size. No. 1 in Fig. A shows the smallest bulb. Such must be potted separately, as few of them will produce flower-stems. No. 2 bulbs must also be potted separately. A number of them will bear flowers, and these will be useful for cutting to place in vases. No. 3, the largest bulbs, should be potted separately. These will produce the finest flowers and look remarkably well in the

greenhouse or conservatory. In every case the bulbs should be put in about an inch apart, whether large or small or medium, and then all have freedom to grow and develop fully during the season. Having well drained the pots—which may vary in size from 3½ inches to 6½ inches—put in a small portion of rough compost, then some finer, and, having slightly firmed it, place the bulbs as shown at No. 4, burying them in the proportion depicted. It is wrong to pot them as shown at No. 5. When potted, give water freely through a fine-rosed watering can and plunge the pots in sand, old ashes or common soil as shown at No. 6, not covering the surface of the soil and the rims of the pots. They may be arranged in a dry place in the open air, or in a cold frame from which the glass lights must be removed in dry weather until the leaves appear through the soil.

Roman Hyacinths.—No. 1, Fig. B, shows a Roman Hyacinth bulb. Five good bulbs may be grown in a 6½-inch flower-pot and four in a 5-inch one. No. 2 shows the correct way to pot these bulbs. Having loosely filled the pot level with the rim with the prepared compost, scatter some sand on the surface and then press the bulbs down as shown in the sketch. Add any more compost as may be found necessary to

HOW TO POT ROMAN HYACINTHS FOR FORCING.

complete the potting. Another way is to three parts fill the pots with compost and make it firm; then put in the bulbs and surround them with soil, leaving, as shown, the crowns of the bulbs above the surface. Water the soil freely; then put empty inverted and smaller pots on as shown at No. 3. Cover all with old ashes or sand until the new growth is nearly two inches high.

Narcissi.—No. 1, Fig. C, shows a Narcissus bulb, and No. 2 the correct way to pot them. The new growth of well-buried bulbs is always stronger than that of those so buried as to leave the crowns above the soil; but if the bulbs are very large and many flowers are required in each pot, then, in order to get in more bulbs, the latter may be potted higher up at the widest part of the pot, so as to leave the crowns of the bulbs just visible. Water these bulbs, too, and then bury them under the ashes, as shown at No. 3, in any position outside if the base is well drained.

When New Growth Begins.—When the new shoots have commenced to grow freely, the pots

must be removed from the covering material and placed in a cold frame, there to remain for several weeks. The frame must be covered with mats for at least a week, and then full light should be gradually admitted. The same course must be adopted in regard to the ventilating of the frame; little at first, then abundance. From the frame the pots can be taken to the greenhouse or other structure in which a warmer temperature can be maintained, and flowers obtained to form a succession in due time.

G. G.

THE CULTIVATION OF ENDIVE.

VERY few cultivators grow fine plants of Endive. If matured where sown, the plants must be thinned early and freely, as overcrowded plants never give satisfaction. When transplanted, the Endive must be grown in rich but firm soil. If a succession of plants is required over a long period, the following treatment will prove helpful: At least two sowings should be made, one early in July and another early in August. The plants resulting from the latter sowing of seeds will be useful for lifting and replanting in a frame. If possible, avoid growing Endive on any ground recently occupied by Cabbages or Cauliflowers, as the latter crops impoverish the soil too much for the Endive to do well. Ground from which Peas, Beans or Turnips have been cleared will be quite suitable. Dig up such soil, put in a liberal quantity of well-rotted manure, break up all large lumps, and tread down the soil again while in a fairly dry state; then put out the young Endive plants 18 inches apart each way and water them. The plants spread considerably, and when fully grown will almost cover the whole space. Planted nearer than stated would cause inconvenience, as the workman could not get between the plants to attend to them. All early plants may be blanched by gathering up the outside leaves at midday, when every leaf is quite dry, and loosely tying them in the same way as Lettuces are tied. The later plants should be carefully lifted and replanted in October in a cold frame rather close together and in raised soil. The outside leaves will gradually decay. As they do so, remove them. Ventilate very freely in fine weather, and so guard against excessive moisture; then a nice supply of fresh and well-blanch hearts may be secured.

SHAMROCK.

THIS DIAGRAM ILLUSTRATES THE POTTING OF DAFFODIL BULBS FOR FORCING.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Early Muscat Vines from which the crop has been gathered should receive careful attention with regard to insect life. If red spider or thrip is present on the foliage, some means must be adopted to rid the Vines of these destructive pests, or the prospect of a satisfactory crop next season will be much reduced. If the borders are well drained and the roots healthy, liberal supplies of clear, soft water should be given, and the foliage syringed daily with a view to keeping it quite free from insects.

Late Muscat Grapes will require moderate heat in the pipes at night to ensure a buoyant atmosphere, if the berries are to be quite ripe and well coloured by the end of September. While the berries are swelling, there must be no lack of moisture at the roots; and when water is necessary, a bright day should be chosen for applying it, so that the ventilators may be open during the day and partly so at night. Do not allow the growths to become overcrowded, but, at the same time, sufficient young shoots must be retained to keep the roots constantly active. A night temperature of 75° should be maintained.

Pot Strawberries.—The early batch of plants should be potted with as little delay as possible. The soil may consist of three parts turfy loam and the remainder of decayed manure, and this should be thoroughly mixed a few days previous to use. Make the soil firm about the roots, but do not break the small balls of soil in which the young plants have been growing.

Plants Under Glass.

Zonal Pelargoniums.—Plants for winter flowering should now be established in 6-inch or 7-inch pots, and must be grown in the open quarters fully exposed to the sun, and secured against rough wind. Keep the plants within bounds by pinching leading shoots as it becomes necessary. No great quantity of manure need be applied at present, but soot-water may be given about once weekly to keep the foliage in a healthy condition.

Crotons.—Well-coloured tops may still be inserted in the propagating frame with a view to raising young plants for decoration during the winter. These are very useful for small groups, for filling large vases, or for table decoration. When sufficiently rooted they may be potted into 4-inch pots and grown in an exposed position in the stove in order to increase their colour.

Pot Roses which are growing in the open must not be neglected, but should receive daily attention to watering and cleaning the pots. Give frequent applications of soot-water or liquid manure from the farmyard.

Humea elegans.—Young plants should now be potted into 4-inch pots and placed in a cold frame. Water carefully until they become established, and open the ventilators early each morning, but avoid draughts.

The Flower Garden.

Pansies.—The seedlings should now be ready for transplanting in a well-prepared border, and may afterwards be transferred to their flowering quarters. Keep the young plants well supplied with moisture at the roots, and stir the soil frequently with a Dutch hoe.

Belladonna Lilies growing under a south wall should be given a good soaking of clear water, and the soil lightly stirred with the point of a small fork. This will give vigour to the plants and enable them to push up their flower-spikes.

Hollyhocks.—To obtain the best results with these, the seeds should be sown now in pans of sandy soil and placed in a cool, shady pit until germination takes place. Prick out the young plants as soon as large enough to handle, and ultimately pot into 5-inch pots and grow as hardily as possible. By this means good strong plants should be available in the beginning of April.

The Rock Garden.

Taking Cuttings.—August is the best month for taking cuttings of Phlox, Dianthus and numerous plants for the rock garden. The best

method is to insert the cuttings in small pots or in pans of sandy soil, and place them in a close, cold frame facing north.

Shrubs Suitable for Rock Gardens which may be propagated during the autumn should include *Hypericum olympicum*, *H. patulum*, *H. Nummularium*, *Cistus* in variety (these require a warm, dry soil, with a certain amount of shelter), *Olearia stellulata*, *O. Haastii*, *Cotoneaster humifusa*, *Daphne Cneorum*, *D. blagayana*, *Genista tinctoria*, *G. anglica* and *G. sagittalis*.

The Kitchen Garden.

Cucumbers.—If winter Cucumbers are desired, there must be no delay in sowing the seeds, which should be placed in small, clean pots over a gentle hot-bed until germination takes place, after which the pots may be raised to within 1 foot of the roof glass, in order to keep them stocky. When they have made a leaf or two they may be potted into 5-inch pots, and should be ready for planting about the third week in August. Another sowing may be made a month later for fruiting in the new year, during the first three months of which Cucumbers are sometimes difficult to grow in consequence of dull weather.

Late Peas.—The latest batch of Peas should now be growing freely, and, if dry weather continues, they will require a good supply of water at the roots. A mulching of farmyard manure should also be applied.

Carrots.—It is not too late to make a sowing of stump-rooted Carrots for use during the winter, or for leaving in the ground until the spring. Young Carrots which are just showing through the surface should be thinned as soon as possible, the ground broken between the rows, and a light dusting of soot given.

Onions.—A sowing of Golden Rocca and Ailsa Craig should be made about the middle of August. The bed must be deeply dug, but no fresh manure applied. When the soil has become dry, the bed may be trodden evenly and raked level. The drills should be at least 15 inches apart. A dressing of soot may be given with advantage previous to digging the ground.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cauliflowers.—There is usually a superabundant supply at this season, and it will be wise to go over the plot frequently and bend over a few leaves to protect the heads from the sun's rays. Later plants will be greatly benefited by a liberal application of liquid manure. Should this not be available, nitrate of soda will be a good substitute, an ounce to a gallon of water. Nitrate of soda is particularly distasteful to grubs.

Tomatoes.—A sowing may be made now to produce a crop of fruit in the winter, and as these plants have to pass through the dullest time of the year, they must be grown as sturdily as possible. Sow the seed thinly in pans, or, if only a few plants are grown, it would be as well to sow one or two seeds in small pots, leaving only the strongest seedlings. As soon as they have come through, place them on a shelf close to the roof glass, shifting them later into 6-inch pots.

Cucumbers.—To have a supply during the winter months, sow a few seeds in pots now, and make another sowing in about a month's time. Place them in the propagating-case, and if a suitable house is not ready for them, they will require to be potted on. Great care must be taken with this batch, as during cold autumn days mildew very often makes its appearance.

Lettuces.—A small sowing of some of the winter Lettuce can now be made, but only the hardiest sorts, such as Stanstead Park, should be grown. Make another sowing towards the end of the month, which in most cases ought to meet the demand.

The Flower Garden.

Bedding Geraniums.—A start must now be made to get a supply of cuttings for next year's requirements. As the season's display is by no means over, great care must be taken

not to disfigure the plants. Secure a number of each variety now, going over the plants again in about ten days' time, and if carefully done, these cuttings will scarcely be missed.

Heucheras.—Like the foregoing, these graceful perennials are easily increased by cuttings. As soon as the flowers are over, cut down the spike and secure a batch of cuttings, which will root readily in a cold frame. It is a good plan to plant out a number on a side border for cutting, as nothing is more graceful when arranged in vases. *H. brizoides* and *H. gracillima* are possibly the best varieties for this purpose.

Rock Garden.—As the season advances, this interesting part of the flower garden will require almost daily attention in the way of cutting off faded flowers and watering such as seem to be suffering. The cutting away of the faded flowers of Saxifrages gives them a new lease of life.

Plants Under Glass.

Lachenalias.—These useful greenhouse plants should now receive attention. Shake the corms from the old soil and pot them up in a mixture of loam, leaf-soil and sand. But perhaps the most effective way in which to grow them is in wire baskets suspended from the roof. For a time after potting keep the plants perfectly cool, and careful watering will be required until growth commences. No artificial feeding should be given until the flower-spikes appear.

Chrysanthemums.—As the pots are now becoming filled with roots, the plants must be regularly fed with one or other of the many manures now on the market. At the same time liquid manure from the farmyard and soot-water must not be despised. The taking of the bud of the single-stemmed varieties is a most important operation, and had better be left to the man in charge. In an ordinary way a start may be made now by taking them as they appear.

Marguerite Mrs. F. Sanders.—Cuttings of this useful greenhouse plant should now be secured for supplying flowering plants for the early summer. They will root best in a warm pit where they can be shaded for a time, after which they must be grown on in a cool, airy house. Pinch out the centres when they have made 4 inches or 5 inches of growth, to ensure a bushy habit.

Mignonette.—To have a batch of this fragrant plant in bloom in the winter and early spring, the seed must be sown without delay. To save disappointment it will be as well to sow three or four seeds in a small pot and retain the strongest seedling. Keep them in a cold frame well exposed to the light, and nip out the blooms as they appear until the plants are large enough.

Preparing Frames and Pits for Cuttings.—As the season is now at hand when a start must be made for securing cuttings that require protection, the pits and frames should be got ready for the various occupants. Very often cuttings are put into frames where the soil has possibly not been renewed for years. This is a great mistake, as it will well repay to renew the soil. Have the lights and glass thoroughly washed on both sides.

The Hardy Fruit Garden.

Raspberries.—Most of the fruit will now have been gathered, and, if time permits, have the old canes cut out at once, and leave only sufficient of the young ones to provide next year's supply. These had better be tied up loosely in the meantime to enable the canes to be thoroughly hardened. They would also be benefited by having the old mulching taken off and replaced with some fresh manure from the farmyard.

Plums.—These seem to be badly infested with aphides this season, and although there have been several heavy thunderstorms, they have failed to completely dislodge them. In such cases it will be well to have badly infested trees syringed with Quassia extract, and afterwards with clear water.

Cherries.—The fruit will now have been picked, at least of the sweet varieties, and the trees should receive attention. Lay in any shoots required for furnishing the wall, and if the soil is at all dry, give a good soaking of water to the roots. Perhaps Cherries suffer more from lack of moisture at the roots than almost any other wall tree.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

FRAGRANCE IN ROSES.

IN his interesting article on "Rose-growing in Town Gardens," page 329, issue June 27, Mr. Goddard challenges criticism when he writes that the pleasure derived from the sight of a beautiful Rose is "intellectual," while that given by the scent of a Rose is "purely sensual." Is memory purely sensual? Surely not. Surely it is memory that gives us our individuality, and few will deny that a waft of fragrance will recall the past more vividly than any vision can do. Smell, as Mr. E. F. Benson has well said, is the most "memoristic" of the senses; it certainly is the most emotional, and I should be sorry to think that intellect and emotion are necessarily antagonistic. Poetry has been described as intellect touched by emotion, and if I might borrow an idea from this phrase, I should say that a beautiful Rose without scent stands in the same relation to one with the added charm of fragrance that prose does to poetry. Like poetry, the fragrance of a flower may waken in us something that is far indeed from being purely sensual.

There is really no reason to depreciate one sense in favour of another; indeed, the senses are so closely allied that it is almost impossible to dissociate them from one another. If we see a lovely La France or Horace Vernet Rose, we unconsciously associate it with the delicious fragrance we know that it possesses; and so the mere sight of a flower we know to be fragrant gives us greater pleasure than the scentless perfection of a Baroness Rothschild or a Frau Karl Druschki can do. In saying this I do not suggest that we should never grow a Rose that is without scent. Some Roses—*Rosa sinica* Anemone, for instance—are so pleasing to the eye that we cannot forego the pleasure they give one of our senses merely because they do not gratify another; but I would plead for the inclusion in our gardens of such Roses as The Tuscan, Maiden's Blush and the old Damask, which, though lacking in size and form, are richly endowed with fragrance.

It is not necessary always to look back to past times for a sweet-scented Rose; many are still being produced. Evangeline, a single wichuraiana with the pink of the wild Rose, brought out in 1906, is delightfully fragrant, and in common with Grüss an Zabern, a snow white multiflora, has the power of scenting the air around it. In fact, the wichuraianas as a class are much more fragrant than were the old Ayrshires. They have got a bad name in this respect because two of the most popular, Dorothy Perkins and Hiawatha, are practically scentless; but François Juranville, coppery pink, and Paul Transon, a rampant grower, both have a most refreshing scent of Apples; the bright crimson Excelsa has also the fruity type of smell, and the large-flowered pale pink Gerbe Rose, besides having beautiful thornless green shoots and glorious foliage, is one of the sweetest of all Roses. The graceful pale pink Débutante and the new perpetual pure white Sylvia are well worth growing on account of their fragrance.

No doubt many of the lovely Hybrid Teas are not nearly so sweet as were the old summer Roses, such as Maiden's Blush and the Cabbage Rose, nor have they the deliciously refreshing fragrance of such Hybrid Perpetuals as Victor Hugo, Horace Vernet and many another veteran; but those rosarians who are on the look-out for fragrance, who also want the bright colour, pointed form

and perpetual habit of the Hybrid Teas, can find these qualities combined in Richmond, Liberty, André Gamon, Killarney and others, while Lady Alice Stanley and Grand Duc Adolphe de Luxembourg have the brilliant colouring and sweet scent, but not the pointed form.

One of the most beautiful of the new Roses in the Seedling Tent at the National Rose Society's Show on July 7 was Mrs. George Norwood. This variety is of a soft shade of pink, of fine form, with high pointed centre, and, to crown all, a quite remarkable fragrance. It was also shown among the new Roses competing at Holland House for the Clay Cup, to be given to the Rose possessing in the most marked degree the true old Rose scent, and was the only one in this class which combined lovely form and colour with exquisite fragrance. The successful Rose was Queen of Fragrance, a wide open, flat flower with a blush pink centre, brought out by Messrs. W. Paul and Son of Waltham Cross. The competition was an interesting one, though the specimens in the class when I saw them on the second day looked so tired and jaded that there was little to recommend them except their fragrance. The variety which apparently had the power of retaining this quality the longest was one of Messrs. Alexander Dickson's called Mrs. Bryce Allen. It had, as seen that day, dull pink flowers of the old-fashioned flat shape, but its scent was most delicious.

The judges of the new seedling Poses at the National Rose Society's Show were instructed to consider the fragrance as well as the form and colour of the Roses before them. This will doubtless encourage the hybridists to try to propagate from those varieties which are most sweetly scented, and so to retain the real old Rose smell as one of the principal features of the Queen of Flowers.

WHITE LADY.

[We suggest that the judges of new Roses for fragrance should be blindfolded. Perhaps "White Lady" will get some friend to test fragrance when blindfolded and note the interesting results. The same flower has been declared less or more fragrant when given to a blindfolded judge the second time! —Ed.]

WORK AMONG THE AURICULAS.

THE Auriculas will now begin their second season of growth, and if we are to secure a good truss of bloom next April we must encourage the plants in every way possible, for what is known as "a good autumn growth" is most essential. The subject of this series of articles ought not to be coddled in the least, and the treatment given now and during the autumn months will play an important part later on, especially when we come to the most critical months of November and December. Full exposure to the air should be the rule, excepting, of course, during heavy rain which is likely to make them very wet at the roots. Green fly must be kept down and all dead leaves should be removed, while the usual precaution ought to be taken in regard to the watering pot.

Offsets.—These are taken off twice a year, viz., in February and August. I always try to make a general examination of the plants during this month, and take off any of the offsets that are large enough for removal. If the variety is a fairly common one and no more stock is required,

they are thrown away or planted out in a small nursery bed, where they remain until they are fit to be removed to the rock garden or ordinary flower border. With a choice kind the reverse is the order; each offset is placed in a pot and carefully tended, so as to bring it to the flowering stage in the shortest possible time. Good varieties sometimes produce offsets very slowly, and this fact should be borne in mind when purchasing some of the best in the market. As a rule it takes an offset from eighteen months to two years to attain full size, while seedlings take about the same time. Some of the offsets that were potted up in February may require a move on, and where such is the case the present is a suitable time to carry it out, using the same kind of soil as advised in the article that appeared in May. Each plant should be examined, and if the surface soil has become hard or sour, it can be pricked up with a pointed stick. This not only gives them a much neater appearance, but is also of considerable benefit to the plants.

The Brown Grub.—Happily, this pest does not often make its appearance where the best loam and clean leaf-mould are employed as a rooting medium. It usually attacks the plants in early autumn, and, if any are looking sickly, this may be the cause, or perhaps the tap-root has begun to decay. The soil must be shaken from the roots and the stem exposed, when it can easily be ascertained what is doing the mischief. Before repotting in fresh soil, and in all probability a smaller receptacle, the stem must be cut back if decayed and the grub destroyed, or it will bore its way right through the centre of the plant. There is no need to repeat the details given in past months, but I strongly advise the grower to treat the Auricula as a plant, and by using ordinary common sense and striking what is popularly known as the happy medium in cultural matters, the results will be most satisfactory.

T. W. BRISCOE.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

IRIS (E. M. H.).—The Iris is *I. ochroleuca*, and is also known as *I. gigantea*. It is a proverbially shy-flowering plant, and, resenting much root disturbance, requires age before it flowers at all. It is occasionally seen under the most opposite conditions of dry and wet, sun and shade, and behaving much alike in all. Some of the finest examples we have seen, however, were in light, rich loam in full sun. The plants reached 6 feet high and flowered splendidly, after which for three years they took a rest and gave but few flowers. All you can do is to encourage good growth by early summer watering and a free use of liquid manure or guano-water. It is a plant for experiment, and one for which it is difficult to lay down hard-and-fast rules.

ROSES WITH BAD CENTRES (Reigate).—There are very many crippled flowers this season, owing, we believe, to the late frosts and altogether bad weather in many parts. It is unwise in such a season to be in a hurry as to disbudding, as we are apt to retain the central bud, which is too often damaged. As you gave the Roses the various ingredients you name in the winter and early spring, you have somewhat overdone it in giving the other

articles alternately once a week. Had you kept the cow-manure in liquid form, you would probably have had better quality blooms. A dozen good reliable exhibition Roses, avoiding white and cream, are Gloire de Chedane Guinoisseau, Avoca, Margaret, Lady Ashtown, Mrs. Wallace Rowe, Hugh Dickson, Marquise Litta, Mrs. Walter Easlea, Lohengrin, Lady Ursula, Exquisite and Ulrich Brunner.

BEGONIA FLOWERS DROPPING (H. E.).—It is difficult to assign any reason for the flowers of your Begonias dropping in the way described. The plants may have suffered from drought, a likely cause of the trouble, for hot, dry weather such as we have experienced this summer is not to the liking of tuberous Begonias. For this reason, and in order to ensure a regular condition of moisture, many cultivators mulch the beds of these Begonias with Coconut refuse or leaf-mould.

DIVIDING PRIMULAS (Wills).—The Primulas may be divided at any time after flowering, and the present is suitable, provided you can give them the requisite attention in watering and shading for a week or two following the operation. Both *P. rosea* and *P. japonica* revel in moisture-laden soils naturally, and, in addition to abundant root moisture, should be afforded free sprinklings overhead for some days after dividing the plants. *P. frondosa* also delights in moisture, though in a lesser degree. All three may be raised from seeds, and that is the better way of ensuring great vigour in the plants. Tiffany, scrim or thin canvas of varying qualities and prices are usually stocked by nurserymen and seedsmen, and your better plan would be to send a request to some of these for samples, or for their catalogues, which as a rule contain them.

PLANTS FOR FLAGGED WALKS (Spade).—The really suitable plants for this purpose are not numerous, and those available from seeds, or that soon make their presence felt, less so. In a very considerable number of instances we find tufted and cushion mounded subjects, over which it is not possible to step in the usual way, and others flowering at 1 foot or 15 inches high, all too freely employed, with the result that the "path" is in the nature of a "flat rockery." Some of the dwarfest and most suitable are given below, those available from seeds being marked by an asterisk: *Arénaria balearica*, *Campanula muralis*, *C. pusilla*, *C. p. alba*, *C. pulla*, *C. garganica* (three varieties), **Dianthus squarrosus*, **D. cæsius*, **Draba aizoides*, *Erinus alpinus* in all its forms, *Helxine Solierolii*, *Leptinella scariosa*, **Linaria pilosa*, *Mentha Requienii*, *Myosotis rupicola*, *Sedum brevifolium*, *S. corsicum*, *S. hispanicum glaucum*, and *Thymus Serpyllum coccineum*. At the sides of the walks, where little or no treading is likely, *Corydalis lutea*, the dwarfest of the Mossy and other Saxifrages, and alpine *Dianthus* might also appear. Much, naturally, depends upon circumstances.

PLANT FOR BEDDING (S. W.).—If you are contemplating a bedding plant that could be grown in reserve and transplanted into the intended position, we are afraid we do not recall anything likely to be of service. The Sweet William would not be in flower till late June or early July, and, moreover, does not transplant well in the advanced stages of growth, when flowering-time is approaching. You might, of course, plant with spring bedding subjects in the autumn the Persian *Ranunculi* in variety, which would afford a useful succession, flowering in your district in June, or in December or January the St. Brigid *Anemones*, which would flower in May and June. These only need dibbling 2 inches deep into the soil, or, by growing the plants in pots, they might be introduced without disturbance when convenient. Or you might effect a sort of compromise by planting, 8 inches or so deep, Emperor, Sir Watkin or other *Daffodils* permanently, and, as surface carpeters, Tufted Pansies of shades distinct from the *Violas*. By planting the *Daffodils* in September and the *Violas* (Tufted Pansies) in October, the beds would be covered during the winter and a good flowering ensured throughout April, May and June. Then, by starting the Begonias early in boxes, giving them plenty of room, these, with the surface cleared of *Violas*, could be put out practically in bloom. The above are merely suggestions, and are made without knowledge of what bedding plants you employ. If you gave us the names of these and the size of the beds, we might further assist you.

PRUNING ANCHUSA (Dion).—The main shoots of *Anchusa italica* are shortened to dwarfen the plant previous to the expansion of any flowers, the effect of which is that the axillary growths below the parts excised, many of which would otherwise never shoot, are forced into vigorous growth, but more in a horizontal than in a vertical direction. The more forward of these, as they exhibit signs of seeding, are also cut back to a new set of growths which issue lower down the stems of these, and so on as long as the vegetative powers of the plant are in such vigour as to induce the production of successive axillary growths. The limit is reached according to the cultural treatment of the soil, which, if of the best, will continue to the end of the season. It may be of interest to note that there is a comparatively large section of herbaceous plants which can be rendered considerably dwarfier than they naturally are under high-class cultivation by adopting the above expedient. The uncommon but not useless *Gypsophila Rokejeldii* is one such which, left to itself, grows out of all proportion to be of benefit in an ordinary herbaceous border. It can be kept quite low by repeated pinching. The varieties of *Anthemis tinctoria* afford an example of what may be effected to produce a variety just by simple manipulation of the plants. Plants left to themselves will grow to 7 feet or 8 feet in height, and on occasion are useful then. By cutting at the proper stage, plants not exceeding 3 feet in height are possible; or by planting wide and pegging down the shoots the same end is attained. Some of the

varieties of *Chrysanthemum maximum* grow much too tall to be generally useful, but instead of cutting these we prefer to replant annually, the spring planted being much dwarfier than those planted in the autumn. To revert to the question of pegging, *Linaria Panceicii* when pegged down forms a low mass of lovely colour. *Aster acris* is perhaps as distinctive pegged as treated in any other way. *A. Climax* is another well-known variety that repays growing in this way, and autumn-flowering *Chrysanthemums*, if pegged at an early stage of growth, also produce striking masses of bloom. But really there is a large number of plants that may readily be made to assume different and distinctive habits of growth by these means. Let us note in conclusion that those plants which become hard in the stem should be cut back previous to that stage.

THE GREENHOUSE.

FUCHSIA WITH ABNORMAL FLOWERS (G. P.).—It is impossible to state the reason of your Fuchsia producing such depauperated blooms, though such freaks of Nature are occasionally met with. We have known it occur in several Fuchsias, but never before in the variety Gertrude Pearson. How best to restore the plant to its normal condition is a somewhat difficult problem, and unless particular interest is attached to it we should be inclined to burn it. Should you, however, desire to give it another chance to mend its ways, we advise you to pick off all flowers and buds and repot, at the same time taking away as much of the old soil as can be done without unduly distressing the roots. Potted in a mixture of loam, leaf-mould and sand, it will soon become established and commence to grow and flower, when the blossoms may revert to the normal type. On this point, however, there is some doubt, though the experiment may be well worth trying. We much appreciate your kind remarks re THE GARDEN, as our aim is to render it of value for all classes of gardeners.

MISCELLANEOUS.

MILLIPEDES ATTACKING MALVAS (Ragatt).—The pest attacking the Malvas and Clarkias appears to be the flattened millipede, *Polydesmus amplanatus*. These are usually most abundant when the soil is sour, and may be captured by burying pieces of Potato, with a stick piercing them to mark the sites of the traps, examining them each day and killing the captives.

SILVER-LEAF DISEASE (Kent).—There is no fear of the silver-leaf disease spreading from one tree to another while the affected parts are alive. The fungus which causes it fruits on the dead stems, and it is from these that the evil spreads. All affected stems should, therefore, be burned. Stone fruits are most affected, but almost any kind of tree is liable to fall a victim. We have not met with it on Currants or Raspberries.

WASHING VEGETABLES FOR EXHIBITION (G. H. H.).—All vegetables are best washed just before they are staged in the show tent or building. They must be washed just long enough to allow them time to dry before being packed for conveyance to the show. If the latter is close to the gardens where the vegetables are grown and special packing is not necessary, then wash the roots on the morning of the show, as they dry very quickly. If they are to be packed, wash Potatoes and roots, dry them, and then wrap each one in clean white paper. A brush should never be used in preparing vegetables for exhibition. Soak the specimens in water and then sponge them. A syringing is beneficial, especially in the case of Celery and Leeks.

NAMES OF PLANTS.—J. P., Scalby.—Hybrid Tea Rose *Princesse de Bearn*. The other plant is *Swainsona canescens*.—**H. A. D.**—The Rose is *Pharisæer*. Many thanks for your kind remarks.—**J. C. A.**—Rose *Mme. Bérard*.—**L. Johnston.**—*Hyoscyamus niger* (Henbane).—**F. T. Coates.**—White, Carnation *Mrs. Eric Hambro*; buff, *Viscountess Ebrington*.—**F. B. M.**—1, *Betula lutea*; 2, *B. lenta*.

* * * Owing to the Bank Holiday, this issue had to go to press several days earlier than usual, and consequently many names of plants are held over until our next issue.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

At the fortnightly meeting held at Vincent Square on Tuesday, the 28th ult., there was a good display of flowers and fruit, but visitors were far from plentiful. Thanks to the efforts of the National Gladiolus Society, a great many non-competitive groups of these beautiful bulbous flowers were staged, the most interesting of all being the beautiful *primulinus* hybrids.

ORCHID COMMITTEE.

Present: J. G. Fowler, Esq. (chairman), Sir Harry Veitch, and Messrs. James O'Brien, W. Bolton, A. McBean, T. Armstrong, J. E. Shill, W. H. Hatcher, Arthur Dye, E. H. Davidson, Gurney Wilson, Charles H. Curtis, S. W. Flory and Richard Thwaites.

Messrs. Charlesworth and Co., Hayward's Heath, showed very good examples of *Odontoglossum Rolfeae*, *Catasetum macrocarpum aureum*, *Cattleya Rex*, *Lælio-Cattleya colmaniana*, together with a variety of *Cypripediums* and *Cattleya Fauna*, whose buff-coloured, purple-lipped flowers were very beautiful.

From His Grace the Duke of Marlborough, Blenheim Palace, Woodstock, came the fine *Vanda cærulea Graci*, a very beautiful pale blue form. Silver Flora medal.

Messrs. Sander and Sons, St. Albans, had nice flowering specimens of *Masdevallia Carderi*, *Anguloa Cliftonii*, together with *Cypripedium Franconia superbum*, *Lælio-Cattleya Hiawatha* and *Epidendrum radiatum* among many things.

Mr. J. Gurney Fowler, Pembury, Kent, received awards of merit for *Lælio-Cattleya Miss Louisa Fowler* and *Cattleya hardyana rubens*, both choice and good. Silver Flora medal.

Baron Bruno Schröder, Englefield Green, had the fine white *Cattleya Astron*, an exquisitely beautiful plant. See "New and Rare Plants."

Mr. H. Goodson, Putney, showed *Oncidium Leopoldii* Fairlawn variety, the plant carrying a long raceme of flowers.

Mr. R. G. Thwaites, Chessington, Streatham Hill, had nice examples of *Odontioda Thwaitesii* (with a spray of rich purple flowers), *Odontoglossum Pescatorei* and others.

FRUIT AND VEGETABLE COMMITTEE.

Present: J. Cheal, Esq. (chairman), and Messrs. W. Bates, Edwin Beckett, A. Grubb, J. Willard, J. Davis, A. W. Metcalfe, J. Jaques, A. Bullock, G. Wythes, P. C. M. Veitch, John Harrison, C. G. A. Nix, A. R. Allan and George Kelf.

A magnificent collection of pot-grown fruit trees, comprising Apples, Pears, Plums, Peaches and Nectarines of the highest excellence, was staged by Messrs. James Veitch and Sons, Limited, Chelsea. The group was arranged on the floor opposite the entrance, and was probably the finest ever staged by this eminent firm. In not a few instances the trees were simply loaded with fruits, at once a demonstration of high cultural skill and a tribute to British horticulture. In all there were about six dozen trees staged, the majority of pyramidal outline; the others—Peaches, Nectarines and their like—in fan-trained examples, reaching to 8 feet or more across. Of the Plums there were a dozen examples of Jefferson's, four of Kirke's, seven of Early Transparent Gage, literally loaded with fruits; while such as Green Gage, Red Mirabelle and Oullin's Golden Gage were all represented. Of Pears there were some half-dozen sorts, Durondeau, Williams' Bon Chrétien, Souvenir du Congrès and Louise Bonne of Jersey being some of them. Apples Wealthy, Lady Sudeley and James Grieve, the second named brilliantly coloured, were also noted. Of Peaches there were six trees of Peregrine, two of Violette Hative and one of Duke of York; while the Nectarines found admirable representation in fine examples of Early Rivers, with others of Pineapple, Lord Napier, and Pitmaston Orange. Hence it will be seen that the collection was both good and varied, a fine demonstration of what is possible with the cultural skill which now prevails. A gold Hogg Memorial medal was deservedly awarded.

Messrs. S. Spooner and Sons, Hounslow, showed Apples Red Astrachan, White Transparent, Mr. Gladstone, Early White Magnet and Early Victoria. Pear Citron des Carmes was also shown.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. C. T. Drury, E. A. Bowles, R. C. Notcutt, James Hudson, F. W. Harvey, J. Green, T. Stevenson, J. W. Moorman, J. F. McLeod, W. Howe, A. Turner, C. Dixon, J. T. Bennett-Poß, C. E. Shea, C. E. Pearson, W. P. Thomson, W. G. Baker and E. H. Jenkins.

From Messrs. James Kelway and Son, Langport, Somerset, came a fine table of *Gladioli*, the quality of the exhibits finer than we have seen for a long time. Obviously the weather conditions experienced this year have proved congenial to these plants, both the flowers and the spikes being excellent. The group was composed chiefly of *gandavensis* hybrids, with a few others into which *primulinus* influence had freely entered. Some good sorts were John Churchill Craigie (yellow and scarlet), Sir M. W. Ridley (crimson), Countess of Suffolk (crimson, pink and yellow), General Henderson (flamed scarlet and crimson), Yellow Prince, Golden Measure, Golden King (rich yellow with crimson base), Lady Rosemary Portal (ivory white) and Mrs. G. W. Willock (pink and white). Golden Girl and Banshee are *primulinus* hybrids, very beautiful in yellow and bronze pink.

Mr. L. R. Russell, Richmond, showed a collection of *Celosia pyramidalis* in three shades of red and tall and dwarf yellow. A full table was occupied by the admirably grown examples. Silver Banksian medal.

Mr. C. Engelmann, Saffron Walden, was the only exhibitor of *Carnations*, showing in admirable form such as Elektra (orange), Carola, Scarlet Carola, White Wonder and Circe (heliotrope, fancy). Silver Banksian medal.

Messrs. Atkinson and Statter, Southampton, showed two semi-circular, tastefully arranged groups of *Gladioli* on raised stepped staging. The arrangement was artistic in the extreme, and, moreover, displayed this fine garden flower to considerable advantage. The ground colour of the arrangement was grey, the light sprays of *Gypsophila* associated therewith harmonising beautifully. Some of the leading sorts were Golden King, a centre of this, some fifteen spikes in all, making a glorious display. The variety has deep primrose yellow flowers with crimson base. Blotch is scarlet and white, a fine contrast; Orby, crimson scarlet; Goldfinder, yellow; and Loveliness, flesh white to pink with yellow shading, a magnificent variety. Excelsa (pink), Pink Beauty (with crimson blotch), and Armagnac (crimson, white throat) were others noted in a fine lot.

Mr. Howard H. Crane, Highgate, N., had a very fine collection of *Violas* and *Violettas*, showing them in his usual style in pans of sand and water. Of the latter, Claribel (pale blue), Forget-me-not, Rock Orange, Cynthia (mauve), Rock Lemon, Violetta (white) and Neapolitan were all good and choice. Bronze Banksian medal.

THE GARDEN.

No. 2230.—VOL. LXXVIII.

AUGUST 15, 1914.

NOTES OF THE WEEK.

Flower Shows Cancelled.—Owing to the present crisis, a number of flower shows have been abandoned, including the fortnightly meeting of the Royal Horticultural Society (arranged for August 11). We also understand that the flower shows at Shrewsbury, Carlisle and Taunton have been cancelled.

The Cultivation of Vacant Land.—The Development Commissioners desire to suggest to landowners in England and Wales that they should at once forward to the Agricultural College for their province particulars of any waste land which they are willing to place at the disposal of suitable authorities for improvement by such means as reclamation or afforestation. The particulars of the land should include situation, approximate area, elevation, character of the soil and the terms on which the land can be obtained by an authority willing to improve it.

Early Celery.—Attend to the earthing up of the earliest planting; but on shallow soils brown paper collars would serve the purpose just as well. If, however, the latter are used, the plants must have abundant supplies of water at the roots. Paper collars, of course, should only be used for the earliest crop.

The Madonna Lily.—It is generally admitted that to succeed in the cultivation of the stately Madonna Lily it should be left undisturbed as long as possible. For this reason it is often seen at its best in cottage gardens, where for year after year it remains in the same place, almost without attention. Transplanting is sometimes a necessary evil, and in such instances it should be accomplished towards the end of August, planting in a full sunny position, 4 inches to 5 inches deep, in good soil to which lime has been added.

Pruning Climbing Roses.—When the plants have ceased blooming, many of the old shoots may be cut away to make room for the young growths to be trained in their places, and nothing should be tied into position beyond that which is necessary to furnish the trellis for another year, as, by crowding the shoots now, many of them never become ripened, and the result is almost sure to be unsatisfactory. There are many charming varieties to choose from, which may be trained in different ways or allowed to ramble at will over an old wall or up a decaying tree stump, where they present a very pretty appearance.

In such seasons as this a liberal supply of water should be given at the roots.

Labour Exchanges and Harvest.—The Board of Trade Central Office for Labour Exchanges are making special arrangements for the supply of farm hands, &c., required in connection with the harvesting season. All farmers and other employers who are desirous of engaging this class

afterwards met the whole of their employes at the regular morning prayers, when it was announced by the senior partner that the welfare of the wives and families of those called on to serve their country would, during their absence, be cared for by the firm, and the places of all would be kept open. "God Save the King" was heartily sung.

A Handsome Biennial.—*Gilia coronopifolia*, a plant that has come to the front a good deal of recent years, should be in all gardens. It is a very handsome biennial, bearing large spikes of brilliant salmon-scarlet flowers, a colour so valuable in gardens. It forms pretty, compact tufts of elegant Larkspur-like foliage, and during its second year a strong shoot commences to grow from the centre, which about August attains a height of from 2½ feet to 3½ feet. The flowers are most gracefully arranged on the main flower-stalk and last in bloom for a very long period, frequently commencing to open in July and continuing into October. It is readily raised from seeds, and at the present time is one of the most brilliant plants in our garden. Seeds of the white Swan River Daisy (*Brachycome iberidifolia* White Star) were sown among the plants when they were put out in the spring, and the two are now in bloom together, forming a mass of beauty.

Preserving Vegetables and Fruit.

At a period such as this, when we are in the throes of a European war, it is the duty of everyone to be as economical as possible with all kinds of food. Fortunately, our vegetable crops this year are good, and in some places fruit also can be had cheaply. With a view to assisting our readers in preserving these two important kinds of food, we hope next week to publish articles on the storing of vegetables

for winter use and the bottling of such fruits as are still obtainable. As the Rev. W. Wilks and Professor Keeble point out, it is not too late to sow Turnips and Carrots, which, given a favourable season, will yield crops of succulent roots for use in winter. Plants of such greens as Sprouting Broccoli, Russian Kale and Savoy Cabbages, where obtainable, should also be planted, and more closely than they would be earlier in the year.

A GROUP OF MADONNA LILIES LEFT UNDISTURBED FOR MANY YEARS

of labour should communicate their wants to the manager of the nearest Labour Exchange, the address of which can be obtained from the local post office. It should be remembered that no fees are charged, either to employers or employes.

Seedsmen for the War.—At the Royal Seed Establishment on the morning of the 5th inst., Messrs Sutton of Reading took a personal farewell of the Reservists and Territorials among their staff, and

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Recipe for Lavender Water Wanted.—Would any of your readers give a recipe for home-made Lavender water or Lavender essence? as I should much like to know if it is possible to make at home, and what utensils would be required for doing so.—M. H. A.

Annuals for the Rock Garden.—On page 387, issue August 1, you draw attention to two of the lesser-known annuals suitable for a rock garden. May I supplement them with three other sorts, perhaps not so rare, but really good things, though seldom, when compared with the mention of other annuals, spoken of. They are *Eschscholtzia tenuifolia*, *Leptosiphon hybridus* and *Sedum cæruleum*, all of which are flowering now, and, coupled with being so dwarf and neat, may claim to be veritable gems for any rockery or wall. The flowers of the first named are primrose coloured, which are well set off by the finely-cut, greyish-hued foliage out of which the spikes spring up. *Sedum cæruleum* tells its own colour, and I will only add that it blooms most freely where root action is limited, in which position also the foliage assumes a more bronzed appearance than where a deep soil abounds. The *Leptosiphons* are variously coloured and range in height from 3 inches to 6 inches, as I do not here include the variety *densiflorus*, which is a foot high or more. Three inches to 6 inches also covers the height of the *Sedum* and *Eschscholtzia* referred to.—C. T., *Highgate*.

Japanese Irises in a Cheshire Garden.—I send you a photograph of Japanese Irises growing at the edge of my pool. Some are growing in the water, the greater part of them, and some on the bank. The chief enemies of the Iris are the water-rats, and I have to protect the plants with wire, as shown in the photograph. The Irises have done exceptionally well this year, due most likely to the mild winter and hot spring and summer, each clump having a dozen or more spikes of flowers, which are of every shade and variety.—GEORGE DIXON, *Astle Hall, Chelford, Cheshire*.

Gypsophila paniculata flore pleno.—The doubling process has an unfortunate tendency in certain varieties of plants to detract from, rather than improve, the appearance of the blooms; but in the case of the subject under notice the alteration is a distinct improvement, which, while retaining the cloud-like characteristic and free-flowering propensity of the old variety, has made it quite a different-looking plant. Whereas the single form appears greyish white, soon turning to dirty white when cut, the variety under notice bears snow white masses of perfectly double blooms. Most useful in conjunction with any other flowers for decorative effect, either in vases or epergnes, it is well worth a place in the herbaceous border. When dried, the flowers retain their whiteness throughout the winter; hence the variety possesses the additional advantage of being practically an everlasting. Vases of last

season's gathering are before me as I write, waiting to be replaced by the current year's flowers now just coming into bloom. One tie all round the plant in the early stages of its growth will be found sufficient to keep the thread-like stems erect throughout the season. *Gypsophilas* like dry soil impregnated with mortar rubble or limestone matter.—B. W. LEWIS.

The Shrubby Candytufts.—These are capital dwarf evergreen shrubs for growing in the rockery, where they soon form fair-sized clumps of dark green foliage and invariably flower with great freedom. A good-sized group of these hanging over the face of a steep declivity looks when in full bloom like a drift of snow, so pure is the whiteness of their blossoms. There are quite a number of varieties, all of them worth growing; but I wish to call attention to two especially handsome sorts, which should be in every garden, no matter how small. The first is *Little Gem*,

JAPANESE IRISES BY THE WATER-SIDE IN A READER'S GARDEN.

a neat, compact-growing little shrub, forming a beautiful cushion of emerald green, a highly attractive feature at any period of the year; but in spring, when it expands its snowy blossoms, the cushion is changed from green to one of purest white. The other variety is *Snowflake*, a much stronger grower, and therefore suitable for planting in larger spaces where it will have plenty of room to expand. The flowers of this are produced in great profusion, every shoot carrying a large truss of snow white flowers, which last a long time in good condition. The Iberises are easily increased by cuttings taken in the late summer or autumn and rooted in a cold frame.—W. L., *South Ayrshire*.

Ourisia coccinea and Its Cultivation.—There are few plants which are so much admired as *Ourisia coccinea*, yet are so disappointing to the average cultivator, especially to those who

try to supply it with its apparent requirements. The writer knows of many people who have tried and failed with this Chilean subject, whose bright scarlet trumpets are so beautiful. On the other hand, it is a mystery to see it doing well in some garden where, though the conditions are such as are suitable for good border flowers, there seems no reason why *O. coccinea* should do well there and fail in other places where its supposed needs are more attended to. It is strangely fastidious, and while no one need ever despair of succeeding with it, nobody can feel absolutely confident of success. The writer knows of one garden where it thrived amazingly in one place, but pieces removed to another and apparently similar position in the same garden sulked and died off. On the other hand, one finds *O. coccinea* flourishing in some places in moist peat; in others in loam, sand and leaf-mould; and in still others in ordinary loam in a mixed border. If there is any reliable treatment, nobody appears to have hit upon it yet, and the longer one knows the plant and sees it growing or failing to grow, the more does one feel the limitations of human knowledge and the more diffident of giving advice with regard to flowers such as this. These thoughts are induced by seeing this plant flourishing in several Berwickshire gardens, such as that of Mr. Hay at Duns Castle, Duns, where it appears to give no trouble in the border among other hardy flowers, and makes generous clumps.—S. A.

Laurel Leaves as an Insecticide.

It may interest some readers to know that the leaves of the ordinary Laurel can be used as an insecticide in a small way. These leaves contain a chemical substance known as a glucoside. When they are broken up, bruised, or have the tissues torn asunder, fermentation takes place immediately afterwards and the glucoside is decomposed, while the deadly hydrocyanic acid gas is evolved at the same time. The gas spells death to all insects, and so the leaves may quite usefully be employed for fumigating small places or single plants. I have often used these leaves to treat some individual plant in the greenhouse, and for the purpose I keep a tall box rendered fairly air-tight by means of putty; this I cover over with glass. A good

handful of the leaves are gathered as required, and bruised thoroughly by being beaten with a wooden mallet on a block or brick. This brick, with the leaves on it, is placed inside the box along with the plant, the top covered up and left so from sunset until early the next morning. No damage has ever been done to the plants, and the result is always satisfactory. I have fumigated plants under a bell-glass in this way successfully, and have tried it in a frame and in a propagator with varying success, failures being accounted for by imperfect closing of the sash. Naturally, this method of fumigation has its limitations, and is often carried out because of its uniqueness rather than for its practical utility; but it may recommend itself for single plants suddenly infested with insects in destructive numbers.—H. H. A.

TWO BEAUTIFUL LILACS:

White: Marie Legraye.

Purple: Souvenir de Louis Spathe.

White Rose Ointment.—Will it interest any of your readers to know that the pipkin as spoken of by "Anne Amateur" in various numbers of THE GARDEN and illustrated in August 1 issue can still be obtained, and very cheaply and in various sizes, at Mead's Pottery, Burgess Hill, Sussex? Made with flat bottoms, the pipkins are useful for stewing fruit or making porridge, and in our house they have been so used for many years.—GRACE GARDINER.

Erodium corsicum.—This delightful alpine gives much promise of geniality and freedom of growth and flowering; hence will be welcomed by all who find pleasure in the dwarf carpeting subjects, whose rightful place is the rock garden. Happily, too, it is a free seeder, so that there is no need for a solitary 3-inch-wide example to represent—or misrepresent—a plant that should appear in yard-wide patches. The warmth of its rosy red flowers, too, is very welcome, and against the spreading carpets of hoary crenated leaves is pretty indeed. In short, it is a dainty as well as meritorious plant, whose profuse flowering but adds to its many good attributes. For a sunny sloping position in the rock garden it appears particularly well suited.—S.

Rose Trier.—There are certain varieties of decorative Roses only occasionally seen at the shows which many gardeners with none too much room to spare for experimental purposes are shy of trying except under strong personal recommendation by those who have grown and proved them. Among such a class as this may be included the splendid Polyantha variety Trier. A semi-double, most floriferous Rose, in colour creamy white with pink-tinted centre petals, it is suitable for covering an arch or pergola, or it makes a grand pillar. The flowers, which are borne in pyramidal clusters on the points of the lateral shoots, have a gentle perfume, very noticeable in the evening. In addition to its very pleasing bloom, a specific charm about this variety is its profusion of handsome dark green foliage, carrying a distinct gloss. This foliage is of the everlasting type; hence the plant remains a thing of beauty the whole year round. Altogether it is a Rose highly to be recommended—a Rose possessing practically no faults and very many virtues.—B. W. LEWIS.

The Feather or Plume Hyacinth.—Mauves and lavenders are now such popular colours that I wonder we do not hear more of the Feather Hyacinth (*Muscari plumosum*). I believe it is quite hardy in the warmer parts of Great Britain in a light soil; but it has never yet been my good fortune to see it flourishing out of doors. I have, however, grown it for a number of years in pots, which are wintered in a cold frame, and then, at the commencement of March and onwards, I bring them, in batches, into gentle heat. Then the curious, dead-looking arrangement that we see at the bottom of the leaves first slowly rises upon a thin, wiry stalk, and afterwards, when this has reached a height of 8 inches or so, begins to expand in a curious, weird way, giving but little indication for a day or two of the dainty plume-like-looking head which it will have when fully expanded. It looks extremely well arranged with Maidenhair Fern or Asparagus Sprengeri, and lasts a very long time in a fresh condition. Botanically, it is not a flower or a flower-head of any kind. The head is really a collection of thin, slender branches borne on others a little thicker than themselves, and these, in their turn, borne on the wiry central stem. Morphologically, they may be some part or parts of a flower, but they do not look like it.

I once asked a gardener how his Feather Hyacinths were getting on. He said, "They all went wrong; the flower-spike never seemed to develop, and it looked half dead. So I threw them away." He did not know their slow—very slow—ways or the curious, withered, half-dead look that they affect. Anyone who wants to grow a cheap novelty in pots next year should try a hundred of these. Not only are they nice for cutting, but I find them very useful in pots for places in the sitting-rooms or hall, where small pots are wanted. Five in a 5-inch pot—or, if the bulbs are very strong, only four—make a good show. Cost of bulbs, 2½d. or 3d. !—JOSEPH JACOB.

The Pyracantha as a Flowering Shrub.—When the blooms of our own native Hawthorn are over or nearly so, the Pyracantha unfolds its masses of white blossoms. Though in this stage it is certainly less showy than in the autumn, when laden with its brilliant scarlet berries, yet in spring or early summer its beauty is such as to claim due recognition. That the Pyracantha with its two attractive phases forms a very desirable shrub in the open ground is not recognised to the extent it might be. Unfortunately, under such conditions the birds are, as a rule, even more destructive to the berries than they are when the plant is trained to a dwelling-house. What an acquisition it would be if a Pyracantha could be raised with berries distasteful to birds! From an ornamental standpoint some forms are decidedly superior to others. From this circumstance seedlings, which are notoriously variable, should not be planted, but specimens obtained from cuttings of the best kind. They are best grown in pots till planted permanently. Another advantage of plants raised from cuttings is that they flower and fruit in a smaller state than seedling.—H. P.

The Herbaceous Lupine.—The old-fashioned herbaceous Lupine, *Lupinus polyphyllus*, is now coming into its own as a garden flower. A very few years ago we had only two or three blue forms, some white ones, and the blue and white one called bicolor or Foxii. But the seedling-raiser has been at work, especially since the introduction of the pink or rose-coloured Lupines, and now there are many colours and shades. Mr. Amos Perry, Messrs. Barr and Sons (Mr. J. W. Barr being particularly keen on the improvement of the Lupine), Messrs. Cheal and Son, and others have been at work and have sent out some beautiful flowers. In private gardens some keen amateurs have been at work, and I saw a lovely set of seedlings in a Scottish garden the other day. These had originally come from a small packet of seed, the produce having been seeded, and the progeny of these selected and employed as seed parents also. Pinks, purples, whites, blues, bicolors, and yellowish shades were among them. There was a lovely primrose-coloured one, prettier than any shown at the London shows of late. The work is still going on, and it is difficult to say where it will end. The spikes have also been much improved in size and symmetry.—S. ARNOTT.

FORTHCOMING EVENTS.

- August 17.—Pitsmoor Flower Show. Sweet Pea Show at Sheffield.
- August 18.—Flower Show at Brighton.
- August 19.—Shrewsbury Show (two days).
- August 20.—Flower Show at Aberdeen (three days).
- August 21.—Flower Show at Forfar (two days).

WORK AMONG THE CARNATIONS.

HERE is yet time to propagate Malmaisons by layering, the reasonableness of late propagation being proved by the resulting plants, properly treated, never hanging growth as those rooted much earlier in the year not infrequently do. It is worth the extra trouble to layer into 2-inch or 3-inch pots, the plants receiving not the least check to growth by this method, and when properly rooted, repotting is easily effected into 4-inch or 5-inch pots. I use only a little flaky leaf-mould for drainage for the layering pots. It saves watering—and water is not of advantage to the layers—if the frames are shaded during direct sunshine. A little ventilation keeps the air fresh in the frames, and it is a curious fact that, as autumn approaches, the plants do well with more and more ventilation till the sashes can be dispensed with altogether in fine weather.

Perpetuals will all be properly staked before now, and there will be fairly constant attention needed to the tying of advancing shoots, which at this period grow amazingly fast, and if left untied for a day or two are sure to drop over, when it is impossible to straighten them once more. The circumvention of aphids is also a weekly affair. A box of Tobacco powder kept beside the plants is handy for dipping into or dusting on affected tips, or the plants may be sprayed with a proper insecticide; but on the whole I prefer the Tobacco powder, which does not affect the delicate bloom, so desirable to be perfect, on the foliage.

Manuring.—There are soils in which splendid Carnations are produced without the aid of manure, and which to manure would simply spell ruin to the plants. There are, however, less satisfactory soils in which the plants cannot be grown without applying manures at brief intervals, the time for commencing the application being indicated by the foliage assuming a less lively green than hitherto. The safe plan is to apply dressings or to water with manure-strengthened liquid before this stage is evident to the unpractised eye, and it usually occurs as soon as the pots in which the plants are to flower are well filled with roots. It is a very great mistake to use stimulating manures, sulphate of ammonia, for instance. The simplest material is soot. Well-diluted cow-manure solutions are satisfactory, while a number of proprietary manures suitable to the wants of the Carnation are to be had. Slight applications, it may be noted, are always to be preferred to larger ones.

Winter Quarters.—Towards the end of the month or early in September the plants will be relegated to their winter quarters. We have such a well-ventilated structure for summer growing that there is here no hurry to transfer them, the impossibility of giving abundant ventilation in the winter house being a decided disadvantage at this period. It not only brings on the blooms too rapidly, but the later growths are considerably weakened, so that by the time Christmas arrives, the plants are in a very depressed condition. The proper course to pursue would therefore be to give all possible ventilation night and day as long as the weather permits.

Tynninghame.

R. P. BROTHERSTON.

HARDY HIMALAYAN PRIMULAS.

(Continued from page 400.)

P. farinosa (Linn.).—It is unnecessary to say much about *P. farinosa*, which, as it occurs in Western Tibet and Chamba, at a height of from 12,000 feet to 17,000 feet, is practically the same as our native Bird's-eye Primrose. As with us, *P. farinosa* of the Himalayas frequents grassy hillsides and bogs. *P. farinosa* and *P. denticulata* have produced a hybrid called *P. Fortunei*, but this will not stand much frost, and should be grown in a cold frame.

P. geraniifolia (Hook.).—From the Chumbi Valley, Sikkim, at a height of 10,000 feet, we have *P. geraniifolia*, a close ally of *P. cortusoides*, with

base. Pax considers *P. Munroi* and *P. Traillii* as the same. In gardens *P. Munroi* has bluish and *P. involucrata* white flowers, with a yellow eye.

P. minutissima (Jacq.).—Here we have a tiny species which, with *P. Heydei* and *P. reptans*, form Pax's section *Minutissima*, but which Watt classes with the *Denticulata*. It is a minute *Primula* indeed, bearing two or three flowers on short scapes above the foliage. It is stoloniferous, with the leaves mealy beneath and with purple flowers. It is the only one of the section which seems amenable to cultivation here. It should be grown in an alpine house or frame.

P. obtusifolia (Royle).—This handsome species is closely related to *P. elongata*, and belongs to Pax's section *Callianthæ*. According to Sir George Watt, it is to be met with in Kunawar,

leaves, which are mealy underneath, are distinctly crenulate, and are produced after the flowers. The purple flowers have the petals entire or partially emarginate. According to some, *P. purpurea* is a variety of *P. Stuartii*, but the former has the fruit linear, erect and exceeding the calyx, while *P. Stuartii* has the linear fruit about the same length as the calyx, and the flowers of the latter are yellow and perfumed.

P. Reidii (Duthie).—One of the most exquisite sections of the *Primulaceæ* is that of the *Soldanelloideæ*, which gives us some fifteen or sixteen species. *P. Reidii* was first discovered by Duthie in Kumaon, and it was afterwards found in Chamba. It is still very rare in cultivation, but is a charming plant, with soft, hairy, toothed leaves, inflated calyx and deflexed flowers. The leaves are obovate-spathulate, and the flowers, though apparently very distinct in their arrangement from those of *P. capitata* and its allies, yet come closely to them in their dispositions. It is a beautiful little plant, with pale yellow or ivory white flowers. This gem should be treated as a biennial and cultivated under glass.

P. reticulata (Wall.).—Pax places *Primula reticulata* in the section *Cordifoliæ* and Watt in that of *Petiolaris*. It resembles in some respects *P. sikkimensis*, but is very distinct. The leaves are more cordate in form and have longer petioles. The scape of *P. reticulata* is proportionately longer, the corolla tubes narrower, the much exerted mouth annulated, and the fruit is ovoid. It thrives under the same cultivation as *P. sikkimensis*.

P. rosea (Royle).—Almost universally known, *P. rosea* requires no description here. It flourishes best by the side of water; but can be successfully cultivated in a small bog or in a moist border. Its brilliant rose purple flowers, which appear before the leaves, are of the most delightful colouring, and a mass of this plant is a fascinating sight indeed. In Nature it frequents sandy and gritty deposits of streams, and is undoubtedly much finer in moist than in drier places. It is perfectly hardy, but requires occasional division. Among the best varieties are *P. rosea splendens* and *P. r. superba*. *P. elegans* (Duby) is *P. rosea elegans* of Hooker f., and is a superior form of *P. rosea*. *P. rosea* occurs in the North-West Himalayas. It belongs to Pax's section *Farinosæ* and Watt's *Rosea*.

P. rotundifolia (Wall.).—Here we have a very distinct species, belonging to Pax's section *Cordifoliæ* and to Watt's *Petiolaris*. The leaves are mealy and rounded, cordate, with scapes about twice the height of the leaves and bearing two whorls of brilliant purple-pink flowers. It promises to be pretty hardy, and grows well in pots. It is plentiful in the Himalayas from Kashmir to Sikkim.

P. sibirica (Jacq.).—This has a wide distribution, and in one or more of its forms occurs in the Arctic regions of Europe, Asia and America, as well as in other parts of Asia. It is plentiful in the Himalayas, where it is found from Zanskar to Lahul at a height of from 13,000 feet to 15,000 feet. It is allied to *P. involucrata*, and has lilac or pink flowers. In cultivation it varies greatly in size and in the shade of colour. It sows itself and does well in the open. It belongs to Pax's *Farinosæ* and Watt's *Rosea*.

Morelands, Duns. JOHN MACWATT.
(To be continued.)

PRIMULA SIBIRICA, A HARDY HIMALAYAN PRIMROSE WITH LILAC OR PINK FLOWERS.

petiolate, pubescent leaves and having usually single umbels, but occasionally two, one above another. It has the lobes of the leaves acute. This species is rather liable to injury in winter, but is moderately hardy, and makes a good cold-house plant.

P. involucrata (Wall.).—This general favourite is practically the East Himalayan form of the widely spread *P. sibirica*, and is one of the easiest of all to cultivate in a moist soil. It is at home in the bog, in moist parts of the rock garden, or in the border. It dies down to the crown in winter, and may easily be destroyed at that season. It is so well known as to need no description, but may be said to have rather leathery, smooth, slightly glaucous leaves and slender scapes, carrying from three to six flowers in umbels. It is one of the so-called spurred *Primulas*, which have the pedicels embraced by an involucre of ascending parallel bracts, which are spurred at the

Kumaon, Sikkim and Bhutan. It has rugose, glabrous leaves, ovate or obtuse, and mealy underneath. On a slender scape about twice the height of the leaves it bears a many-flowered umbel of lilac flowers. In its native habitats it is very abundant, and gives off a strong metallic odour. A yellow-flowered form (probably a distinct species) is found at a higher altitude, and this has a delicate smell. I have an intense dark claret-coloured *Primula* with drooping flowers, which is, I consider, the most beautiful *Primula* that I possess. Although it has been grown as *P. obtusifolia*, it may be *P. Gammieana* (King), but this point I hope to make certain when it flowers.

P. purpurea (Royle).—This *Primula*, from Tibet, Lahul to Kumaon, at a height of from 10,000 feet to 14,000 feet, is a highly variable species, and considerable confusion exists regarding it. Pax calls it var. *macrophylla* of *P. nivalis*, but it is generally accorded specific rank. The

A FRAGRANT GUELDER ROSE.

VIBURNUM CARLESII is the daintiest member of the *Viburnum* family. It is a Korean species, and was first introduced to England in 1902 by Messrs. Louis Boehmer and Co., they having sent a plant to Kew after growing and propagating the plant in their Japanese nursery for twelve or thirteen years previous to distributing it. *V. Carlesii* forms a small, rounded bush up to 3 feet or rather more in height. The leaves are broadly ovate, the flowers pale flesh pink. These are deliciously fragrant, and borne in a closely packed, rounded cluster 2 inches to 3 inches across, lasting, during favourable weather, in good condition for from two to three weeks. Though quite hardy, the fact that the inflorescences commence to develop at the ends of the shoots in the winter and the flowers expand in April and May makes it desirable to select a somewhat sheltered spot for this treasure from Korea. Cuttings root fairly readily towards the end of July and during August in a propagating-frame with slight bottom-heat. For a year or two growth is slow, but, once the plants are 6 inches high, they produce shoots much more freely. The plants commence to flower when quite small. The most suitable soil is a well-drained sandy loam in which leaf-mould and peat have been freely mixed. A. O.

PHYLLOCACTI IN AUGUST.

ANYONE who hopes for a good display of these gorgeous flowers next year—and who does not?—should be careful as to the treatment given the plants at this season. Particular care should be taken that they are not shaded in any way, as by full exposure to the sun from now onwards depends their future show of bloom. They must be watered with moderate freedom, while an occasional dose of weak liquid manure will be helpful. As the branchlets of *Phyllocacti* are rather weighty, it is very necessary to see that they are effectually staked. The stakes, however, should show as little as possible. For most plants one will suffice, looping up the side branches to it. Should any pieces be accidentally broken off, they may be placed round the edge of a pot which has previously been well drained and filled with some sandy soil. Stood on a shelf in the greenhouse and kept moderately moist, these cuttings will root, and in spring they may be potted off singly. The mistake is sometimes made of withholding water for too long a period. In the growing season the plants require almost as much moisture as *Pelargoniums*. The established plants should not be dried off at any time; but even in winter enough water should be given to keep the soil slightly moist, increasing the supply as spring approaches. H. P.

COLOURED PLATE.

PLATE 1500.

THE LILACS AND THEIR CULTIVATION.

ALTHOUGH nearly three and a quarter centuries have elapsed since the common Lilac was introduced to our gardens, it is still one of our most beautiful and popular shrubs, and the opening of its blossoms is usually looked upon as the culminating point of beauty of the spring garden. And not only is it dear to the hearts of garden-lovers, for through

VIBURNUM CARLESII, A BEAUTIFUL AND FRAGRANT HARDY SHRUB FROM KOREA.

many generations its praises have been sung and its beauty extolled by poet and artist. Its peculiar virtues in regard to garden adornment need little seeking, for it is a vigorous shrub, perfectly hardy, will grow almost anywhere and, though of rather stiff outline when out of flower, the weight of its flower-heads at blossoming-time is sufficient to incline the branches into graceful lines without hiding the flowers. Moreover, the delicate shades of the flowers, together with their exquisite perfume, leave little to be desired from that aspect.

The Best Soil.—Lilacs thrive best in good loamy soil. They will also grow in sand, but do not bloom so freely as when growing in the better

material. Moreover, they pay for a little attention to feeding, and the more vigorous the current season's shoots, the better will be the flowers of the succeeding year. Thorough ripening of the wood is essential, and for this reason it is wise to give open and sunny positions as far as possible. Feeding may take the form of an occasional application of liquid cow-manure during May and June, or a surface-dressing of well-decayed manure may be given during the earlier month.

Propagation is conducted in a variety of ways. The types or species can be raised from seeds or, in some cases, by detaching suckers from the base of old plants. Garden varieties, on the other hand, are usually increased by grafting upon stocks of the common Lilac or by layering. At one time the habit prevailed of grafting varieties upon stocks of the Oval-leaved Privet, but it was never a satisfactory method, as such plants were short-lived, though free-flowering. Grafting, however, is not a commendable means of increase, whichever stock is used, for grafted plants are very prone to produce suckers, which, if not removed as soon as they appear, soon affect the well-being of the scions. Plants raised from layers are always to be preferred, and purchasers would do well to insist upon such.

Pruning is a rather important operation in connection with Lilac culture, and the failure of plants to bloom well may often be traced either to lack of pruning or lack of nourishment at the roots. In the first place, the bases of the plants must be kept free from suckers. Then weak shoots should be removed from the insides of the bushes, and here and there the weaker outer shoots must be thinned out. The object of all this pruning is to induce the plants to concentrate all their vigour upon the production of a limited amount of strong young wood. Plants which have outgrown their positions or have become taller than is desirable may be cut back into quite old wood. This may be done as soon as the flowers fade, or, if the owner does not mind losing a year's flowers, the pruning may be carried out in March. When pruning is accomplished at this

early date, the longest possible growing season is obtained. Lilacs which are to be used for forcing are grown specially for that purpose, and the shape of the plants is usually sacrificed in favour of flower-producing wood. All worthless shoots are removed on several occasions during the summer, and such shoots are never allowed to grow more than 3 inches or 4 inches long, the object being to concentrate all the energy into the building up of the wood which is most likely to produce flower-buds. Towards the end of August each plant is chopped round with a spade, and the ground is opened a little by working the spade backwards and forwards. This operation assists materially in the ripening

process. As a rule, from two to three years are allowed to elapse between the times when various plants are forced.

Selection of Varieties.—The garden Lilacs of the present day are very numerous, and present a considerable range of colouring, while many have double flowers. They have been derived from two species, *Syringa vulgaris* and *S. persica*. The former is the commonest and most vigorous kind. It is well known as a bush or sometimes as a small tree 15 feet to 20 feet high. A native of Eastern Europe, it is said to have been introduced in 1597. The second species, *S. persica*, commonly called the Persian Lilac, is another very old garden plant, for it was introduced from Persia about 1640. It is, however, less frequently seen than the other kind, although it is an excellent shrub for small gardens, for it rarely grows more than 3 feet or 4 feet high, and bears elegant panicles of lilac, very fragrant blossoms with the greatest freedom. *S. chinensis*, sometimes called the Rouen Lilac, is a hybrid between the two species referred to above. Growing 12 feet to 15 feet high, it forms a shapely bush and blooms very freely. Of the many garden varieties of Lilac, the following will be found to be a good selection:

Single-Flowered Varieties.—Alba, alba grandiflora, Frau Bertha Damman, Marie Legraye and noisettiana, white. Marie Legraye is shown in the accompanying coloured plate. Charles X., rosy purple; Congo, large, red; Géant des Batailles, dark red; La Ville de Troyes, purplish red; Mme. Kreuter, rose; Philemon, red; Princess Marie, lilac; and Souvenir de L. Späth, dark red. The last named is also shown in the coloured plate.

Double-Flowered Varieties.—Alphonse Lavallée, bluish; Doyen Keteleer, rose; Dr. Masters, lilac; Le Gaulois, red; Mme. Abel Chatenay, white; Mme. Lemoine, white; Michael Buchner, lilac; President Carnot, lilac; and Sénateur Volland, reddish lilac.

In addition to the garden Lilacs and their parents, however, there are others which deserve attention. Thus we have the very handsome *S. villosa*, a Chinese species which blooms three weeks later than the common sorts. It grows into a very large bush and bears immense heads of reddish lilac flowers, which, unfortunately, are not very fragrant. Then there is the large-growing *S. Emodi*, a handsome, vigorous bush, which bears creamy white blossoms during late June or early July. *S. japonica*, again, is another handsome kind, although it ought to have a little more sun than we have in this country to do itself justice. A tree in Japan, it forms a bush here. The cream-coloured flowers are borne in large, elegant panicles in July. *S. pekinensis*, from the mountains of Northern China, is another tree form which bears large heads of cream-coloured flowers, while the new white-flowered, pinnate-leaved *S. pinnata* from China is an exceedingly interesting shrub. The Transylvanian *S. Josikæa*, however, is scarcely worth planting,

except in very favourable places, for it is almost invariably seriously injured by spring frosts. D.

THE BLUE SIBERIAN COLUMBINE.

ONE of the first *Aquilegias* to flower, the Blue Siberian Columbine, *A. glandulosa*, is also one of the most dainty and graceful in habit. A foot or rather more in height, the blue and white flowers are singularly attractive, both in the rock garden and flower borders. For the alpine-house

AQUILEGIA GLANDULOSA OR THE BLUE SIBERIAN COLUMBINE.

the Blue Siberian Columbine is a delightful subject in pots or pans. Seeds form a ready means of increase, and the tufts when they consist of several crowns may be divided, August and September being a good time. Flowering early in the season, it is worth while planting this Columbine in a position facing south-west or west, with the idea of affording the slender flower-buds and blooms protection from the morning sun when in a frozen state, the result of a late spring frost. *A. glandulosa* delights in a moist, gritty soil of sandy loam and leaf-mould.

THE DAFFODIL IN AUSTRALIA AND NEW ZEALAND.

(Continued from page 401.)

Shows.—These in New Zealand were the surprise packet *par excellence*. I have not been able to trace more than four by name in Australia—Sydney, Geelong, Melbourne and Ballarat. But there are others, for one of my correspondents says there are “three principal ones,” mentioning the last three named. I hope if these notes meet the eye of any of the secretaries or others who can send me information and schedules of these unknown exhibitions that they will kindly do so, and thus confer a favour on THE GARDEN, the Royal Horticultural Society’s “Daffodil Year Book,” myself, and all whom my words reach. Knowledge of each other’s doings and mutual interest in one another are good things in themselves. We know where we are better then; we are not so apt to call our geese swans; we live and learn. As a Daffodil man I want to do what little I can to bring Daffodil people together, even if it is only by reading about one another’s doings. Not that it need stop there, for I hope that I may be sometimes sowing seed which will bring about a more personal connection.

Beginning with the most northern, the New South Wales Show, this is fortunate in having as its hon. secretary Mr. H. H. B. Bradley of Margaret Street, Sydney. There is no doubt it is the most important one in the province. As long ago as 1909 it gave an award of merit to a bunch-flowered variety, *Danæ*, raised by Mr. Bradley. Since then five more varieties have had either this or the higher first-class certificate given them, notwithstanding 1911 and 1912 being fallow years. The other shows are all Victorian. Although perhaps Melbourne, as the metropolitan show of the province, is theoretically the principal one, I am told that practically Ballarat is the best, as the date on which it is held is the most generally suitable. At the 1913 show Mr. Leonard Buckland of Keyham, Camperdown, won the big forty-eight class. Half those he staged were his own seedlings, and among the others he had Macebearer, Robespierre, Empire, Bernardino, Lord Kitchener, Fleetwing, Victory, Tudor, Florence Pearson, Kittiwake, Lemon Queen, Noble and Armeline. The

best flowers in their respective sections were: Yellow trumpet, Lord Roberts; bicolor, Weardale; white, Icicle (a seedling of Mr. Buckland’s); incomparabilis, Bernardino; Barrii, a seedling of Mr. Buckland’s; Leedsii, White King (a seedling of Mr. D. V. West’s), beating Empire; and Poet, Horace. If this is a fair sample of the best Victorian show, it is obvious that a winner there would have a “look in” at either London or Birmingham.

Now let me open the surprise packet. Twenty-one names dropped out. I was taken aback. I had no idea that New Zealand had so many

and I do not suppose I have every one that there are on my list. From Auckland in the north to Dunedin in the south must be getting on for a thousand miles; hence the show season is a long one. Last year it extended from August 28 (Auckland) to October 8 at Lawrence. The most important shows are probably (to judge by the schedules) those of Auckland and Hutt in the North, and those of Canterbury, Dunedin and Oamaru in the South Island. I have not seen a Lawrence schedule; but as I am told that the climate down there is particularly good for colour, and that the Daffodil is a specially honoured inhabitant of the Lawrencean gardens, I expect it will be a pretty good one. The Canterbury Society (headquarters, Christchurch) has a special Narcissus committee, with Mr. A. E. Lowe, head-gardener at Otahuna, Tai Tapu, as secretary; while both Auckland and Dunedin have certificate committees which perform similar but more general functions. The scheme of the New Zealand schedules is usually on the same lines as our own, collections, types, single blooms and seedlings all having classes assigned them. Two little things that I chanced to notice in going over the schedules are of interest. In the Dunedin Report, 1913-14, I read: "There is evidence of increased interest in the Narcissus Competition owing, no doubt, to the adoption of the classification of the Royal Horticultural Society." The other is, I imagine, the judge's pencil note against Class 1 at Auckland. Part of the "conditions" reads: "Forty distinct varieties, of which thirty kinds must be represented by at least three blooms, while not more than seven blooms may be shown of any one kind." And this is the remark by the side: "Committee should see to compliance with the mechanical points." I shake hands with the writer, be he judge or layman. Do I not know the time it takes, and, far worse, the bewildering effect it has when there is too much of it!

The number of the shows was only part of the surprise, although, as already stated, I do not suppose that I have every one on my list. Mr. Grindrod of Auckland whose name is known to the readers of *THE GARDEN*, divides shows in the North Island into two classes (1) *bona-fide* horticultural and (2) "Daffodil at homes," run by churches as attractive side shows to bazaars or as parish functions. One of the best is that of St. Mark's, Remuera, where the Vicar, the Rev. W. Beatty, is a good, practical Daffodil man. I have the schedules of two of these church-run shows before me—St. Luke's (Anglican), Rotorua, which is a small one, and the Cambridge Daffodil Society, run under the auspices of the Cambridge Presbyterian Church, which is a large one. Another example is Johnsonville (Wellington) Bulb Show and Sale, which was held on September 10 and 11, 1913, in "aid of the Methodist Parsonage." Eighteen out of forty-one classes were for Daffodils. In five others they might be used if competitors wished. I notice one was for a decorated mantelpiece. I think it a capital

idea, and one that societies at home might adopt with some practical advantage. All this is food for thought, and possibly imitation.

Dealings.—From the list of some of the flowers of Mr. Buckland's forty-eight at Ballarat last year it will be seen that some of our best things have gone to Australia. Should this possession of the best be thought to be an isolated case, a perusal of Messrs. W. H. Higgins' list at once puts any doubts at rest. *Croesus*, *Challenger*, *Empire*, *Furnace*, *Michael*, *Miss Willmott*, *Robespierre*, *Sea Horse*, *Sir Horace Plunkett* and *Tamerlane* are all there, with many more of lesser value. Then take Messrs. Arthur Yates and Co.'s Auckland catalogue. Twenty-nine of Professor A. W. P. Thomas' seedlings are offered at prices ranging from 2s. to 30s. each. Clearly there is a good trade done in expensive varieties in these distant parts of our Empire. Ah! but the responsibility of those who write and comment on the latest

I appreciate all they have done very much, even if I do not mention them separately and individually by name.

JOSEPH JACOB.

CALOCHORTUS MAWEANUS.

THESE delightful and attractive bulbous plants, belonging to the Order Liliaceæ and sometimes spoken of as Star Tulips and Mariposa Lilies, do not seem to be grown as much as their beauty justifies. Our climate does not seem to be ideal for their cultivation, though with perfectly drained, light, porous soil, protection from heavy winter rains and thorough ripening of the bulbs after flowering, either by lifting or protecting them by a glass-light, some amount of success may be obtained. Probably the climatic conditions prevailing on the western side of North America, where these plants hail from, are much more kindly

CALOCHORTUS MAWEANUS, AN ATTRACTIVE STAR TULIP OR MARIPOSA LILY.

and choicest blooms that we see in England! Such an one is verily between the devil and the deep blue sea. Editorial requirements make selection and criticism imperative, and *then* the luckless wight gets this: "I spent two or three hours yesterday to see what you said about Robespierre, as I remembered you had said something about it. If it is not a good one I will blame you!" That same person disclosed his order. Quite a nice little one: *Bert Sands*, *Brilliance*, *Croesus*, *Empire*, *Much-the-Miller*, *Royal Sovereign*, *Tudor*, *Bull Dog*, *Countess of Stamford*, *Diogenes*, *Gannet*, *Grootvorst*, *Harmony*, *Onslaught*, *Target* and *White Star*. I think he can take care of himself!

And now I must stop, and my last paragraph must be a word of very hearty thanks to all my kind correspondents, male and female, Australian and New Zealandian, who have honoured me with letters and photographs and catalogues

and less sodden during the resting season than in our own cloudy land. While early planting is the keynote to success with many bulbous plants, it is much more necessary with the *Calochorti*, and since a very free soil comparatively dry through the winter is required, yet ample water during the growing season, the moraine should prove a likely habitat for them in our gardens. Having had considerable success with several of the choicer species of dwarf *Narcissi* in that position, I propose trying the Star Tulips there, and hope to report progress at a later date. One of the features common to several of the genus is the way in which the inner surface of the petals is more or less heavily coated with filament-like hairs. By virtue of their showy flowers and exceptional colours, the Star Tulips or Mariposa Lilies never fail to attract attention when one is fortunate enough to have them in flower.

REGINALD A. MARRY.

DECIDUOUS FLOWERING SHRUBS DURING 1914.

THE season of 1914 will long be remembered as an ideal one for these ornamental garden subjects. Never have I known them to flower so well. Doubtless the sunny autumn of last year and the heavy rains of March had much to do with it. The Ribes and Prunuses, which were among the earliest to flower, were equally as productive as the Buddleias, which are now expanding their long sprays of mauve-coloured blossoms. Speaking of Buddleias, one cannot recommend too highly the variety *B. magnifica gigantea*. It is a charming subject for a large bed, particularly if edged with *Ceanothus Gloire de Versailles*. They both flower at a time when most of our other flowering shrubs are over. Both require hard pruning in the springtime, cutting the young wood back to within two or three eyes of the base.

The Philadelphuses, of which Mont Blanc is about the best, have well repaid for the amount of

and as far through if allowed room to grow. Lilacs and Viburnums have never flowered better. We have a large bed of Lilac here in variety, planted 9 feet apart, and the effect when in flower is most pleasing, the ground between the plants being used for *Erigeron speciosum* and *Aster acris*, so planted that we have a display throughout the whole of the summer months.

Almonds growing in exposed positions flowered well and long, and are now carrying heavy crops of fruit. Like the Peach, they suffered badly from the blister at the time the winds were so cold during April. This, after all, is only a reminder that they hail from a warmer country than our own. The Cydonias, of which there are now so many excellent kinds, were a sight not soon to be forgotten. The late Mr. Milner was particularly fond of planting these together on mounds 10 feet or 12 feet apart, and only those who see the effects of his work, where the plants have been allowed to grow at will, can realise what a charming effect is now produced. We have one such mound here, made twenty years or more ago, the base being now planted thickly

AN AUSTRIAN HAREBELL (*CAMPANULA PULLA*) IN THE ROCK GARDEN.

space they occupy. By growing a collection of these in various aspects it is not at all difficult to have them in flower for many weeks. As is well known, they are charming subjects for cutting for large vases. They will stand any amount of pruning after the flowering is over, so that all the energy available is directed to the young growths, which usually appear in June and July.

We have now a host of *Spiræas* to suit almost all positions and seasons. *S. confusa* is particularly good in May. The flowers are white, and are produced on the previous season's growths, which suggests that these, too, require pruning after flowering is over. The plants have a particularly decorative effect, even when not in flower, owing to the light and feathery manner of their growth. *S. Anthony Waterer*, a dwarf crimson-flowered variety, makes a very charming and peaceful picture when planted with *Acer atropurpurea*. It is also an excellent shrub for a rock garden, and flowers in July. *S. arifolia* is more suitable for brightening up heavy shrubberies, and reaches a height of 12 feet or more

with Darwin and Cottage Tulips, which flower at the same time as the *Pyrus*.

Shendish Gardens, Herts. GEORGE BURROWS.

CAMPANULA PULLA.

A NATIVE of the Austrian Alps, this species is one of the daintiest of the dwarf Harebells. It is a very old garden plant, having been first introduced in 1779. Growing 4 inches to 6 inches in height, the nodding, bell-like blossoms are at their best during June. The colour is a pleasing shade of purple or violaceous blue. Having chosen a pocket in the rock garden for this Austrian Harebell, make up a gritty, stony compost containing sandy loam, peat and leaf-mould. Increase by division is best done in the spring, at which time the young shoots may also be inserted as cuttings, when they will root freely in sandy soil. *C. pulla* thrives in the crevices between stones, and should be included among the Campanulas grown on the wall garden. The comparatively large bells seem almost too heavy for the slender stalks to support.

WORK AMONG GRAPE VINES.

SO far the weather this year has been quite favourable for the Vines, and the bunches of Grapes look very promising. The weather may not be of a settled nature during the months of August and September, and if this proves to be the case, the cultivator must very carefully watch every bunch and do all he can to finish the colouring of the berries so that they will not only look well, but keep well if necessary.

What to Do in Bright Weather.—In houses where the berries are colouring, it will be advisable to ventilate freely both night and day, but, of course, more so during the daytime than at night. At this season the air becomes very cool towards evening, and from midnight to sunrise it is often very chilly. Cultivators often fail to realise this, and consequently they leave the ventilators open too wide the last thing at night, and mildew then spreads rapidly, not only on the leaves, but on the berries too. It is not necessary to use fire-heat. If the front ventilators are almost closed at sunset and the top ones are left 3 inches to 6 inches wide on the side opposite to that from which the wind blows, there will be no cold current of air passing through the interior of the structure. In these circumstances the berries of black Grapes will colour in twenty-five days.

What to Do in Cold, Dull Weather.—I now refer to weather that is generally adverse to the proper ripening of Grapes without artificial aid. The amount of ventilation must be reduced both night and day, and on dull days the pipes must be warmed as well as at night. There is always a danger of moisture condensing on the berries, and if this happens repeatedly and the sun shines on them suddenly, even for a very brief time, while they are in this condition, the berries will soon decay. Although the ventilators may be almost closed, warm pipes will have the effect of preventing the condensation of moisture, as the air will be quite buoyant. Under these conditions, black Grapes will take thirty days to finish colouring satisfactorily.

The Proper Quantity of Foliage to Retain.

It is a mistake to allow a lot of lateral growth at this season, as the young foliage prevents air and light reaching the main leaves and basal buds on the bunch-bearing shoots. All small side shoots must be cut off regularly, so as to well expose the main leaves. With regard to the bunches of white Grapes, it is absolutely essential to success that only main leaves be retained, and these must be put to one side a little so as to expose the bunches if the latter are to be well coloured—a deep amber.

The conditions suitable to the good colouring and maturing of the Grapes are equally suitable to the keeping of the berries. In spells of dull, damp weather the cultivator should closely examine every bunch and cut out forthwith any decaying berries. The bad berries are generally found near the centre of the bunch, and if one is left there for a few days, the greater portion of the bunch will soon decay. When the bunches are cut from the Vines, give the latter a thorough syringing, and ventilate more freely night and day. Keep the soil of the border in a nice, moist condition, not only while the bunches remain on the Vines, but throughout the winter.

AVON.

GARDENING FOR BEGINNERS.

TREATMENT OF CHRYSANTHEMUMS IN LATE AUGUST.

THE majority of the buds are "taken" late in August, because they include those of the incurved section as well as late first crowns and second crowns of the Japanese section and the earliest terminal buds. At this stage the plants grow very freely, and the inexperienced cultivator must be careful regarding watering and

strength of the plant is concentrated in its development after the side shoots are removed.

Terminal Buds.—Fig. B shows how these buds are dealt with. There is really no difference in the method of "taking" these to that of "taking" crown buds. In the latter case shoots are broken off; in the former, buds. The bud to "take" or retain is the central one, as shown at No. 1. All the others, Nos. 2, 2, with dark lines drawn across their small stems, are removed; then the stem of the plant is free, as shown at Nos. 3, 3. No. 4 depicts the central bud swelling freely. Terminal buds of naturally late-flowering varieties are useless for all practical purposes, as they are too thin, somewhat resembling a bloom of a single-flowered variety without possessing the latter's good points. Terminal buds on some plants of the naturally early flowering varieties, especially those of some of the incurved

A.—"TAKING" A CROWN BUD.

feeding. If the weather is dull and cool, it would be unwise to give much liquid manure, as the soil does not dry quickly. Clear water should be applied when necessary, as the pots are full of roots and the soil in which they are growing and increasing must not be allowed to become at all dry. Some chemical manures may be given according to the directions supplied with them. In this way during wet weather, when it is inadvisable to apply liquid too frequently, much valuable aid to growth can be given and without causing a too sappy condition of the stems and leaves. Of course, the strength of the plants must be maintained, so that they will be well able to support the buds as the latter form.

"Taking" Buds.—Late first crown and second crown buds must be taken as shown in Fig. A. The bud, No. 1, must be just free of all side shoots when the latter, Nos. 2, 2, 2, are cut or broken off. If they are picked out with the point of a knife, as is often the case, there is a danger of the buds being injured, and the slightest damage done to them while in such a small state will spoil them for exhibition purposes or for home use in the conservatory and dwelling-house. Nos. 3, 3 show the stem of the plant cleared of all side shoots. No. 4 represents the crown bud swelling freely, as practically the whole

B.—"TAKING" A TERMINAL BUD.

ones, generally develop into deep, refined flowers of rich colour.

Top - Dressing.—Too frequently the inexperienced cultivator fills the pots too full at the final potting, and then there is not much space left for watering and top-dressing. In such a case, strips of tin or zinc may be placed round the rims of the pots, as shown in Fig. C. The soil, almost level with the rim of the pot after the first top-dressing material has been put on, as shown at No. 1, prevents further additions to it; but if the zinc strip, denoted by the arrow, is put in position, more soil may be added, and feeding and watering done readily enough afterwards. Even strips of fibrous turf in which the grass has died may be used with considerable success instead of zinc.

G. G.

NOTES ON ANNUALS.

Staking and Tying.—My own practice in growing such thin-stemmed subjects as *Gypsophila elegans* in clumps or rows is to place a few stakes around and in the bed, binding the tying material first to the outside stakes and then across the centre a few times. This method divides up the clump into small sections, and is found to be efficacious, not only in keeping the growths upright through all weathers, but also to be beneficial to the general welfare of the plants. Placed early, the tying material and stakes are soon hidden from view by the flowering stems. Other annuals, such as the Shirley Poppy and *Coreopsis* type, do best individually staked and allowed ample room to develop. A point often too seriously worried over is

The Question of Watering (at least this is my own considered judgment, bred of experience). I confess to having a much greater partiality for, and faith in, the Dutch hoe than in the watering-can, and my ground is decidedly on the light side. In regard to this question of water, my usual rule is to "let well alone," meaning by this that so long as no signs manifest themselves that things are wrong, I act on the natural assumption that they are right, and the frequent use of the hoe makes for the latter state.

For cutting the following are found very useful: Shirley Poppies.—Cut young and open in water. African Marigold.—Prince of Orange. Stocks.—Ten-week. *Nigella damascena*.—Miss Jekyll. Annual Chrysanthemum.—Eastern Star. Zinnia.—Double varieties. Sweet Sultan.—Giant. Cosmea.—Early flowering strain. Godetia.—Double Rose. Sweet Scabious.—Treated as an annual and shown as such. Salpiglossis.—Grandiflora. Clarkia.—Elegans. *Coreopsis*.—Drummondii.

B. W. LEWIS.

C.—THE METHOD OF TOP-DRESSING.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Fig Trees in Pots which are intended to produce ripe fruits in April must be placed in the open air in order to harden and prepare the trees for early forcing. If possible, the pots should be half plunged in ashes as a protection to the roots from strong sun, for although no great quantity of moisture will be necessary, the roots must not be allowed to suffer from want of water, or the foliage may drop before the growth is quite matured, and the prospect of a successful crop will be reduced in consequence.

Melons.—The latest-planted Melons should be making good progress, and the shoots well up the trellis. Secure a full crop as soon as possible, and endeavour to grow the plants without a check. Keep the side shoots stopped, and never allow the plants to become overcrowded or dry at the roots.

Tomato Plants for winter supplies must not be allowed to become stunted before their final potting. Nine-inch pots will be large enough, and the soil may consist of two-thirds turfy loam and the remainder of decayed horse-manure. This may be prepared a few days previous to use, and should be made tight about the roots. If damp, sunless weather sets in, these plants ought to be placed in some cool, well-ventilated structure and fully exposed to the sun. Another sowing may be made now to produce a few trusses of fruits in the beginning of next year.

Plants Under Glass.

Pelargoniums.—The majority of these plants should be cut back to within a few eyes of the previous season's growth. The pots may then be placed on their sides and allowed to remain until growth commences, when the plants may be repotted and placed in a well-ventilated frame on a bed of ashes. Water sparingly and keep the ventilators open night and day. Cuttings may be inserted in sandy soil and placed in a cold frame until rooted, when they should be potted into 3-inch pots and grown in cool quarters quite close to the glass.

Cyclamen which are growing in cold frames should be freely ventilated, removing the lights at times while the weather is suitable; but the plants must not be subjected to heavy or continual rain. Green fly and thrip are sometimes troublesome, and must be kept in check by fumigating. Young plants should be potted on as it becomes necessary, and carefully watered until the roots have reached the edge of the new soil.

The Flower Garden.

Antirrhinums.—If the best varieties of these are obtained, they are certainly among the most satisfactory bedding plants, and may be had in almost any colour ranging from white to very dark red. For early summer bedding the seeds should be sown now and the plants grown in nursery beds during the winter, but for a later display, from July to October, the seeds may be sown in January or February and the plants put out in May. To ensure a continual display through the autumn, the flower-spikes must be removed as soon as the blooms have fallen. Water will also be necessary during dry weather.

Pansies for Spring Bedding.—These should now be ready for transplanting into nursery beds, where they may remain until the beginning of October. Keep them well supplied with water, and stir the soil between them with a small Dutch hoe. Aubrietias also ought to be transplanted now and treated in the same way. Protection from strong sun will be necessary until the plants make fresh roots. All spring bedding plants should be pricked out with as little delay as possible. Allow a good space between the plants in order to keep them stocky.

The Hardy Fruit Garden.

Raspberries.—Now that the crop is over, the old fruiting stems should be removed and those for next season's crop secured to the wires, as with autumn winds, many of the strongest shoots may be broken.

Autumn-Fruiting Raspberries should now be in a forward state, and will benefit by a good soaking of water at the roots, which will help to

prolong the supply as well as increase the size of the fruits.

Autumn-Fruiting Strawberries will also benefit by careful and frequent watering. If the plantations are in good condition, a supply will be available well into October, providing the weather is favourable. For this purpose we find St. Antoine de Padoue the best variety. The runners are secured in the autumn, wintered in a cold frame, and planted on a well-prepared border about the last week in March.

The Kitchen Garden.

Celery.—The early plantations of Celery should now be growing freely, and will require a good supply of moisture at the roots. There must be no mistake about this matter, especially previous to earthing up the plants. The early plants should be earthed up as soon as possible, and while this is being accomplished, care must be taken to keep the hearts of the plants quite free from soil.

Winter Spinach.—A good sowing of Prickly Spinach should be made about the third week in August for use during the winter and spring. If the ground is dry at the time of sowing, the drills may be watered a few hours previous to sowing the seed. When the crop is through the surface, a careful watch should be kept for slugs, which are troublesome during the autumn. Frequent dustings of soot and wood-ashes may be given with advantage.

Endive.—The Batavian Endive makes an excellent salad during the winter, when good Lettuces are scarce. This should be sown now, transplanting the seedlings to a protected border as soon as large enough to handle.

Lettuce should also be sown now for use during the early winter. Another sowing may be made two days later. Hardy White Cos, Maximum and Stanstead Park are good varieties for early winter use.

Radishes may still be sown. A spent hot-bed would suit them well, as a quick, succulent growth is necessary. They will benefit by plenty of water at the roots.

Mustard and Cress.—Make weekly sowings in a cool, shady frame, so that no break in the supply may take place.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Mushrooms.—Continue to collect manure to form another bed in the Mushroom-house, and spread it out in small ridges in an open shed to dry, as previously advised. It is not necessary to waste much time in separating the straw, as only the longest need be collected. Turn the manure frequently to prevent it becoming overheated, in which case much of the ammonia is lost. When sufficiently sweetened, it should be rammed into beds as firm as possible, after which insert a thermometer, and spawn when the heat declines to anything from 85° to 90°.

French Beans.—A sowing may now be made in frames or pits for a late supply, and, to encourage a sturdy growth, the lights should be kept off until they are actually required as a protection against early frosts. It will, perhaps, be as well to allow more than the usual distance between the rows, and also the plants, as it is important that each plant should have ample light and air for this late crop. As to varieties, there is not much to choose from, but possibly Canadian Wonder is as good as any for this sowing.

Radishes.—As the earlier sowings are usually made in odd corners or between the rows of other small-growing crops, those sown after this date should be made in a border not too much exposed to the sun. It is also essential that they be thinned when quite young, otherwise the result will be too much top growth and very poor roots.

The Flower Garden.

Hollyhocks.—The rust fungus that attacks these stately plants is this season more in evidence than ever, with the result that the plants, instead of being ornaments, are extremely unsightly. I find those treated as annuals, or at least biennials, are not nearly so liable to attacks from this pest as

older plants; indeed, among several hundred plants treated in this way here, there is scarcely any trace of it at all. Collect seeds from the earliest-ripened capsules and sow as soon as they are sufficiently ripened, afterwards pricking out the seedlings into a warm border.

Sweet Peas.—In many cases Sweet Peas are inclined to be somewhat stunted in growth, and consequently seed-pods are forming in greater numbers than usual. These must be regularly removed; and, indeed, if time permitted, it would be advisable to reduce the flower-buds considerably to encourage the plants to make growth. As already advised, continue to feed the plants with liquid manure or a small sprinkling of Clay's Fertilizer.

Campanula pyramidalis.—This favourite biennial, usually grown in a cool greenhouse, is, I find, perfectly hardy, as during the past two years it has produced splendid spikes, and the colour, if anything, is slightly more pronounced. Plants by this date will be sufficiently advanced in pots or boxes, and may be planted out in a sheltered spot. Should any doubt exist as to their hardiness, a few plants may be put out as an experiment.

Plants Under Glass.

Campanula isophylla.—This lovely trailing plant, so useful for hanging over the front of the stage or from hanging baskets, will now have passed out of flower. To replace the stock of older plants, a batch of cuttings should be secured at once; they root freely in a cold frame where shade can be afforded. It can, of course, be raised from seed; but, generally speaking, cuttings make the better plants.

Schizanthus.—To secure plants for spring flowering, seed may be sown now, and for a succession sow again in a month. As almost every seed will germinate, it will be necessary to sow thinly. Three or four seeds in a small pot will be ample, afterwards thinning the seedlings to one in each pot. From the very outset they must have cool treatment, and be kept sufficiently close to the glass to prevent them becoming spindly.

Roman Hyacinths.—For early forcing, a number of bulbs should be potted up without delay, and, for this early supply, pots should be used in preference to boxes, as being more easily handled. After potting, give them a soaking of water, and plunge the pots in ashes to the depth of 3 inches or 4 inches.

Salvia Glory of Zurich.—Plants intended for autumn flowering will now be well rooted in their flowering pots, and may be assisted with liquid manure very frequently from now onwards.

The Hardy Fruit Garden.

Summer Pruning.—No time should be lost in completing this important work, as, if delayed longer, the shoots absorb a great deal of the sap that should go to swell the fruits and build up the fruit-buds for another year. In going over the trees, opportunity should be taken to remove all deformed fruits, which would only have to be thrown away in any case.

Apricots.—Now that the fruits will be ripening, a sharp look-out should be kept for earwigs, which are most destructive to the ripe fruits. Perhaps the best way to trap the pests is with small pots filled with hay and placed conveniently among the branches. These must be examined every other day, and the insects destroyed.

Fruits Under Glass.

Figs.—Trees carrying heavy crops of fruit must be kept growing steadily, and, if any doubt exists as to their being able to ripen the crop, it will be advisable to thin the fruits considerably. At the same time, thin out the growths where they are at all crowded, and apply liquid manure at frequent intervals. Every means must be taken to keep the foliage clean by syringing and damping down the paths and walls several times a day.

Early Grapes.—Where most of the bunches have been cut, those remaining may be taken to the fruit room and bottled; this is all the more necessary if the foliage has become infested with red spider. Throw the house open and apply the syringe vigorously, as it is important to the proper ripening of the rods that the foliage should remain as long as possible on the Vines.

NOTES ON GERMINATION.

July 27. All the lots dressed with residue are strongest; ore, control, farmyard and Clay's much alike. Guano latest.

With the Mignonette and Dimorphotheca the difference was very marked, the plants in Nos. 2, 3 and 4 being very good, though those in No. 4, *i.e.*, treated with a mixture of Clay's Fertilizer and oxide of uranium, were the best. This was also the case, though less pronounced, in the Calendulas and African Marigolds. It will therefore be seen that the radio-active ore, residue and black oxide of uranium do have a beneficial growth on some plants and under certain conditions, but there is, evidently, a good deal of further research work needed before definite conclusions can be arrived at. Messrs. Sutton have rendered a public service in what they have done, and we feel sure they will continue the experiments with a view to obtaining more definite data on what will eventually prove a very important item in the cultivation of crops.

				Loz.	of Area.

(1	"	"	48	"	"	(B) Ore placed at bottom of box	9	1 0	1 9	8th (equal)			

Flowering annuals, however, treated with black oxide of uranium gave different results. Mignonette, *Dimorphotheca* hybrids, Calendulas, and African Marigolds were tested. The oxide of uranium was used as follows:

1. Control (plain soil only).
2. Black oxide of uranium (one part in 2,000 parts of soil).
3. Clay's Fertilizer (at 8oz. to 40lb. of soil).

Bacterised Peat Experiments.—On the same occasion we were much interested in some experiments that Messrs. Sutton have conducted with Professor Bottomley's bacterised peat, referred to in our issue of November 1, 1913. These were in four series, viz.: 1, large plots in open ground; 2, plants growing in pots in pit sand only; 3, Lettuces and Dwarf Beans in soil; 4, Radishes and Lettuces in soil in boxes. In Series 1 the plots were as follow: A, control, no recent manure; B, top-dressed with bacterised peat at the rate of 8oz. per square yard; C, farmyard manure dug in at the rate of 20 tons per acre, and, after the plants were up, a top-dressing of bacterised peat, 8oz. per square yard; D, top-dressed with ordinary peat moss treated with sulphate of ammonia; E, farmyard manure as in Plot C, and, after plants were up, a top-dressing of ordinary peat treated with sulphate of ammonia, 8oz. per square yard. With Peas on these plots the following results were obtained: Plot A, 3lb.; B, 3lb. 2oz.; C, 3lb. 6oz.; D, 3lb. 1oz.; E, 2lb. 10oz. It will thus be seen that the farmyard manure, followed with the top-dressing of bacterised peat, gave the best results, *i.e.*, 4oz. more than B, treated only with a top-dressing of bacterised peat, followed by D, A and E in the order named. With Potatoes Stirling Castle, a midseason variety, the results were as follow: Plot A, 63½lb.; B, 76½lb.; C, 79½lb.; D, 66lb.; E, 82½lb. This difference

in the results of Peas and Potatoes is very interesting. When Professor Bottomley lectured to members of the Horticultural Club (see *THE GARDEN* for November 1, 1913, page 547), it was pointed out that the bacterised peat induced considerable root growth; but in Messrs. Sutton's experiments this has not been the case, especially with the Peas. In the pots and boxes of Radishes, Lettuces and Peas, where artificial watering was resorted to, the bacterised peat gave good results, and it would therefore appear to be of the most value as a manure during a wet season.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

NIEREMBERGIA FLOWERS INJURED (*Miss W.*).—We are unable to say what is attacking the Nierembergia. Probably the damage is done at night, and the culprit might be caught in the act by searching with the aid of a lantern; but possibly birds are to blame. There was no trace of insects or fungus in the specimen sent.

TREATMENT OF LILIES (*Alford*).—Withered flowers may always be removed at once, but the stems of the Lilies should not be cut down, unless badly affected by disease, till they are fully matured. Where diseased, it is better to cut them down and burn them as soon as flowering is completed.

BEDDING ARRANGEMENTS (*E. Sheppard*).—With so much white spar about the beds you should work for contrasting colours, and for the round beds we suggest Begonias or Violas, the former in crimson, orange, scarlet and pink; the latter in blue, royal purple, rich yellow and bronze; or you might mix these in the beds by planting both rather thinly. For the half-circular beds, No. 2, try Verbenas (pegged down) in pink, scarlet and purple alternately. For No. 3, Heliotrope President Garfield, pegged down, would be good, with masses of brilliant blue Lobelia for all the small beds marked No. 4. If there was not so much white spar about, white and pale yellow Violas and Begonias could have entered into the scheme, also Mesembryanthemum cordifolium variegatum, but these would appear sickly and ineffective in the circumstances.

KITCHEN GARDEN.

PEAS FOR INSPECTION (*J. H.*).—Late-sown Peas often suffer from drought, &c. We find no disease either of fungus or bacterial origin.

POTATOES WITH ROUGH SKINS (*Reader*).—The trouble from which the Potatoes are suffering is only skin deep. It is usually called "scab," and is very frequent on sandy soils. Steeping the seed tuber in formalin solution, a pint to thirty gallons of water, for two hours is occasionally a preventive; but, unfortunately, the fungus is also in the soil. Lime usually increases its effects.

PEAS NOT DOING WELL (*S. F. G.*).—The Peas must have done well up to the podding stage, as the haulm is strong. The trouble, no doubt, is at the roots. Have you examined the roots and base of the stems well and carefully for wireworm? It looks very much like the work of this destructive pest. Have the plants been very dry at the roots for some time? Peas will suddenly collapse from this cause, especially at the time of podding, when the strain on them is heavy. We have also seen the same result follow a too heavy application of patent manures.

EELWORM IN TOMATOES (*Novice*).—An attack of eelworm on Tomato roots is incurable. Turn out all the soil as soon as the plants are done, and either burn it or spread it on a pasture where there will be no chance of it being taken back again into the houses (or put into pots) for several years. Take care also that all the pots and crocks are thoroughly disinfected. Steam-heat or bake the soil in which you intend to grow Tomatoes next year. The spotting of the Tomato foliage is due to burning, probably arising from insufficient ventilation in the early morning.

TOMATOES DISEASED (*Dr. G.*).—Your plants are apparently suffering from the "sleepy" disease of the Tomato, which is caused by a fungus attacking the root and getting into and filling the vessels along which the water flows, checking the water supply to the foliage, with the result that the plant wilts and dies. The only thing to do—and even this, we fear, will not prove very satisfactory—is to earth up the plants, so as to induce fresh root formation from the stem. The best measure to pursue next year will be to sow the seed and grow the young plants in sterilised soil.

TOMATO FOR INSPECTION (*M.*).—The Tomato arrived all right, but not the leaf. The fruit sent is excellent, very fleshy and the flavour good; indeed, we could not wish for a better. The yellow colour at the stalk is only an indication that the variety has at some time been crossed with a golden variety. It is no detriment. Ventilate freely on warm, sunny mornings, and close the house up with sun-heat about 3 p.m. or 3.30 p.m., having previously syringed the borders,

floors and sides of the house, but not the plants themselves too much. On a heavy afternoon the temperature under this treatment will often rise to 80° or 85° Fahr. This, you will find, will move things on, and help the fruit to grow and ripen in a much shorter time. Of course, you must water with care, and if the plants are sickly, use clear water only, giving the border a slight dressing of lime and adding thereto a top-dressing of sweet maiden loam.

MISCELLANEOUS.

MOTH FOR IDENTIFICATION (*L. L.*).—The moth sent is the wood leopard moth; it is beautiful, but, unfortunately, a pest of fruit trees, especially of Apples and Pears, into the wood of which its larvæ bore and do considerable damage. It was illustrated in our issue for April 4.

PROPAGATING NURSERY STOCK (*B. Hartigan*).—We regret to say that we do not know of such a table as you suggest dealing with the propagation of nursery stock of all descriptions. If you procure text-books upon the different branches of horticulture, you will, however, find a good deal of what you require.

STERILISING SOIL (*R. M. L.*).—We think your method of sterilising the soil would serve your purpose well, but we should be inclined to use one-half per cent. formalin (a gallon of commercial 40 per cent. formalin to 200 gallons of water). We do not think it would be necessary to cover the ground with canvas, but the frames might be covered for three days and the soil afterwards left for three weeks to permit the formalin to evaporate.

INSECTS IN WATER (*O. R.*).—No doubt the insects present in the water are the larvæ of the gnats. Fish kept in the water will do much to keep down these insects (which, while they are harmless to the Water Lilies, are distinctly annoying to human beings), and will be better than putting on a thin covering of paraffin, which is perhaps the most deadly way of attacking gnats, but which is always attended with some danger of damage to the plants.

VARIOUS QUESTIONS (*N. M. M.*).—The Phlox is attacked by stem eelworms (see our reply to a correspondent recently on this pest). The Gooseberry is attacked by the fungus Botryosphaeria ribis, which fruits on the dead wood. All the affected branches should be cut out and burnt immediately, so as to check the spread of the disease at its onset. There is nothing to show to what the death of the Apples is due, for the shoots sent are quite healthy. The piece of root appears to have been wedged in between stones.

INSECTS IN COLD FRAME (*Linden Tree*).—The insects complained of must be hiding in the frame or underneath the pots, pans or boxes in which seeds are sown. A good plan will be to remove these receptacles from the frame and give it a good dressing, but particularly on the bottom, with unslaked lime. When the pots, pans or boxes are returned to their places, the lime will prevent the insects or slugs, if there are any, from making their way to the seedlings. If the pests are woodlice or earwigs, which may be answerable for a good deal of the mischief, they may be trapped by laying some small pots with a little dry moss in each in the frame, and examine them every morning, shaking the insects into a pail containing a little boiling water. Another plan particularly successful with woodlice is to take some Potatoes and cut them in halves. Then scoop out a part of the middle and lay the hollowed portions, concave side downwards, where the pests are most likely to congregate. They must be examined every morning. Another point we can recommend is to visit the frame when dark, and by the light of a candle or lamp you will probably find some of your enemies hard at work, when their destruction is an easy matter. If the sawdust is thoroughly burnt—that is to say, turned into ashes—it would be valuable for many garden purposes, more particularly if your soil is of a stiff, clayey nature. In that case a liberal dressing may be worked into the soil whenever it is being dug. For herbaceous borders, Roses, &c., a dressing may be applied during the autumn months and the surface of the soil occasionally worked over with the hoe. For potting soil a small proportion of ashes may be mixed with the ordinary compost.

CLAY SOILS (*B. V. Y.*).—These are usually difficult to deal with. Clay, however, is variable, and much will depend on Nature. As it happens to be badly weed-infested and has to be practically entirely made, you had better proceed by deep trenching and forking out all big weeds, such as Couch, Docks, Dandelions and the like. Gather these together with any brushwood and make a bonfire, the ashes from which would be valuable on the land. As you are taking in a portion of an orchard, you should have much wood to burn up after cutting down the trees. The best way to deal with such a soil would be to burn a portion of it into soft ballast, and, by incorporating this with the staple, you aerate, drain and lighten by a single action. Heavy lime dressings play a like part. It would assist matters if you plough off the rough herbage and burn that. We cannot say how long it would take to clear the ground; everything depends upon the nature of the weeds and the thoroughness of the work in cleaning the land. As you have no experience in such matters, you would do well to get expert advice at the start. For the formal Lily pool a supply of water under control would be best, and unless the clay is quite of a tenacious character and well puddled, cement had better be used. An overflow is always desirable. In both of the above much depends upon circumstances. Hardy plants for such a soil should include Peonies, Irises, Delphiniums, Spiræas, Kniphofias, Michaelmas Daisies, Heleniums, Phloxes, Campanulas,

Trollius, Chrysanthemums, Day Lilies and many more; but what would be exactly suited to the needs of the case would depend entirely upon the size of the borders. This also applies to the shrubs. When the borders are formed, or their size and position determined, write us again on these matters. Roses are usually at home in clay soils.

NAMES OF PLANTS.—*A. E. B.*—1, Rose Marie Pavie; 2, Rose Bettelstudent; 3, Rose Petite Marcelle; 4 and 5, garden varieties of Phlox, cannot match; 6, Colutea arborescens (Bladder Senna); 7, Melissa officinalis (Balm); 8, Philadelphus coronarius; 9, Polygonum cuspidatum; 10, specimen too incomplete for identification.—*H. H. G., Yorks.*—The Sweet Pea is of no value. The yellow Rose is much like Mme. Hector Leuilliot. It is a strong grower. If of dwarf habit, it may be Mme. Charles de Luze. The other variety is G. Nabonnand.—*J. C. W.*—1, Melilotus officinalis; 2, Lychnis coronaria; 3, Veronica longifolia; 4, Sempervivum montanum.—*W. Crook, Mancetter.*—1, Adiantum cuneatum; 2, A. gracillimum; 3, A. formosum.—*W. Banks.*—1, Festuca glauca; 2, cannot name without flowers, probably Ailanthus glandulosa; 3, Lathyrus latifolius albus; 4, L. rotundifolia; 5, Polygonum Bistorta; 6, Myosotis palustris sempervirens; 7, Veronica spicata variegata; 8, Linaria vulgaris; 9, Enothera fruticosa; 10, Geranium Endressii; 11, Antennaria dioica variety tomentosa; 12, Sedum rupestre; 13, S. spurium; 14, Stachys lanata; 15, Campanula pusilla alba.—*E. T. W.*—1, Eupatorium aromaticum; 2, Trautvetteria palmata.—*M., Stavanger.*—1, Too far advanced to say; 2, Mme. Audot; 3, Rosa alba.—*W. J. R.*—1, Probably a variety of Lælio-Cattleya bletchleyensis; 2 and 3, forms of Cattleya Mendelii; 4, Lælia xanthina.—*H. H. G., Yorks.*—It is impossible to name such scrappy specimens.—*Mrs. Sartorius.*—1, Cistus species; 2, Geranium species. The specimens were too scrappy for identification.—*J. B., N. Wales.*—Bocconia cordata.—*Torquay.*—Criminum species, probably C. longifolium.—*Miss J. K., Suffolk.*—Criminum species.

SOCIETIES.

HIGHCLIFFE GARDENERS' ANNUAL OUTING.

ON Wednesday, July 29, the members of this society had their annual outing, visiting Pylewell Park, the residence of W. Ingham Whitaker, Esq., and Elmers Court, the residence of Hugh Whitaker, Esq., both charmingly situated in the New Forest district. The first halt was made at Elmers Court on the way to Pylewell Park, the latter being about a mile distant. Mr. George Smeeth, the courteous head-gardener, met the members and conducted them round the extensive gardens, which, when completed, will extend to about twenty-three acres. There are some very attractive formal gardens here which remind the visitor of some of the old-world gardens. In quite suitable positions there are rock, water and alpine gardens of great beauty, where tiny tufts and huge masses of plants seem quite at home, judging from their flourishing condition. Very little formal bedding-out is done, but there is a wealth of flower. Large lawn areas are enclosed in clipped Cupressus macrocarpa hedges, the openings in these hedges being arched with the golden C. m. lutea, and very effective they are. Wall fruits and vegetables looked promising. Much new wall space was furnished with glass about two feet deep, and the trees were thriving under it. All the contents of the glass houses were equally well cared for. On arriving at Pylewell Park the members were received with every mark of kindness by Mr. Frank Hamilton, the able head-gardener. They were first shown the formal bedding-out in front of the mansion and the sunk Rose garden, which is laid out in formal-shaped beds with stone paths between. Some large bushes of Lavender are growing in each bed, and the whole are surrounded with Heliotrope, and outside the latter climbing Roses luxuriate on rustic trellises. Mr. Whitaker generously provided lunch and tea in a tent on the private cricket ground, a kindly thought on his part, which was much appreciated by the visitors. During the afternoon the members inspected a magnificent collection of flowering and rare shrubs. A long, winding grass slope led to the ornamental lakes, which extend to about half a mile in length. The grass slopes referred to are studded with Palms, Dracenas, Musas and other kinds of subtropical plants, and on the fringe of the woods Tree Ferns seem quite at home. They remain out all the winter. The fronds are loosely tied up and slightly protected, and bell-glasses are placed on the top. Water Lilies form huge masses of leaves and flowers on the surface of the water in the upper portion of the lake. Arum Lilies look charming peeping out of the water. Giant Gunneras spread their fan-like leaves over the waters, and Gladioli, Agapanthus umbellatus and a great variety of plants adorn the borders at the edge of the lake. Grasses are numerous. Kniphofia conspicua and Wistarias clothing the beautiful bridge spanning the water to an island must have a charming effect when in full bloom. Some clumps of Phormium tenax have spikes and leaves nearly fifteen feet high and almost as much through. A hedge of Bamboos here is very striking on account of the density and height of the individual plants forming it. Perpetual-flowering and Malmalson Carnations filled three large houses. Madresfield Court, Muscat of Alexandria, Alicante and Frontignan Grapes bore heavy crops of fine bunches in a long range of vineries, and Melons, hardy fruits and vegetables bore full crops. A striking feature in the plant-houses was Solanum Wendlandii trained under the roof glass and forming masses of blossom there. After engaging in games of cricket and quoits, the members left for home, having spent a most enjoyable time.

THE GARDEN.

No. 2231.—Vol. LXXVIII.

AUGUST 22, 1914.

NOTES OF THE WEEK.

More Flower Shows Abandoned.—We regret to say that quite a number of flower shows have been abandoned on account of the war. The Royal Caledonian Horticultural Society has decided to cancel all arrangements for the autumn show at Edinburgh. Shows at Glasgow and Brighton are abandoned, and the Royal Horticultural Society is postponing till happier times the Saxifrage Conference arranged for next year.

Our Food Supply.—From the returns just issued by the Board of Agriculture and Fisheries we are gratified to learn that the Wheat crop this year is not only 10 per cent. larger than in 1913, but is well above the average of the last ten years. The crop of Beans is the largest since 1907, while that of Potatoes is only slightly below that of last year, which was the largest on record.

The Wheat Supply.—The Board of Agriculture and Fisheries stated a few days ago that there was in this country sufficient Wheat to supply the whole population for about four months. They have now obtained more complete information, including returns of the stocks of Wheat and flour held by about one hundred and sixty of the principal millers in Great Britain. On the basis of the figures now available it may be said with confidence that there is actually in the United Kingdom at the present time, including the home crop now being harvested, five months' supply of breadstuffs. This is additional to the Wheat and flour on passage and due to arrive shortly.

Farm Horses and the Harvest.—A number of complaints have been received by The Board of Agriculture and Fisheries from farmers representing that all their working stock of horses has been requisitioned for military purposes, and that they are unable to harvest their crops, or are seriously impeded in doing so. His Majesty's Government have clearly stated in Parliament that it is their desire that such interference with harvest operations should be avoided; but where it has unfortunately happened that necessary working stock has been withdrawn, the Board of Agriculture and Fisheries would urge that neighbouring farmers, landowners and land agents should interest themselves in remedying the misfortune by some measure of co-operation, and that those in a position to do so should arrange to assist or to procure assistance for those whose stock has been removed to supply the needs of the nation.

Sugar Corn: A Useful Vegetable.—It is not easy to understand why Sugar Corn or Maize is so seldom used as a vegetable in this country. In the United States it is widely grown and much esteemed. By sowing early in the year, the

young green cobs may be had from July till October, and surely no crop could be more easily grown. The cobs must not be allowed to harden, but should be cooked while tender and served with melted butter. Among the best varieties

SUGAR CORN EARLY DWARF. A VARIETY OF RAPID GROWTH WELL ADAPTED FOR GROWING IN THIS COUNTRY

are Early Dwarf, Six Weeks, Sweet Triumphant, Country Gentleman and Concord.

Tomatoes in the Open.—Those grown out of doors must be regularly attended to, tying to their supports and removing all the foliage that is likely to hinder the early ripening of the fruits. Those grown against walls do not get the same amount of moisture as those in the open, so that they must be regularly watered, adding a sprinkling of manure from time to time.

Mushroom - Growing in Edinburgh.—The Scotland Street Tunnel, Edinburgh, which was for many years occupied as a gigantic Mushroom-house, is again to be devoted to the cultivation of this favourite comestible. It may be remembered that some years ago disease appeared among the Mushrooms, and that it was found necessary to abandon their cultivation in this tunnel for a time. It is now expected that the disease will have disappeared, and hopes of good crops are anticipated.

A Beautiful Torch Lily.—The generic name for these showy plants is *Kniphofia* or *Tritoma*, but the common sobriquet is that stated above, while they are also known as Red-hot Pokers and Flame Flowers. One of the finest, if not the best, is Lord Roberts, a grand, strong-growing variety with large, compact, bright scarlet flower-spikes, which vary in height from 5 feet to 6 feet. When shown a year or so ago before the floral committee of the Royal Horticultural Society it received an award of merit, but that body of experts considered it a variety of, or synonymous with, John Benary. However, there is no mistaking it, especially when seen at a distance by the side of the latter plant, as it is much brighter and is certainly more vigorous.

Eueryphia pinnatifolia.—Although we do not number very many Chilean species among hardy shrubs, those which are available are beautiful and worthy of extended cultivation. Some may only be grown in the warmer parts of the country, but there are others which may be planted in many parts of the Midlands or other places which possess a similar climate. *E. pinnatifolia* belongs to the latter set, and it is a very beautiful object when covered with its large white blossoms in July and August. Under the most favourable conditions, as at Trewidden in Cornwall, it grows 15 feet high and more through, a shapely bush, crowded at flowering-time with thousands of blossoms each 2 inches to 3 inches across. In some places the leaves are evergreen, but in others they fall during the winter. It is wise to plant it in a position sheltered from cold winds.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Lilium Melpomene.—Lovers of *Liliums* who like to have a nice batch of plants in the flower garden during the latter part of the summer should include the above-named variety in their collections. Good bulbs grow strongly and bear exquisite flowers of a rich colouring. In my opinion this *Lilium* is much superior to either *L. roseum* or *L. rubrum*. The flowers are borne on stems well thrown out from the main stem. It is also a grand *Lilium* for growing in pots, and looks charming in groups in greenhouses. —AVON.

A Seedling Rambler Rose.—I am sending a photograph of a peach and white coloured seedling

rubbish flowered earlier both times than another in ordinary soil of loam, peat and sand in a moister part of the rock garden. From the name of *saxatilis* one would consider this species should be a rock-lover, but it is evidently not too exacting in its needs. The deep rose flowers are very attractive. —MORAINÉ.

Two Beautiful Antirrhinums.—We have now a choice of many beautiful shades of colour among *Antirrhinums*; but when visiting the nurseries of Messrs. Dobbie and Co. at Edinburgh the other day, two of the varieties there specially attracted me. These were *Moonlight* and *Coccinea*. The former is a tall variety, and, as the firm rightly describe it, is "a beautiful shade of apricot yellow, slightly flushed with red on the upper lip." It is somewhat like Sutton's *Pale Apricot*, but the yellow is less aggressive. It received the Royal Horticultural Society's award of merit last

well in an exposed position where some other subjects less afflicted with tenderness than the ordinary *C. maritima* perished during the winter. It is thriving and has made a good plant. It is a subject which many admire for its foliage and its general aspect. I am not aware of any special name for this hardy variety. —S. ARNOTT, *Dumfries, N.B.*

Choisya ternata in Scotland.—Everybody admires the Mexican Orange, *Choisya ternata*, which forms such a handsome bush in favoured quarters, and whose glossy leaves and abundance of white flowers give great pleasure to lovers of sylvan beauty. It is never free from the suspicion of tenderness, and this doubt is too well founded, as many find, even in places where it is considered to be safe from injury by frost. It is very questionable if old plants will stand a severe winter so well as younger ones. Generally speaking, *Choisya ternata* is hardy, or practically so, in sheltered gardens in the South-West of Scotland, and there are places further North where it stands quite well in the open. I saw a good plant at Duns in Berwickshire the other day, and, though not so large as some of the bushes in the South-West, it was a really good and attractive one. We cannot hope to compete with the South of England or Ireland in our specimens of *C. ternata*, but it is a pleasure to think that in many Scottish gardens this fine shrub may be introduced with much satisfaction. A sheltered place should undoubtedly be selected. —N. B.

A Plant with Two Names.—I observe that *Houttuynia californica* is being offered as *Anemonopsis californica*, evidently a clerical error for *Anemopsis californica*, which, again, is a synonym of *Houttuynia californica*. Either *Anemopsis* or *Anemonopsis* is a misleading name, the former sounding so like the latter that it leads to confusion. *Houttuynia* is now the accepted title, and should be followed. This flower is being offered as an alpine plant, but it is very doubtful if it will prove hardy with us, and I should be glad to hear if any reader has found it capable of enduring our

winters. According to generally reliable authorities, it is a "greenhouse perennial herb," and I am not aware of any place where it is hardy. It is of rather creeping habit, and in the open is said to send out runners, by which the plant may be propagated. The ovate leaves are covered with small hairs, and it sends up stems varying from 6 inches to 2 feet in height, bearing a spike, spadix-like in appearance, with white bracts round the base. It flowers in the summer, and an American writer speaks of it thus: "The still vividly green lowland meadows suddenly bring forth myriads of white stars, which, in their green setting, become grateful resting-points for the eye. It loves a rather moist soil, and should be planted in spring. In the meantime it should only be tested in the warmer parts of the United Kingdom." —EXPERIMENTALIST.

A WELL-FLOWERED SEEDLING OF THE DAWSON RAMBLER ROSE. THE BLOOMS ARE PALE SALMON IN COLOUR, FADING TO CREAM.

of the Dawson Rambler Rose. Like the parent, it is early blooming, and very hardy and immune from disease. Its colour, though delicate, is quite distinct, and unlike any other rambler with which I am acquainted. Perhaps pale salmon, fading to cream colour, would be a more exact description than peach and white. The plant is a very heavy bloomer, the bloom this year being somewhat lighter than usual owing to a very unfavourable season. —E. K. BUTLER, *Jamaica Plain, Mass.*

Primula saxatilis Flowering Late.—*Primula saxatilis*, which bloomed earlier in the year, came into flower for the second time in July and lasted into August. It is closely related to *P. cortusoides*, and differs mainly in the longer pedicels. It is rather interesting to see how well it seems suited to the dry moraine, and a plant in one composed largely of whinstone and broken lime

September. The second variety, *Coccinea*, is an intense orange scarlet intermediate variety, a more intense scarlet even than that beautiful variety *Orange King*, with which I hope to associate it next season. —CHARLES COMFORT, *Midlothian*.

A Hardy Cineraria maritima.—*Cineraria maritima* is such an effective and pretty plant with its silvery foliage that it is a disappointment to many to find that it is not perfectly hardy with them, although it is so in mild places. I have a vivid recollection of seeing it apparently naturalised in some places in Ireland, while it is well known that in the South-West of England it is quite hardy. I have tried to grow it as a hardy perennial, and have lost it, when I had a garden in a milder district than my present one. Last year a good friend sent me a plant of a reputedly "hardy form" of *C. maritima*, and this has stood quite

A Blue Poppy for the Woodland.—*Meconopsis Wallichii* is a handsome plant growing about five feet high and producing erect pyramids of pale blue flowers. At Clandon Park it is grown with marked success and on a large scale in a beautiful woodland glade known as the Primula Dell. At Wisley, too, it is successfully grown in the woodland, where it withstands the winter without the least injury.—SPARTAN.

Iris susiana.—Those who have grown and flowered this Cushion Iris in pots this year would now do well to transfer the pots, plants and all, to the shelf of a sunny greenhouse and forget all about them for a space of three months or so. In that way the plant would receive the modicum of rest it requires, and in the so-called "baking" process become so fully matured that in all probability a better result at flowering-time another year will almost sure to follow. Only in some such way as this are the needs of this grotesque species likely to be met. Moreover, it is a gain to the gardener if he can put to sleep some of his treasures while he is enjoying the others.—E. J.

Mazus reptans in Scotland.—This charming little Mazus, still generally offered as *M. rugosus*, is doing splendidly in the moraine in the delightful rock and water garden of Mr. E. A. Hornel at Broughton House, Kirkcudbright.

A SIMPLE METHOD OF STORING FRUIT.

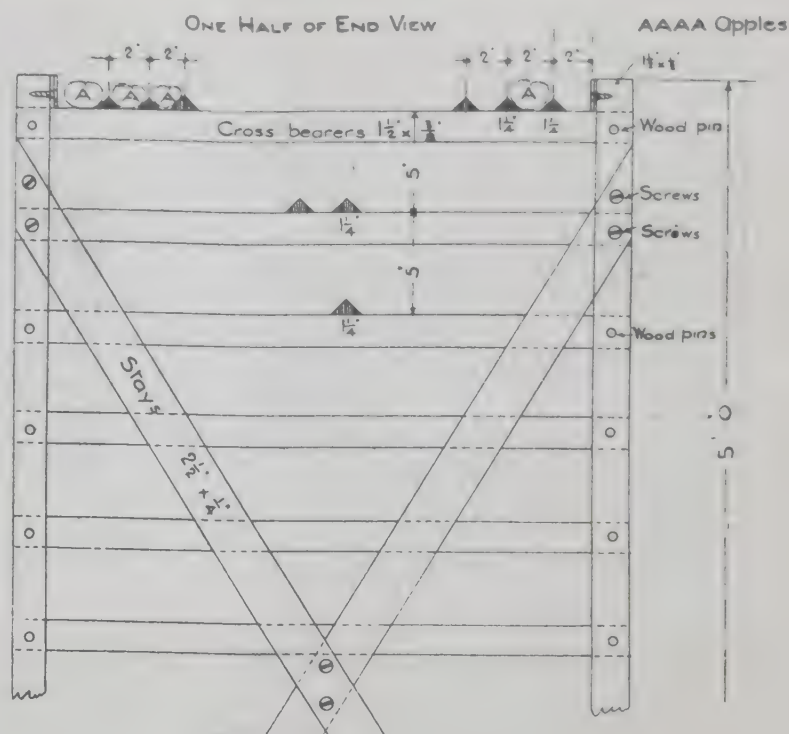

IN view of the wide interest now taken in the preservation of our food supply, we take the opportunity of reprinting from *THE GARDEN* the notes and illustrations on a very simple, but none the less useful method of storing fruit.

"I have kept my fruit in a most satisfactory manner on lattice trellis stores, and have taken the trouble to make and enclose a plan of one which I trust you will understand and that it may be of use, which will afford me pleasure after the courteous and helpful replies you have always accorded to my enquiries. My stands are made from rough sawn deal (odd pieces, in fact), and are, as you will see, 5 feet by 5 feet by 2 feet 6 inches. I have kept Apple Reinette du Canada on them until the middle of June, and attribute this success to the free air space all round

by too dry an atmosphere or by gathering the fruits too early.

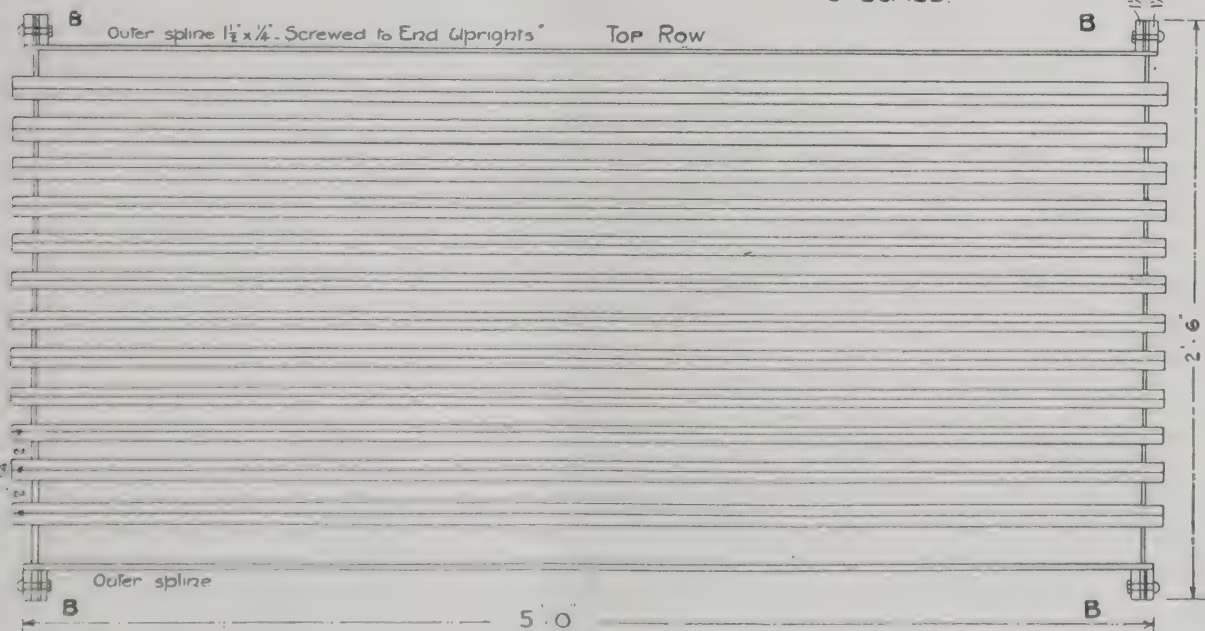

Chelmsford.

T. H. P. DENNIS."

END VIEW OF STORE. EVERY FRUIT IS VISIBLE.

3" SCALE.

PLAN OF THE TRELLIS FRUIT STORE.

It is apparently quite at home there already, and is highly pleasing among the stones, showing its dark green leaves and dainty little purple flowers so well among the gravel and shells from the neighbouring sea-coast. It was still well in bloom towards the end of July. The plants are facing full south, and the moraine slopes rapidly in that direction.

A Handsome Plant of Berberis dulcis.—One of the finest plants of *Berberis dulcis* to be seen anywhere in the United Kingdom is that in the old garden at Monreith. This I saw again the other day, and it is increasing annually in size. Sir Herbert Maxwell measured it in my presence, and it was about one hundred and five feet in circumference and quite twenty feet high. Of course, a plant such as this requires plenty of room to show its character and size, but this one has no lack of space, standing apart from other shrubs and covering this area without any crowding by other plants. It would be interesting to know if anyone has a bigger plant of *B. dulcis* in this country.—S. ARNOTT.

the fruits, which must not, of course, touch each other. I keep mine in a dry attic, and, as you will note, every fruit thereon is visible there. You will note on the plan a rough perspective view of the stand, and it is important that the strips shown at the four corners should be added front and back to attain perfect rigidity. The whole is a knockdown arrangement. I fasten the triangular strips to cross bearers, preferably with string, tightly lacing it; but there are other means by which this can be done should the space between the triangular spines be too much or too little. The chief points to remember in making a fruit store is that a free circulation of air is essential and the fruits should be visible from all sides. The shrivelling of the fruits is usually caused either

HERBS IN THE GARDEN.

THE time for the sowing of herbs is long past; nevertheless, the season of herbs is now coming, and some hints on their culture and their usefulness as decorative plants in the garden may be timely enough. It is at the present time that lovers of gardens take special interest in the plants grown, and make notes as to future treatment of them so as to secure improved effects. Herbs, I may say at once, are, in the majority of instances, much neglected. There is such a vast difference between those plants well cultivated and others which only manage to exist. Usually, the herb border is the one in which strong-growing weeds become well established.

Thyme, Sage and Mint should receive special attention, of course, for culinary purposes, but I would not hesitate to grow Sage, Thyme, Mint and Balm in flower-beds; beds suitably placed, say, near old walls or fences and

PERSPECTIVE VIEW. NOTE THE FREE AIR

buildings, or in borders near the entrance to the flower, fruit or vegetable garden. Sage and Thyme are my two favourites for growing in the way suggested. I used to make a point of raising a fresh stock of both every year; the Sage from seeds, and the Thyme from seeds and layers. When in flower the Sage bed looked grand and showed to advantage from a distance; the Thyme was not so conspicuous, but presented an equally pleasing effect from a closer view. The blue flowers of the Borage are also very telling when the plants are grown in groups. This is a good subject for cultivation in very poor soil, and will brighten up any odd corner where many kinds of plants will not live.

On the South Coast, Borage plants grow in masses in the shingle just beyond the tidal mark, the sea spray doing no harm to the plants or the flowers.

How to Propagate Thyme.—If any readers possess a few old clumps of these plants, they should deal with them in the following manner. Carefully spread out the shoots from the centre, leaving an open space there; clear away all decayed portions. Procure a sandy compost and place it in the centre of the prepared plant, filling up the space and covering quite half of the stems of the plant—the basal parts—so that only a few inches of the young points are left visible. It is, then, only necessary to keep the new compost regularly watered, and the old plants will soon root into it. Early the following spring the clumps may be divided, when hundreds of rooted layers will be available for making up fresh beds. The work of layering should be done now.

This is a good way of treating old plants that are grown solely for kitchen use, as, when so dealt with, they live longer. It will not be necessary to lift and divide the layered clumps; simply leave them as they are. I need only add, further, that herbs for drying must be cut when in full flower; then their strength as such is retained. AVON.

THE STORING OF VEGETABLES.

IT behoves all persons now to economise in every shape and form with foodstuffs and to store all possible material for future use. With vegetables a splendid opportunity presents itself, because much may be dealt with; and, as they are plentiful in gardens this season, now is the time to set about the various details necessary. I

PARSNIP TENDER AND TRUE. PARSNIPS KEEP BEST IN GROUND WHERE THEY ARE GROWING THROUGHOUT THE WINTER.

purpose detailing the best means to adopt on both a large and a small scale, whereby the cottager may prepare a supply for the future as well as his more affluent neighbour.

Potatoes.—Of all vegetables this is the most important. At the present moment the prospect of a heavy crop is encouraging, generally, although in some localities, owing to a long spell of dry weather at the end of May and during June, the prospect among the early and midseason varieties is not so good. The almost continual rain during the last fortnight, too, warns one to take all available precautions to preserve the later crops from disease as far as possible, because this is just the kind of weather to produce this pest. Any batches not sprayed should be gone over as quickly as possible with Strawsonite Bordeaux mixture dissolved in clear cold water at the rate of 20lb. to 100 gallons of water per acre. For a small patch in a cottage garden, an ordinary hand syringe will apply the mixture quite easily through a fine nozzle. Such an operation affords a splendid opportunity for co-operation in the purchase of the Strawsonite. The under side of the leaves is equally as important as the upper side, and so are the stems. Early and midseason varieties should be lifted, dried and carefully stored in sheds or in heaps, and protected from rain by a slight covering of straw, Bracken, dried grass and then a coating of soil. When putting the Potatoes in heaps, a small quantity of air-slaked lime is a good preservative of the tubers, and no doubt wards off disease to some extent. Smaller quantities can be stored in boxes. Those who do not spray the later batches directly

they see the first sign of disease in the leaves would do well to cut off the haulm quite close to the soil, as undoubtedly the disease penetrates the tuber through the stems.

Carrots, Beet and Turnips should be left in the garden until fully grown, but not afterwards. They are easily stored for months in sand in a shed or cellar, or in the open, protected from too much wet and frost. If sand is not available, they can be massed in a heap and covered over with any light material underneath a thick coating of soil.

Couve Tronchuda and Celeriac may be treated in a similar manner, but not in such quantities as the foregoing kinds.

Parsnips keep best where growing until quite late in the spring; in fact, until new growth in the leaves is on the move, when they should be lifted and stored in sand in a damp situation. Should early frost take place in the autumn, cover the crowns with soil 4 inches thick to preserve that portion of the root exposed by the growth of the leaves.

Leeks keep best where growing, except, perhaps, those matured quite early for exhibition. These, when growth is complete, should be lifted and stored in a dry place with moist soil about them, still retaining their roots.

Celery will come under the same category as Leeks, keeping better where growing as long as the hearts are protected from excessive rain; this, when followed by frost, is the principal cause of decay.

Vegetable Marrows can be preserved over a long period, and as they are plentiful this season they afford a good opportunity of prolonging a supply. When the Marrows are fully grown and before they become hard in the skin, they should be cut and hung up in a cool, airy shed. The time to cut is best ascertained by inserting the thumbnail in the skin of the Marrow near the stalk, if it penetrates easily, they should not be cut. The larger fruits, as Long White, Green and Cream, should be allowed to grow to their full size and mature fully. These will keep in a dry room for months, and can be made into jam or used for pies at will.

Cabbages, when nearing maturity, should be half pulled up, severing a portion of their roots in the ground. This will check growth and prevent them running to seed.

Cauliflowers, as they approach maturity, should be pulled up, standing the roots in water in a cool shed or behind a south wall, where they will keep fresh for some time.

CARROT NEW RED INTERMEDIATE. CARROTS MAY BE STORED FOR MONTHS IN SAND IN A SHED OR CELLAR. SEED SHOULD BE SOWN NOW.

Salsify and Scorzonera should be treated in the same way as Carrots and Beet.

Runner Beans may be induced to bear longer by removing the Beans as fast as they grow to their full size and before they form seed, and thus relieve the plant of an undue strain. If the plants can be protected also from early frost, so much the better. The Beans are best preserved by standing the stalks in water, and although they may not last long, a few weeks saved may be useful.

Jerusalem Artichokes should be left in the soil until required, as they keep better there than anywhere until new growth commences in April.

Globe Artichokes ought to be cut directly they attain full size and before they harden. Stand the stems in water in a cool shed or under a wall away from the sun's rays.

Onions must be carefully handled. Directly the tops exhibit signs of maturity, they should be pulled up, laid thinly in the sun to thoroughly ripen, and then be suspended in ropes or singly from the under side of the roof in a cool shed, or be spread thinly on a boarded floor. The early growing Tripoli varieties may be longer preserved than ordinarily by pulling them up directly their full growth is assured, removing the slightest sign of decayed skin and giving them an airy position.

Cucumbers keep best placed in a box one layer thick on green Nettles and buried 1 foot below the surface.

Rhubarb is best made into jam when fully matured in its growth.

With regard to the growth of such crops as Brussels Sprouts, Savoys, Broccoli, Kales and other winter vegetables already in existence, these should be encouraged to grow to their fullest extent by keeping them free from weeds and constantly stirring the soil.

BROCCOLI CHRISTMAS WHITE. BROCCOLI, CABBAGE, SAVOYS AND KALE ARE VALUABLE WINTER CROPS, AND MAY BE PLANTED NOW.

Sowing and Planting.—Every available piece of ground between fruit trees should be planted with Cabbage, Coleworts, late Savoys and Kales. Quantities of Spinach, Onions, Carrots, Turnips and so forth should be sown without delay among Strawberries or on any vacant places; even flower-beds might be extemporised for such crops as are still available by planting and seed sowing. Appearances in the garden are of little avail in case of such dire necessity as we may be put to in the near future, when sentiment avails but little.

The preserving of such vegetables as Peas, Kidney Beans and green Tomatoes in bottles, too, should not be forgotten. E. MOLYNEUX.

Swanmore Park, Bishop's Waltham, Hants.

HOW TO PRESERVE FRUIT WITHOUT SUGAR OR ANY SPECIAL APPARATUS.

Materials Needed in Readiness.—Boiling water sufficient to fill the fruit bottles. Clarified mutton fat, melted and ready to use. (Put this in a jar, into the oven, while the fruit is cooking.) Vegetable parchment covers to fit over all the bottles, and fine strong twine cut into lengths to tie down each jar quickly.

Method.—Gather the fruit on a dry day, and, having provided clean teacloths, very carefully wipe the fruit, laying aside any that are over-ripe, split or in any way imperfect. Place the clean, dry fruit gently in perfectly clean, dry, wide-mouthed bottles or jars, such as old French Plum bottles, good sound glass jam jars, &c. (but do *not* use any that have contained pickles or vinegar). After filling the bottles with the fruit, gently turn and keep patting the bottles. In this way the fruit settles down, so that you will find you can add some more fruit to each jar after it is apparently quite full. Next stand the bottles in an open vessel, such as a large fish-kettle or any large saucepans, &c., and put clean straw, hay or rags between the bottles to prevent them from shifting while cooking. Fill the large vessel with cold water till it reaches to about two inches or three inches below the tops of the jars. Let it gradually boil up, and keep it boiling till the fruit at the bottom of the jars just begins to show signs of cracking. Then ("I can't be interrupted to speak to anyone, not even the Queen if she should chance to call") fill the bottles with boiling water from the kettle, thoroughly covering the fruit (as it often soaks up a little of the water), and carefully and quickly add just enough of the melted fat to entirely cover the surface of the water.

ONIONS SHOULD BE WELL RIPENED BEFORE STORING, TAKING CARE NOT TO BRUISE THE BULBS. THE VARIETY RECORD IS HERE ILLUSTRATED. SEED SHOULD BE SOWN NOW.

Tie the vegetable parchment covers over the jars instantly. Set the jars to cool, and wipe every one before storing, in case any of the fat should be on the outside. Store on cool, airy shelves. Fruit preserved thus will keep good for twelve months.—ANNE AMATEUR.

BOTTLING LATE FRUITS.

MUCH has been written from time to time on this important subject by far more able pens than mine, and I do not for one moment pretend to teach experts the best way; but with every appearance

of serious times in front of us it behoves each man to do his best both to prevent waste and make every preparation for the future. For many years my good wife has taken much interest in this direction, and I venture to say that in some cases many fruits which she has preserved in this way are equal, and even in some cases superior, to fresh fruits. Especially does this relate to Plums, Damsons and Morello Cherries. Fortunately, it is by no means necessary to have the best varieties for this purpose; indeed, some of the smaller and more common sorts of Plums are to be preferred to the choicer varieties for this purpose. Damsons, for instance, are among the most simple to preserve, and when properly done the true Damson flavour is much more pronounced after six months than when freshly taken from the tree. Where heavy crops of Plums abound, fruits which are even not yet ripe may be thinned and bottled with much success.

Pears.—With the heavy crop of this fruit in many parts of the country, and with the short time many varieties will last when ripe, means should be taken to preserve them. Nearly all varieties will lend themselves to it. The small ones may be peeled and bottled whole, and the larger ones cut into quarters. These make a very wholesome and appetising dish when stewed.

Morello Cherries.—Though these are not nearly so largely grown as many other fruits, few things are more appreciated or more delicious after being bottled, and can be served up in many ways.

Another important fruit which should not be overlooked, and which is within the reach of most of the poorer among us, especially those in the country, is

The Common Blackberry, which finds favour when nicely cooked with both rich and poor alike.

Rhubarb, though not strictly a fruit, is generally included as such in fruit-bottling classes, as it naturally ranks as a fruit dish on the table. By choosing the younger leaf-stalks and cutting

them into suitable lengths, these preserve well and will answer splendidly for making fruits and tarts during the winter months.

Bottling the Fruits.—There are many forms of special bottles manufactured expressly for this purpose, the majority of which are particularly well adapted. Always select those which will have nothing but clear glass next to the fruit after being screwed down. Medium-sized bottles are to be preferred to the larger ones, as the contents will not keep for any length of time when once opened. Select sound fruits which are rather under than over ripe, and these should be graded. Pack evenly and firmly into the bottles till within a short distance of the top; the fruits should be covered with cold, clean water, leaving a small

of the vessel when the bottles are being heated to prevent them coming into direct contact with the heat. EDWIN BECKETT, V.M.H.

JAPANESE MAPLE AND CAMPANULA PELVIFORMIS.

JAPANESE MAPLES are very slow in growth, but they spread out into dense heads and have a fine appearance when well placed. They may be recommended especially for small gardens, as the several varieties occupy but little space and contribute a rich scheme of colours, from deep crimson to light green. To give an idea of the slowness of growth, I may mention that the plant shown in the accompanying illustration has been in its present position for thirty years, but is still under six feet in height. It is a specimen of *Acer polymorphum dissectum*, with leaves most elegantly cut to such an extent as to give it the appearance of some delicate Fern rather than a Maple. The colour of the foliage is deep reddish bronze, which is especially bright and conspicuous during the early summer. The slender branches are of an elegant drooping, almost weeping, habit, and it is a gem for the foreground.

The colours of the Maples are very effective, varying from light green and golden yellow to all shades of red, bronze and dark purple, while in the autumn many kinds assume a bright scarlet, which is retained during several weeks before the dropping of the leaves. Another strong point in favour of these Maples is their extreme hardiness. Even in the North they flourish without protection during the winter. All they need in exposed localities is a little shelter in the early spring from cold or boisterous winds, which might damage the young foliage before it is fully developed. Owing to the dwarf character of their growth it is very necessary when planting to place them in a prominent position, as, unless they come directly under the eye, the beautifully formed leaves and the exquisite markings are not seen to advantage. Arranged in bold groups, the brilliancy of colouring for which these Maples are so remarkable in the autumn is a striking and uncommon feature.

Campanula pelviformis is said to be a variety of *C. carpatica*, but it is sufficiently distinct to be treated as a species. It is one of the most attractive forms known. Instead of the well-known flowers of *C. carpatica*, the large blossoms of *C. pelviformis* are deeply saucer-shaped in form, and carried on freely branching stems that are about a foot high. It should be found in every collection of hardy plants, for it is certainly one of the best of its class, and both compact and free-flowering. The blossoms, which are about two inches across, are pale lilac. The seedlings rarely approach in any degree to the parent plant, but revert to the *C. carpatica* type. WYNDHAM FITZHERBERT.

A BEAUTIFUL JAPANESE MAPLE IN ASSOCIATION WITH CAMPANULA PELVIFORMIS.

air space of about half an inch. The rubber ring ought then to be placed on, and next the glass top. Finally screw down the collar tightly. The bottles should be stood in rather a large pot or boiler specially made for the purpose, which ought to be stood on a fire or a gas stove, allowing the temperature to rise slowly to about 160° Fahr. This will take about an hour and a-half. It can easily be tested by the thermometer, after which allow them to cool down gradually, when the bottles may be placed in a dry, cool store cupboard, where the fruits will keep for months and, indeed, in many cases for years. It is well to place a large plate or small dish at the bottom

HARDY HIMALAYAN PRIMULAS.

(Concluded from page 412.)

P. sikkimensis (Hook.).—Another well-known plant is *P. sikkimensis*, which is quite hardy, but which many find short-lived in gardens. It is a lover of moisture, and in its native habitats chooses marshy situations. It seeds freely and comes readily from seed, so that it is easily retained, even in places where the old plants die off. It needs no description, and its tall stems, bearing their abundant fragrant, light yellow flowers, please everyone. As the name would indicate, it comes from Sikkim, where it is found at an altitude of from 11,000 feet to 15,000 feet. *P. sikkimensis* belongs to Watt's section *Purpurea* and Pax's *Nivalis*.

P. Stuartii (Wall.).—The true *P. Stuartii* from Thibet, Kashmir, Chamba and Sikkim has yellow, perfumed flowers; but much confusion has arisen between it and *P. purpurea*. *P. Stuartii* has the leaves minutely serrate, those of *P. purpurea* being almost entire. It is usually found in wetter places than *P. purpurea*, and in cultivation prefers a good supply of water. It is a handsome plant, with lemon yellow flowers on long, spreading petioles. It belongs to Pax's *Nivalis* and Watt's *Purpurea*.

P. Wattii (King).—A beautiful little plant, which with me has not proved hardy. It belongs to the same section as *P. Reidii*, and requires much the same treatment. The drooping flowers are of a fine dark purple colour. It was introduced into this country some little time ago, and when first shown in London by Messrs. Gill it caused quite a sensation, people failing to recognise it.

P. Winteri (Gill).—This is synonymous with *P. petiolaris* var. *pulverulenta* of Hook. f., but Mr. W. G. Craib is of the opinion that it is a good valid species, and that it should not be considered as a variety of *P. petiolaris*. With this conclusion most of those who know the plant will agree. It is a handsome species, with very farinose leaves and pretty rose lilac flowers. It has not been much tested outside, and has generally been cultivated in pots in a cold house, for which it is well adapted. It is well worth growing for the sake of its beautiful mealy foliage, apart from its flowers.

Morelands, Duns.

JOHN MACWATT.

A BEAUTIFUL JAPANESE GUELDER ROSE.

VIBURNUM PLICATUM is the sterile form of the Japanese Guelder Rose, *Viburnum tomentosum*, and one of the best, if not the best deciduous flowering shrub in the genus. The illustration is sufficient evidence of its free-flowering qualities. It forms a spreading bush 5 feet to 8 feet high, with prominently ribbed green leaves, which are almost hidden in June by the pure white flowers. These are borne in globose inflorescences, 2 inches to

3 inches across, not unlike our common Snowball Tree; hence the popular name of the Japanese Snowball Tree is frequently used. As a lawn specimen or a group of six to a dozen plants in a large bed and massed in a border, nothing could exceed this *Viburnum* in beauty when in blossom, rising like a mound of snow from a green carpet. *V. plicatum* was first introduced by Fortune in 1844. A second variety, *Mariesii*, is also a good garden plant for sheltered positions, its behaviour suggesting that it is not quite so hardy as the subject of this note. Cuttings made of the half-ripe wood root readily in late summer in a propagating-frame with slight bottom-heat, or on a gentle hot-bed. Layering is also an easy method of increase. *V. plicatum* luxuriates in a rich loamy soil. Mulching with decayed manure in June, liberal supplies of water during dry weather, with occasional applications of liquid

Kew in a bed of the Mediterranean Heath. At home, in South America, *E. pinnatifolia* is an evergreen, but during a severe winter with us many of the leaves turn brown and fall before the new ones push in spring. It belongs to the Rosaceæ family, and the large white flowers, 3 inches across, with a central mass or rosette of stamens, may be compared to a choice single Rose. The most suitable soil appears to be sandy loam in which leaf-mould and peat have been freely worked. *E. pinnatifolia* is without doubt one of our choicest August-flowering hardy shrubs.

ASCLEPIAS DOUGLASII.

This hardy perennial, though introduced into this country in 1846, is little known in gardens, in proof of which it may be mentioned that in the last sixty volumes of *THE GARDEN* only one

JAPANESE GUELDER ROSE OR SNOWBALL TREE (*VIBURNUM PLICATUM*.)

manure, all assist in producing a picture such as the one shown.

A RARE CHILIAN SHRUB.

ALTHOUGH introduced about fifty years ago, *Eucryphia pinnatifolia* is still a comparatively rare plant. It seems to thrive best in a half-sheltered spot where the shrubs get plenty of light but are sheltered on hot, sunny days. Another requisite appears to be moisture and cool conditions at the roots, for though the ground must be well drained, it is rather noteworthy that usually the best specimens are those surrounded with low-growing shrubs some 2 feet to 3 feet in height. The conditions named can perhaps be most readily supplied in the South and West, where good specimens may be noted. At Wisley two noble specimens are flowering profusely at the present time, while others are to be seen at

note on it, a few lines in length, occurs. It is, however, a handsome plant, worthy of culture for its foliage alone, while its sweet-scented blossoms render it desirable. In Nicholson's "Dictionary of Gardening" its height is given as from 2 feet to 3 feet. The entire leaves are 1 foot in length and 4½ inches in breadth, and the plant, when it has attained its fullest dimensions, has a very noble appearance. It flowers in August, bearing numerous heads of small blossoms, some of the bloom-clusters having a circumference of 12 inches. The globes of flower, when all the blossoms are fully expanded, appear of a faint flesh pink colour at a little distance. The reflexed petals are of a dull reddish hue, and the corollas, which are less than half an inch across, are of a yellowish tint. Over two hundred blooms are often carried on a single flower-head. As has been said, the blossoms are perfumed, and innumerable humble-bees are attracted by the scent to the bloom

heads, where they soon lie prone, intoxicated with the nectar. The plant is a native of Western America and is a very strong grower, spreading by underground stems. If a specimen is shifted, any little portion of the roots that may be left throws up growth in the spring. A better-known species and the showiest flowerer of the race is *A. tuberosa*, which bears flat umbels of brilliant orange scarlet flowers on stems about 2 feet high. It will not succeed in heavy soil, but in light ground and in full sunshine it should do well.

Kingswear

W. F.

A BEAUTIFUL ROCK ROSE.

CISTUS LORETII is one of our best Rock Roses, and is a hybrid between *C. ladaniferus* and *C. monspeliensis*. It forms an attractive evergreen bush 3 feet or more in height, and, being of a spreading habit, usually exceeds its height in

CISTUS LORETII, A HARDY AND FREE FLOWERING ROCK ROSE.

diameter. The leaves are small—1 inch to 2 inches long—and the flowers are in terminal clusters of three to five blooms, white, with a crimson blotch at the base of each petal. The flowers are 2 inches or rather more in diameter and, in common with other Rock Roses, open in the morning and shatter before night. There is little evidence of this failing, however, as the bushes continue to produce a profusion of blossoms in succession throughout June and July.

It is worth noting that the flowers of *C. loretii* remain open for a portion of the afternoon, whereas most Rock Roses shatter about midday. This is one of the hardiest *Cistus*es, and must be included in a selection of the best six for garden decoration. The Rock Roses delight in a well-drained sandy soil and warm sunny positions on sloping banks or at the foot of a south wall or fence. Cuttings root readily in autumn in a cold frame or under a handlight, and artificial heat is not desirable.

A. O

HOW TO INCREASE THE FOOD SUPPLY.

THE Royal Horticultural Society is doing an excellent work in bringing to notice the various ways in which our supplies of vegetables may be maintained throughout the coming months. Happily, our supply for the time being is all that can be desired, but the question which calls for immediate attention is the sowing and planting of vegetables for future use.

At Wisley every square foot of available land is being cropped, and surplus seeds have been distributed among cottagers in the neighbourhood. This worthy example has been followed in many towns and villages throughout the United Kingdom. We know of many places, particularly in the

vegetable in the form of Turnip tops. For some unknown reason garden Swedes are not very extensively grown, but wise country folk well know that the Swede is a better vegetable for cooking in the winter than even the Turnip. Moreover, Swede tops may be used for cooking in the same way as Turnip tops, while the cultivation of the two vegetables is similar.

Carrots.—The varieties most recommended are Shorthorn and Intermediate. It is not to be expected that they will make a large size, but they may be allowed to remain in the soil and be drawn at any time in the winter, while in favourable soils and situations early roots may be drawn by the end of September or early in October.

Beetroot.—If sown at once, and given a favourable autumn, a yield of fair-sized bulbs may be expected in about ten weeks. Only the Egyptian or Turnip-rooted variety should be sown.

Onions.—In view of the fact that large quantities of Onions are annually imported from the Continent and Egypt, it is not unlikely that our supplies will be short, and already the market prices are high. All Onions are hardy, and it is a common practice to sow about mid-August, so that the plants are forward enough to be useful before winter. Tripoli Onions are specially recommended for sowing at the present season, and the bulbs may either be drawn in winter or allowed to stand until the spring. Onions require a rich and deeply worked soil. Light soil should be trodden over to consolidate it before the drills are drawn.

Leeks.—It is not too late to plant out Leeks, and these might be lifted at any time in winter.

Cabbage and other Winter Greens.—These provide the most important of all the winter crops. The main batch of spring Cabbage should be planted without delay and surplus plants distributed. Plant closer than usual to economise space; when cutting in the spring, every alternate plant may

be removed, giving room for others to develop. After planting, it is a good plan to cover the surface with finely sifted coal ashes as a preventive measure against slugs. Sprouting Broccoli, Savoys, Kales—especially the Russian Kale—and Coleworts should all be planted now to yield valuable crops all through the winter and spring. Any open piece of ground will suffice, even between permanent crops of small fruits, provided it is deeply dug and not exhausted by previous crops.

Winter Spinach.—On light soils and in country districts, away from the evil effects of town fogs, this acceptable vegetable may be sown until the end of September. When small, the plants may be drawn to make room for others to develop. It is a mistake to remove the leaves before the plants have attained a fair size. Keep the soil well stirred between the rows; give an occasional dusting with soot to clear the ground of slugs and, at the same time, assist the plants in making growth.

county of Surrey, where committees have been formed, and vacant land has been, and is still being, brought into cultivation. The committees are doing admirable work, not only in the distribution of seeds and garden tools and in the securing of suitable plots of ground, but also in giving useful work to many who would otherwise be unemployed. This work is of the greatest national importance, and there is no time to lose, as the season is not far distant when vegetative growth will cease for the year. The following is a list of vegetables which may be sown or planted now, and many of them, it may be observed, would be ready for use in less than two months.

Turnips and Swedes.—Such varieties of Turnips as will keep—for example, Red Globe and Golden Ball—are recommended for sowing at the present time. They may be sown both in heavy and light soils, and if grown in the latter should be ready by the middle of October. If allowed to stand for the winter they make a most useful

GARDENING FOR BEGINNERS.

MELONS IN HOUSES AND FRAMES.

AMATEURS who are successful in the cultivation of Cucumbers often fail to grow Melons satisfactorily. Of the two the latter are the most tender, but failure is frequently the result of undue coddling. The young plants are subjected to excessive heat, the stems and leaves are rendered quite delicate, and then, when the time comes to stop hard firing and to admit more air, the plants fail. A medium course is best. The plants mostly collapse when the fruits are beginning to net prior to the ripening stage, so that, practically, the whole of the work expended on them is useless.

Plants bearing fruits in an advanced stage now should be closely watched. Maintain the soil in an even state as regards moisture, giving manure-water immediately after clear water, and in sufficient quantity to well moisten the whole of the soil in the bed and almost close up to the stems of the plants. I do not think I have ever lost a Melon plant through watering, and when giving clear water I always poured it on the soil close up to the stems of the plants from the seedling to the ripening stages. Manure-water was kept about two inches away from the stems. Amateurs of little experience, however, would be well advised to refrain from wetting the soil nearer than 2 inches to the stem of the plant. All young shoots that are regarded as surplus ones must be pinched off—not cut—while very small; then there will be no risk of the stems damping off.

Melons, unlike Cucumbers, thrive best in a fairly heavy loam, and when planted in the latter and top-dressed with that of a similar nature the plants rarely collapse; but they often do so when grown in a very light, sandy mixture. As long as the foliage is free from insect pests it is not advisable to syringe it. Judicious ventilation at the top of the house only until the fruits begin to ripen, and plenty of floor moisture, will be all that is required. While the Melons are actually maturing on the plants, open top and front ventilators, but damp the path or floor of the house as much again while they are open. Admit a little air through the top ventilators all night, but cease damping the floors at five o'clock in the afternoon. Plants in frames require less damping and less watering than those in houses. Very great care should be taken to remove surplus shoots while small, and so avoid overcrowding. Dispose the main stems thinly over the bed surface; then ventilation, without causing direct draughts, will be more effectual. Raise the half-grown fruits on blocks of wood or empty flower-pots.

AVON.

HOW TO IMPROVE GROUND FOR VEGETABLES.

EVERY year new plots are dug up and cropped with vegetables. In some instances the newly broken soil is very good, and does not need much labour to bring it into a good condition for yielding first-rate crops; but in the majority of cases a good deal of labour is needed and much care in the working of the soil and the application of manures. There is no time better than the present for "taking stock," as it were, of the real state of ground

which was broken recently and cropped for the first time this summer. Another ordinary digging or trenching would much improve it, but the cultivator must lose no opportunity to get the soil into the best possible condition. In no case must the clayey subsoil be brought to the surface and mixed indiscriminately with the top layer for at least three years. At the end of that time, through yearly tillage, the soil to a considerable depth will be vastly improved, and some of the subsoil may then be mixed with the surface portion.

In many gardens there is a clayey soil and also a light one. In such cases the cultivator should, while carrying out trenching work, throw out spadefuls of the clayey subsoil at every few yards as the work proceeds, wheel it away to a corner of the garden, tip it down in rough heaps, and leave it there for the frosts and weather generally of winter to act upon it. One turning may be advisable about the end of January. By the end of April the stiff loam will be in a pulverised state and very suitable for mixing with lighter soil. The soil which is added must be kept near the surface, not buried, then it will still be under the influence of the weather. Rotted manure may be mixed with the clayey portion of the soil in the autumn, and with the lighter portion next February. The pulverised clayey soil would be splendid for Roses. In the heavy soil Broad Beans, Cabbages, Cauliflowers and winter greens may be grown; and in the lighter soil Dwarf Beans, Peas, Beet, Celery, Potatoes and Carrots may form the principal crops. By judicious treatment from year to year the soil would be so much improved and enriched that very heavy crops could be obtained from it at a low cost as regards the tillage.

GAILLARDIAS.

WHEREVER this very showy herbaceous plant is once grown it is always grown, for by experience its several distinctly good points quickly reveal themselves. It is, for instance, practically weather-proof, a most valuable advantage, in view of the varying meteorological conditions which obtain in our land. Under the hottest sun, when, maybe, other plants are apparently lifeless, or thereabouts, Gaillardias are in perfectly happy mood, raising their brilliant heads of colour well up on straight, stiff stems, as though oblivious to such things as variations of temperature. Heavy rains seem to affect them just as little.

Few flowers can equal them as cut blooms, and on this account they are favourites for home decoration purposes. They need, of course, to be gathered young, *i.e.*, before the ring of petals has become quite flat. As exhibition subjects, too, they are invaluable, and if given reasonable time soon recover after a journey. The plants possess, however, one eccentricity, especially those more than a season old. They sometimes throw up quite good and healthy ground growths, but without flower-spikes. In order, therefore, to obviate such a disappointment occurring, as well as to increase one's stock of plants, now is an opportune time to lift any clumps that may not have flowered, dividing out the rootlets into light soil a few inches apart. Growth emerging from flowering plants may, of course, be treated similarly. It is well to mark the spot, because frequently the leaves die quite

away; but this should not be taken as a sign that the roots are dead. In due time they will spring up. Apart from a dressing of some insecticide, soot or lime, no further attention will be necessary until removal in spring to more permanent quarters in the border, either singly or in clumps of three or four, the latter giving a bold effect.

B. W. LEWIS.

BEDDING VIOLAS OR TUFTED PANSIES.

CHARMING alike to form a carpeting for taller plants or to provide masses of colour by themselves, the above are now deservedly popular not only in the large private establishments, but also among amateurs. Undoubtedly, a great point in their favour is their adaptability to both climate and soil, though probably the ideal soil is one of a light, sandy loam to which some well-rotted leaf-soil has been added. The position for planting, if possible, should be an open one, more especially when the Viola is used in a bedding scheme, as it tends to retain its compactness of growth better than when in a shady position.

The propagation of the Tufted Pansies is simplicity itself, and can be successfully accomplished without the aid of glass at all, although, of course, where a cold frame is available, so much the better. To obtain a good supply of suitable cuttings at the present time, some of the plants should be cut back when decaying flowers are removed. This will at once encourage plenty of young growth in the centre of the plants, and if a little finely sifted soil has been previously given, all the better. Should these have to be inserted out of doors, a nice sheltered spot, where it will be an easy matter to constantly spray overhead until roots are formed, should be selected, and also where (assuming they are to remain there until spring) they are as little exposed as possible to unfavourable weather.

If possible, the cuttings inserted outside should be put in by the end of the first week in August, but where frames are available, any time up till the end of September will do. In each case a light soil should be prepared and made moderately firm, an inch of sharp sand being placed on the surface before the cuttings are inserted.

Another ready means of increase is to split up the plants during October, and they can then be replanted at once, care being taken that each portion has sufficient roots to enable it to make another start. It is essential for plants in frames to be exposed as much as possible and, after the cuttings are struck, gradually hardened, the lights being kept off except during times of severe frost and heavy rains. The young plants outside can be protected by dry leaves, Bracken or mats.

There are many excellent varieties to choose from, but the following are a few which can be relied upon: Purple—Archie Grant and William Daniels; light blue—Maggie Mott, Sir Robert Pullar and William Robb; white—Purity and Lady of the Snows; lavender—Kitty Bell and John Young; blue—Campbell Bannerman, True Blue and Admiral of the Blue; violet—Bluebell; yellow—Sydney, Lord Kitchener, George Palmer and Primrose (lemon yellow).

Scribby Gardens, Bawtry.

H. TURNER

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Peach and Nectarine Trees in pots which are intended for early forcing should be carefully examined, and all that require repotting may be attended to at once. The soil for this purpose should consist of rich turfy loam and a little decayed manure, with a good sprinkling of sifted lime rubble to keep the roots in a healthy condition. The pots should be quite clean and not too large. Pot firmly and give a good soaking of clear water as soon as potting is finished. A little crushed bone may be mixed with the soil with advantage. Stand the newly potted trees on a bed of ashes and secure them against strong wind.

Strawberry Plants in Pots will now require careful watering. Remove all side growths and keep the surface of the soil quite free from weeds. Pot up the remainder of the plants with as little delay as possible.

Early Hamburgh Vines.—All lateral growths may be removed from these Vines, and the shoots shortened in order to plump up the buds near the base of the spurs. Keep the ventilators fully open at night, and syringe the Vines in order to retain the remaining foliage as long as possible.

Plants Under Glass.

Tuberous Begonias which have been in flower for some time should receive frequent supplies of liquid manure with a view to lengthening the flowering period. Spring-raised seedlings will still benefit by potting, for, if once allowed to become stunted in small pots, many of the flowers drop before they are fully developed. Employ sufficient fire-heat to keep the air dry, and ventilate freely during warm days.

Calceolarias.—Do not allow these plants to become stunted in small pots or to become dry at the roots, as, no matter what the treatment may be afterwards, they will never present the same appearance as plants which have been grown without a check. Keep them in a cool pit and damp the pots and their surroundings frequently. Ventilate freely and protect from sun.

Carnation Souvenir de la Malmaison.—Young plants which were layered early in July will now be ready for potting into 4-inch pots. The compost may consist of good turfy loam and leaf-soil, with a good sprinkling of sifted lime rubble and silver sand. Pot firmly and place the plants in a cool house or pit.

The Flower Garden.

Propagating Bedding Plants.—This work must be accomplished with as little delay as possible, so that the young stock may be well rooted before the season is too far advanced. When sufficient *Pelargonium* cuttings have been secured, *Verbenas*, *Heliotropes*, *Coleuses*, *Iresines* and various other plants should be propagated, and for these a close, cold frame will be necessary. Let the cuttings be as stocky and short-jointed as possible, and select only such shoots as are free from flowers. When the cuttings are ready, they must be made firm in fine sandy soil, either in pots or pans.

***Anchusa italica*.**—Now is the proper time to secure a stock of this indispensable border plant, which is easily propagated by cuttings of the roots. Plants which have finished flowering may be lifted and the root cuttings prepared in the same manner as *Seakale*. They may be inserted in boxes of sandy soil with a propagating dibber and covered with soil. Place them in a close, cold pit until a fair amount of growth has been made.

Salvia patens may also be propagated now. Select short-jointed cuttings and place them singly in small pots. If kept in a close, cool pit they will soon make roots and the young tubers can be potted in spring. They will then make good plants for the mixed border in May.

Pentstemons are flowering freely this season, and the leading shoots should be removed as soon as they have finished flowering, in order to produce stocky cuttings for next season. Mrs. Fulford is a grand variety with long spikes of bright red flowers, and is worthy of extensive cultivation.

The Hardy Fruit Garden.

Apples and Pears.—Early varieties of Apples and Pears should be carefully gathered before they become too ripe, and placed in the storeroom. Later varieties which will keep for a time will be of great value this season, owing to the scarcity of foreign fruit; therefore these should be protected by netting, especially if birds are troublesome. Expose the fruits to sun by the removal of any leaves which overhang them. Any large single specimens may be secured to the trees by matting, and to secure their full development a watering with liquid manure may be frequently given. Plums should be often examined and the fruits gathered before they become too ripe, or many of them may split.

The Kitchen Garden.

Parsley.—Another sowing of Parsley may be made in a sheltered position for use during the spring, and where box frames can be placed over the crop during sharp weather. This is sometimes a useful crop during February and March, after which the frames may be removed for some other purpose. Early sown Parsley may be cut close to the ground now in order to produce a quantity of stocky growths for winter use.

Beetroot.—The earliest sown Beets should be lifted and stored in dry sand before they become overgrown, or the roots will be of no value. Later sowings may be allowed to remain in the ground for some time yet.

Tomatoes out of doors should have the foliage well trimmed, so that the crop may be fully exposed to the sun. Water freely with liquid manure, stir the soil about the roots, and top-dress with artificial manure previous to applying clear water.

Onions.—Many of the spring-sown Onions will be ready for lifting, and this should be done before the bulbs commence a second growth.

Cabbage.—Another sowing of Cabbage seed may be made now, as early sown plants sometimes suffer if they are too far advanced during the winter. Sow in an open position and prick out the plants as soon as large enough to handle. Flower of Spring, Milecross Marrow and Early Offenham are good varieties for this sowing.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions.—As a rule Onions are looking well, but owing to the recent unsettled weather they are much too green at this date, and in consequence of this second growth there is evidence of a good many thick necks. These growths should be checked as soon as possible by having the necks twisted to encourage the swelling of the bulb. Those that are showing signs of ripening ought to be pulled up and spread out to dry.

Tomatoes.—The young plants from seed sown at the beginning of the month should now be ready for potting on. It will be as well to pot them into the fruiting pots right away, just covering the ball, when a little soil can be added from time to time. Admit air night and day to promote a sturdy growth, and all laterals should be pinched out as they appear. When a sufficient number of fruits have set, feeding may commence and the temperature be increased somewhat.

Lettuce.—Another sowing of some of the hardier varieties may now be made, and as soon as they are large enough to handle should be pricked out into frames or pots which have been made up close to the glass, only protecting with the lights when there is danger of frost. This batch can, of course, be grown on outside for a time and afterwards transplanted into frames. This, however, must be determined by local conditions.

General Remarks.—With the recent showery weather there is sure to be an abundant crop of weeds appearing, and, if these are allowed to get ahead, it will be no light task to keep them in check. Every effort, therefore, should be made on fine days to get the hoe and rake at work. Continue to clear off all crops and vegetable matter that are no longer required, as these soon become offensive.

The Flower Garden.

Herbaceous Paeonies.—These, like many other herbaceous plants, resent frequent disturbance at the roots, nor is it necessary to replant them often, provided they are mulched with good manure and soil at least once a year. Where, however, the soil seems to be thoroughly exhausted, it will be wise to have them replanted, and this may be successfully done, provided extra care is exercised in lifting them. Should the weather be favourable for planting, there is perhaps no better time than the present to do this work.

Pentstemons.—Where a large stock of these brilliant summer-flowering plants is required, a start should be made at once to secure the necessary stock of cuttings. Some difficulty may be experienced in getting cuttings from some of the better varieties, owing to the cold weather we had in the early summer. If that is so, the flower shoots should be cut over, and in a very short time they will throw up quite a number of young shoots. These, if carefully managed, will root up to the end of the month. Although Pentstemons will root freely in a cold frame, it is important that they should be kept close for at least three weeks and shaded on bright days.

The Rock Garden.—During the early part of next month the rockery will require almost daily attention. It often happens in the stress of work that some of the smaller-growing plants have been crowded out by stronger-growing ones and are inclined to be lost sight of. Examine carefully a portion each day, removing the intruders that are smothering the weaker ones, and it is more than likely that the latter are almost exhausted for the want of moisture, owing to the position they occupy in the rockery. Continue to save seed of such as are required for increasing the stock. Such lovely specimens as the *Ramondias* cannot be too numerous, and in consequence all likely seed-pods should be secured.

The Hardy Fruit Garden.

Red Currants.—As soon as convenient after the crop has been gathered, the young growths should be shortened and the tops of the bushes thinned out so that light and air may reach every part of the bush. Carefully hoe and rake off all weeds and rubbish, and if the bushes are old, the surface should be mulched with some good farmyard manure.

Early Pears.—It is important to remember that some of the early varieties, such as Clapp's Favourite and Jargonelle, should be sent direct to the table, as these do not keep if stored. It will, therefore, be necessary to go over these varieties almost every day and gather those that are ripe. The best way of testing them is by lifting up the fruit, and if it comes away easily it is quite fit to be gathered; but on no account gather these early Pears until they are ripe.

Wasps.—A thorough search should be made for the nests, and have them destroyed by cyanide of potassium, as previously advised. Strange to say, it is at this late season that most destruction is done, not only among choice Pears outside, but among the equally choice Muscat Grapes under glass. Bottles containing sweetened beer will be found good traps.

Fruits Under Glass.

Late Grapes.—The later varieties will now be colouring, and it will be as well to have some warmth in the pipes, so that the top ventilators can be kept open during the night. Should there be an excessive rainfall, it will be necessary to protect the outside border to prevent the berries from splitting. Where this is at all possible, there is nothing better for this purpose than sheets of corrugated iron laid so that the water will drain away from the house.

Melons.—As this late batch comes into flower, no time should be lost in getting one or two fruits set on each plant. To ensure a quick growth, all laterals and surplus growths should be kept well pinched out. Guard against too much moisture at the roots, which would encourage canker; if this should be present, apply some lime to the affected part and ventilate more freely.

Hopetoun Gardens, South Queensferry, N.B.

ROSE-GROWING IN TOWN GARDENS.

IN these troublous days the national anxiety is likely to affect one's interest in the Rose garden, but to those whose part it is to remain behind, where brooding can afford no benefit, it is a relief to turn the mind to an occupation both beneficial and inexpensive. In the ordinary way many would now be leaving for holidays, and when this is the case it is necessary to have the plants in a well-cared-for condition before going away.

There is not a great deal which requires to be done, for at this period aphides have almost ceased to be troublesome, and caterpillars are met with less frequently. First and foremost, the trees should be carefully sprayed at least twice during the week before they are left, on the last occasion as near as possible to the time fixed for departure. Secondly, unless it is desired that others shall have the flowers while the grower is away, it is better to cut all the buds that are showing colour, as these will be littering the beds on his return, and their removal will assist the plants in forming stronger growths for autumn flowers. Lastly, the beds should have a final hoeing.

Now, while the colour effects are still apparent, is the best time for planning alterations in our Rose-beds. Many faults may be seen at present which in winter-time, with only our plans or labels to remind us of them, are apt to be overlooked. Where there have been, as sometimes happens, several failures together, one must endeavour to trace the cause, so that a remedy may follow. Occasionally one finds that certain beds are not favourable, and the reason may not be apparent until these are examined and dug over in the autumn. Insufficient drainage, want of lime, or soil that is too light, are among the most frequent causes of failure. But what will suit one variety quite well in the way of soil may prove detrimental to another that is equally free growing. A town grower must learn to recognise his limitations, and it is a wise plan to avoid giving up valuable space to those kinds which "might do better another season." If a fair start has been given them, Roses which will do well in his garden should already have proved their vigour of growth, if not their freedom in blooming. Those that have gone back or are otherwise unsuitable should stand condemned.

Every grower of Roses would delight in budding his own trees if only the means were at hand. Those who have space to spare for it should obtain a few Briars from a nurseryman during the winter months, but many are unable to find room for them. Possibly they might find enjoyment in trying just one or two, and it is not usually a difficult matter to find a spare corner at the back of a Rose-bed where these might conveniently be placed.

Briars for next year's budding may be obtained easily enough by planting an occasional "sucker," selecting those from dwarf plants preferably, as these can generally be put in with the root forming quite near the surface. It is not advisable to try to rebud standards which have failed, because the trouble is usually at the root, and a second attempt is as little likely to succeed as the first; but those who can bud successfully may have much better standards by planting the Briars and allowing them to remain undisturbed where they have been.

P. L. GODDARD.

TRIAL OF VIOLAS IN SCOTLAND.

DURING the years 1912-13 the Royal Horticultural Society made extensive trials of Violas in their experimental grounds at Wisley, Surrey, and the floral committee of that society made such awards to these plants for bedding purposes as seemed to them desirable. It occurred to Mr. Robert Fife of Messrs. Dobbie and Co., Edinburgh, that it might be desirable to have a repetition of these trials in Scotland for the purpose of ascertaining whether the characteristics of the various varieties shown in the South would be maintained in the North. Messrs. Dobbie and Co. accordingly put themselves into communication with the various growers who had sent plants to Wisley for trial, and the result was a whole-hearted co-operation to make the Scottish trial a success. The major portion of the Violas were contributed by Messrs. Dobbie and Co., and the firms who were good enough to offer their assistance were Messrs. William Artindale and Son, Sheffield; Messrs. Dickson and Sons, Newtownards; Messrs. J. Forbes (Hawick), Limited; Messrs. James Grieve and Sons, Edinburgh; Messrs. Lister and Son, Rothesay; Mr. W. H. Morter, City Gardener, Birmingham; Mr. Charles Turner, Slough; Messrs. R. Wallace and Co., Colchester; Mr. B. Wood, Liverpool; and Mr. G. Wood, Hawick, who all supplied the plants for trial free of charge. Altogether there were 229 varieties on trial.

The Violas, six plants of each variety, were planted early in April, and on the whole have made very satisfactory growth. Some old favourites, however, have not done so well in the trials as might have been expected, although in the ordinary nursery beds adjoining they appear in their usual good character. This would seem to show that to get a proper test a two years' trial, such as that conducted at Wisley, is absolutely necessary. The judging of the varieties took place on August 7, and the committee appointed was a particularly strong one, including such gentlemen as Mr. D. King, nurseryman, Edinburgh, president of the Scottish Horticultural Association; Mr. James Dobbie, a vice-president of the Scottish Horticultural Association and Superintendent of Public Parks and Gardens, Leith; Mr. Charles Comfort, The Gardens, Broomfield, Davidson's Mains, Midlothian, past president of the Scottish Horticultural Association; Mr. James Grieve, sen., Redbraes Nursery, Edinburgh, a well-known Viola authority; Mr. Matthew Todd, florist, Edinburgh, past president of the Scottish Horticultural Association; and Mr. James Whytock, head-gardener to the Duke of Buccleuch, Dalkeith, past president of the Scottish Horticultural Association. The following awards were made, * indicating the highest quality of bedding varieties, and † the next best for that purpose:

White.—* Mina, Swan, Virgin White and Alexandra. † Countess of Hopetoun, Purity, Queen of Whites and Snowflake.

Cream, sulphur or primrose.—* Lady Knox, Margaret Wood and Primrose.

Light yellow.—† Ardwell Gem and Greivii.

Deep yellow.—* Bute or Bute Yellow, Moseley Perfection, Queen's Park, Redbraes Yellow and Mrs. C. B. Douglas. † Lord Elcho, Kingcup, Royal Sovereign, Sunshine and Lizzie Paul.

Light blue.—* W. H. Woodgate. † Buxton Blue and Perdita.

Blue.—* Dairymaid and Royal Scot. † John Young, Mrs. Maclean and Ralph.

Mauve, lilac or heliotrope.—* Bridal Morn, Mrs. George Wood, Maggie Mott and Dumbryan. † Fred Williams, Kitty Bell, Mrs. Norris-Elye and Tottie.

Purple and purple-violet.—* Archie Grant, Eminence and Jubilee. † Rosy Morn.

Crimson.—* Arabella, Crimson King and J. B. Riding. † Amy Barr.

Rose or pink.—* Lady Clonbrock, Maid of Lorne and Tom Wilson. † Mrs. J. H. Rowland.

Edged.—* James Pilling, Harry Bamber, Waverley, Agnes Kay, Annabel Lee, Colonel Plumer and Jessie. † Thomas Bell, Mrs. Chichester and The Mearns.

Bronze.—† Bronze Kintore.

Violetta.—* Compacta alba, Lyric, Princess May, Violetta and White Dot.

Gracilis.—* Lutea and Purple Robe.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

DISEASE AMONG SWEET PEAS (Rosella).—The Sweet Peas sent are attacked by the wilt disease, due to the fungus *Fusarium vasinfectum*. No cure is known for this disease, and preventive measures should be taken another year in the direction of planting the Sweet Peas on a different site, liming the soil well, and giving a dressing of sulphate of potash. Flowers of sulphur dusted on to the soil might check the spread of the disease.

SWEET PEA STEMS FOR EXAMINATION (An Old Subscriber).—Sweet Peas usually suffer most from the root rot where the soil tends to hold water or is rich in organic matter. Those you send are badly attacked by the fungus *Thielavia basicola*, which is the cause of the trouble. See reply to "Rosella" for preventive measures.

POTENTILLAS (E. B. A.).—The genus *Potentilla* is a somewhat extensive one, and many species are of botanical interest only. Some of the indispensables are alba; alpestris, yellow; rupestris, white; Tongel, orange and crimson, one of the most charming; argyrophylla atrosanguinea; hopwoodiana, yellow, buff and carmine; nitida, pale yellow; Miss Willmott and Gibson's Scarlet, the finest of the red shades; and villosa, bright yellow. Apart from these are the hybrids of the florists' set, most of which are very free and profuse flowering. *P. chryso-eraseda* is a form of aurea. The other kind mentioned is not known to us.

TREES AND SHRUBS.

TREATMENT OF OLD HOLLY HEDGE (*M. P., Surrey*).—Your old Holly hedge should be clipped each year about the end of August. It is a good plan to remove all dead leaves from the hedge every few years. They may be shaken from among the branches by the aid of a stout stick and then raked up. After clearing away the leaves, give a good surface-dressing of well-decayed manure. A good watering with cow-manure water or fish manure dissolved in water may be given with advantage in May or August each year. Where dead places occur, remove the plants and as much of the old soil as possible; then fill the hole with good soil and repair the hedge with new plants in May or September.

ROSE GARDEN.

BLACK SPOT (*Taunton*).—The Rose is attacked by the fungus *Actinonema rosæ*, causing black spot. It is a troublesome disease to combat, but we think the best results are likely to be obtained by frequent spraying with Bordeaux mixture.

ROSE ALBERIC BARBIER (*C. E. F. M.*).—We have never known this Rose to sport. Probably the stock upon which it is budded had been previously budded with another kind. Your description sounds like that of *Diabolo*, and if you can send us a piece of growth and bloom, we could perhaps tell you definitely.

IMPROVING COLLECTION OF EXHIBITION ROSES (*R. E. T.*).—Of your list we should strike out *Lady de Bathe*, *Mrs. James Welch*, and perhaps *Melody*, as it is scarcely large enough for exhibition, and add instead *Mayflower*, **Ferniehurst*, *General-Superior A. Janssen*, *Mrs. E. Alford*, *Mrs. Wallace H. Rowe*, *St. Helena*, and **Heinrich Munch* or *Geoffrey Henslow* (*H.T.*). Those marked with an asterisk are not specially free blooming, but are fine, big Roses.

THE GREENHOUSE.

PRIMULA JAPONICA (*L. A.*).—Obtain and sow the seeds at once either in pans or boxes placed in a cold frame, where comparative darkness and uniform conditions would be assured. The species is of a moisture-loving nature, and the seed-pan should not be allowed to become dry. Fresh and good seeds usually vegetate freely and quickly. The firm you name would supply the seeds.

FERNS IN BOXES (*E. J. T.*).—Your better way will be to plant the Ferns in the boxes rather than to plunge the pots therein. Of course, there must be holes bored in the bottom of the boxes for the purpose of drainage, and over these should be placed a layer of broken crocks with the same object. The soil should be made up of equal parts of loam and peat, with a good sprinkling of silver sand. Suitable Ferns for such a purpose are *Adiantum decorum*, *Asplenium bulbiferum*, *Cyrtomium falcatum*, *Onychium japonicum*, *Osmunda palustris* and *Pteris cretica albo-lineata cristata*. We should not advise you to face the boxes with virgin cork, as it would afford such a harbour for insect pests of all kinds. Furthermore, you may, if you wish it, employ some plants of a drooping character, in order to drape the fronts of the boxes. Subjects suitable for the purpose are *Selaginella kraussiana*, *Panicum variegatum* and *Tradescantia zebrina*. The best time to plant your Ferns and the other things named will be in the spring.

TULIPS FOR CUTTING AND CONSERVATORY (*L.*).—Your question is somewhat vague, as you do not say if you wish to have the names of the ones for cutting grown under glass or outside. We take it you mean the latter. For conservatory decoration we recommend as singles *Vermilion Brilliant*, *White Hawk*, *Prince de Ligne*, *Mon Tresor*, *Prince of Austria*, *Rose Luisante*, *Couleur Cardinal*, *La Remarquable*, *Jenny and Wouverman*; and as doubles *Murillo*, *Schoonoord*, *Couronne d'Or*, *Safrano*, *Gladstone* and *Salvator Rosa*. To prolong the season these must be brought into heat in batches. Many lists divide the Tulips up into early and late flowering, so it is well to consult these so as to know which to bring in first. For cutting out of doors, nearly all varieties are suitable. Among the Cottage set, *retroflexa*, *Picotee*, *La Merveille*, *Mrs. Moon*, *Moonlight*, *Scarlet Emperor* and *Pride of Inglescombe* are among the best, and would give a succession of bloom. In the Darwin class there is very little to choose, as their general habit is so much alike. It depends on the colours that are wanted. The following six have good long stems, and are varied in colour: *Clara Butt*, *Euterpe*, *Fra Angelico*, *Pride of Haarlem*, *King Harold* and *Baronne de la Tonnoye*. As they are all cheap, they can be bought more largely than the expensive ones, and we feel sure will give satisfaction.

FRUIT GARDEN.

SMALL APPLES (*Hants*).—The little Apples are far too immature to enable us to identify the variety. The spots on them are due to the attack of the scab fungus. Spray now with half-strength Bordeaux mixture, and in the autumn prune out thoroughly all the diseased shoots you can find.

NECTARINE WOOD FOR EXAMINATION (*E. K. T.*).—The appearance of the piece of Nectarine wood sent suggests the tree is probably suffering from an attack of silver-leaf, due to the fungus *Stereum purpureum*. The leaves, if this is the case, would have a distinct silvery appearance, and when a tree is attacked it rarely recovers, and should be rooted out; but before you do this, perhaps you will send a leaf or two for our inspection.

MISCELLANEOUS.

CATERPILLARS ON BUSH FRUIT TREES (*K. S.*).—If the Currants and Gooseberries have no fruit upon them, spray with lead arsenate in the proportions recommended by the makers. If they have, pick off the caterpillars by hand.

VARIOUS QUESTIONS (*A. D.*).—1. Try dusting with lime (fresh slaked), or spray with paraffin emulsion. Do this about the second week in January. 2. The purple-leaved Plum, *Prunus pissardii*, or *P. cerasifera atropurpurea*. 3. They have been attacked by red spider. Spray in February or March, as soon as the pests appear, with an ounce of potassium sulphide in three gallons of water. 4. They are apparently becoming overripe.

PLANTING DAFFODILS (*Avon*).—The Privet is the oval-leaved variety, *Ligustrum ovalifolium*. The Shasta Daisies are varieties of *Chrysanthemum leucanthemum*. The end of November is very late for the planting of Daffodils and the other bulbs you mention, and though many are planted at that time, it is a fertile source of failure at flowering-time, for which only the planter is responsible. A better way would be to start the bulbs in pots, and put them into their positions when the Roses were planted. To keep them in the dry state would militate against success.

CRAZY PAVING (*W. G. W.*).—The stability and fixing of the stone depends upon its size, weight and thickness, and ordinarily heavy stone requires but little fixing. In the case of shallow stone or thin slabs of modern paving-stone, which is the least desirable of all, it would be better to bed the stone on good mortar and cement, leaving the joints free for plant-life. If not all were required for this purpose—whether they would be so required or not would depend upon the size of the stone—the stones could be arranged so closely that very little soil space would remain, and little inconvenience would be caused therefrom. We recently published an illustrated article on paved walks, but it concerned the correct planting more than the point you raise. We should only use cement for the joints in extreme cases.

TREATING A GARDEN (*New Recruit*).—Gardener No. 2 has given you the better advice, though it is highly probable that a garden which has so long remained uncultivated will take two or three years to get it into really good condition. Sandy soils usually are also hungry, and will take quantities of manure, and you might easily double the quantity of basic slag recommended and also that of the lime with advantage. Trench and manure the land as recommended, and apply the basic slag to the surface when that work is done. A little later on fork in the basic slag, and in early February apply a dressing of short manure to the surface and fork it in about a foot deep. You might apply a dressing of lime at the time the trenching is done, and another in the early part of the year, using about a bushel to each two rods of ground. You might apply a dressing of basic slag to the lawn in the autumn, and in spring a little nitrate of soda to encourage a freer growth.

SOCIETIES.

HIGHCLIFFE GARDENERS' ASSOCIATION.

ON Monday, August 10, Mr. G. Garner read a paper on "The Advance of Horticulture in the Twentieth Century." There was a good attendance of members. The lecturer gave a summary of the special work done of late in connection with horticulture generally, dealing with the development of artistic features, rock, alpine and water gardens, the herbaceous garden, the Sweet Pea, the Perpetual-flowering Carnation and other kinds of flowers now so prominent in our gardens. He also referred to scientific research, vegetables and fruits. In regard to the latter, he deplored the fact that so little advance had been made in regard to hardy fruits in orchards. There was a keen discussion by the members of the chief points raised, of the social position of gardeners and of their future prospects.

THE EDITOR'S TABLE.

A Blue-Flowered Plant from Bedford.—A correspondent who uses the initials "B. B." very kindly sends a flowering spray of *Cynoglossum amabile* from Kempston Hoo, Bedfordshire. This is a very charming plant, worthy of every encouragement, and has a more branching habit than other species that we know. Our correspondent writes: "I am sending a spray of *Cynoglossum amabile* in case you may not have seen it. It is, I believe, a new importation from China. Seeds were sown under glass last autumn, and the plants put out in the open border in May. Seeds were also sown in January, but these plants are not yet in flower. Though the individual blooms are small, the effect of the

branching sprays is very pleasing, and the colour is a good clear blue. Each plant has five or six sprays, mostly larger than the one I send. The height is 2½ feet. Seed seems to be setting very freely. I think this is a decided acquisition for the summer border."

International Sweet Pea Championship: Competition for the "Simplicitas" Trophy.

Owing to the Perthshire Sweet Pea and Rose Society's Show at Perth having been abandoned, the Boundary Chemical Company, Limited, Liverpool, have decided that under the circumstances the trophy will be competed for at Perth Show, 1915. The trophy for Wales at Carlisle Show, 1913, was won by Mr. T. Jones, Ruabon, and a gold medal has been forwarded to him in commemoration of the event.

Home-Grown Fruits and Vegetables.—In view of the special importance at the present time of securing that the home-grown supplies of foodstuffs are used to the best advantage in the public interest, with due regard to future requirements, the President of the Board of Agriculture and Fisheries has appointed the following gentlemen to serve as a consultative committee: The Right Hon. Sir Ailwyn Fellowes (chairman), Mr. Charles Bathurst, M.P., Mr. Charles Bidwell, Mr. H. Trustram Eve, Mr. S. W. Farmer, Mr. C. B. Fisher, Mr. E. M. Nunneley, Mr. Francis H. Padwick, Mr. George Scoby, Mr. G. C. Smyth-Richards, Mr. R. Stratton, the Hon. Edward G. Strutt and Mr. Christopher Turnor. The first meeting of the committee was held on August 10 at the offices of the Surveyors' Institution, 12, Great George Street, Westminster, to which address any communications may be sent to the joint secretaries.

Distribution of Surplus Plants.—An appeal to horticulturists, both owners of private gardens and market growers, is being made by the Board of Agriculture and Fisheries to preserve for distribution to allotment holders and cottagers their surplus stocks of seedling vegetables suitable for autumn planting in the district. These seedling plants, usually destroyed after the growers' own requirements have been satisfied, might, under present conditions, prove most useful. It is suggested that the owners of private gardens should distribute their surplus plants locally, either direct or through relief committees. In districts in which allotments are numerous, the owners of large gardens might be able, at little inconvenience or expense, to sow during this month Cabbages suitable for planting out in October, and so provide plants for those who themselves have no facilities for raising seedlings. Timely assistance in supplying plants would largely increase the comfort of cottagers in the coming year. Market growers who may have larger stocks of surplus seedlings than could be utilised locally are invited to communicate with the secretary of the Royal Horticultural Society ("Care of Food" Committee), Vincent Square, Westminster, S.W., who have generously placed their services at the State's disposal for this work. Although there are large stocks of food in the country, it is the duty of every occupier of land to avoid waste, and by forethought and consideration of the needs of others to alleviate the hardships that a rise in the price of foodstuffs will entail.

THE GARDEN.

No. 2232.—VOL. LXXVIII.

AUGUST 29, 1914.

NOTES OF THE WEEK.

Our Planning and Planting Competition.—We take this, the last, opportunity of reminding intending competitors that September 1 is the last day for sending in Competition designs for the planning and planting of the little garden.

The Ordering of Bulbs.—To allay any anxiety that might be felt by our readers, we draw attention to the article under this heading on page 436. Shiploads of Dutch bulbs, including Hyacinths and Tulips, are already on their way to England. Early Hyacinths and Narcissi, forced for winter flowering, are largely obtained from France, and most of the English wholesale dealers have been able to secure ample supplies.

A Good Floral Combination.—When visiting a small garden recently, we were interested in a large group of the white Phlox Tapis Blanc, about one foot high, among which were mixed good plants of Lobelia fulgens Queen Victoria. The rich red flowers of the latter made a striking contrast to those of the Phlox, and an effect so easily obtained is worth recording for future use.

Blue Bonnet (*Scabiosa caucasica*).—This hardy herbaceous perennial is the largest and most handsome of the genus. Its large lilac blue flowers, which are 3 inches in diameter, are borne singly on long stems. It is of easy cultivation. The flowers, produced with freedom at the present time, are excellent for cutting purposes; they are of a soft, pleasing colour, with a graceful appearance, and last a long time in water. There are several beautiful varieties, of which *S. c. alba*, *S. c. magnifica* and *S. c. perfecta* are among the best.

The Value of Hardy Fuchsias.—Few plants can equal the hardy Fuchsias for giving a bold effect with so little trouble. As an isolated bed on the lawn or for massing in the wilder parts of the garden, they are all that can be desired. They commence flowering early in the summer and continue till well into the autumn. A large bed we have in mind has plants of *Gaura Lindheimeri* growing among the Fuchsias and is attractive most of the summer and autumn, the light, graceful branches of white flowers of the *Gaura* rising above the Fuchsia in a most attractive manner.

A Free-Flowering Adam's Needle or Spanish Bayonet.—A bold clump of *Yucca flaccida* continues to flower on a rocky bank in the Royal Horticultural Society's garden at Wisley. Here it is seen flowering to advantage, as it is not cramped for room and the spikes of bloom are shown up against a dense leafy background. This plant is of more slender habit, and certainly more profusely flowered, than the better-known *Y. filamentosa*, of which it is sometimes considered a variety.

THE NOBLE YUCCA FLACCIDA NOW FLOWERING AT WISLEY.

The Evening Primrose as a Cut Flower.—The value of the Evening Primrose as a cut flower is not sufficiently known. On the growing plant the flowers close and droop in sunlight and bright daylight, but in the shade of a room they remain all day in an open state, and nearly as good as on the growing plant in the early morning and evening. The other day we were admiring a tall glass filled with the beautiful *Oenothera lamarekiana* and a blue *Eryngium* or Sea Holly, and the two formed an

effective combination. Although they had been cut nearly a week, they were still looking quite fresh.

Increasing Anchusas.—For the most part these effective blue flowering plants will have passed out of flower. Any time after this date the old stools may be lifted and the thickest of the roots cut into lengths of about five inches (as is done with Seakale). Lay these in boxes of sand and winter them in a cold frame, when by springtime they will have formed crowns. Seed

sown germinates freely, but the colour varies so considerably that the root cuttings are generally supposed to be best. The varieties *Pride of Dover* and *Opal* have been much admired this year.

New Sources of Potash Manures.—This country's supply of artificial potash manure comes almost entirely from Germany. The existing stock is very small, and no further importation is possible for the present. The chief natural sources of potash immediately available are (1) seaweed, and (2) weeds, prunings, hedge clippings, brushwood, leaves and vegetable refuse generally. Seaweed is already extensively used as a manure on the coasts. All who have access to this source of supply should collect it in quantity. Broad weed may be used direct as manure. Grassy weed and tangle should be dried and burnt wherever possible. A ton of fresh weed should yield 20lb. to 30lb. of potash (enough, for example, to manure from a quarter to half an acre of Potatoes).

Mignon Dahlias.—In many cases there is a stunted or unnatural look about "dwarf strains" or "dwarf sports"; witness, for example, a "Cupid" Sweet Pea or "a dwarf *Antirrhinum*." In the Mignon Dahlias which are planted in Messrs. J. Cheal and Sons' beds at the White City, there is nothing of this uncanny appearance. They look just as natural as "fairy" Roses, and might be, like them, a distinct species. They are compact little plants, about eighteen inches high, and bear well-proportioned, single flowers. The following varieties appealed to us very much: *Pembroke*, a nice clear shade of lemon; *Agnes*, very bright crimson, tending to magenta, but quite a pleasing colour; *Niveus*, white; and *Lancer*, good bright scarlet. They would make most useful fillings for the front rows of herbaceous borders.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

An Appeal to Gardeners.—May I appeal to gardeners and amateurs who possess surplus plants of Kale, Savoys, Broccoli and the like not to waste them, but to assist in the good work undertaken by the residents of the Hampstead Garden Suburb? Feeling that there may be a scarcity of food in more crowded areas at a later date, the residents have set to work to dig the waste ground of the Suburb. They hope to have a considerable quantity of foodstuffs for distribution by these means. Parcels of plants will be made good use of, and will be gratefully acknowledged. They may be sent, carriage forward, to Mr. J. T. Marks, 18, Corringway, Garden Suburb, Hendon, N.W. I can confidently recommend this as a good cause.—CYRIL HARDING.

To Preserve Damsons or Pears for a Month to Six Weeks.—My great-grandmother's plan was to fill a large earthenware or stone jar with fruit, and after baking it in the oven, to seal the

Maman Cochet, White Maman Cochet, Mrs. E. Mawley and Charles Lefebvre. (b) Defect of the kind mentioned is very seldom seen in Melanie Soupert, Leslie Holland, Edward Mawley, Dean Hole, British Queen, Molly S. Crawford and Maréchal Niel; (c) while a large number seem liable to produce a divided bloom at any time of the year. You will notice that in the second group (the more uniformly good blooms) there is a looseness of arrangement in the petals, and in the first group the petals are much more tightly folded. Is it due to changes in temperature? The cause must operate at an early stage. Can it be due to wind bruising or twisting the infant buds?—R. F. C., North Devon.

Coprosma baueriana variegata.—This greenhouse shrub is not met with to anything like the same extent that it once was. Very few, if any, subjects have the variegation more clearly defined than this, for which reason it forms a very pleasing feature in the greenhouse. It used to be largely employed for summer bedding, but is now not often seen. This Coprosma is not at all difficult to strike from cuttings of the young growing shoots if care is taken not to let them flag before they are

when in full growth, leaving unsightly blanks in the beds. The newer strains are a vast improvement upon the original. The growth is dwarf, compact and exceedingly floriferous, while the colours are very varied. The bed illustrated consisted of the Triumph strain, with a border of Blue Gem. The colours of the Triumph strain were very beautiful, and hardly any two plants were alike, yet all harmonised well. Blue Gem, seen from a little distance, looked wonderfully like very good Forget-me-nots. This bed was in my own garden, and I can safely say no bed of flowers ever gave me more satisfaction. The plants stood well in both dry and wet weather. Rain certainly spoiled the blooms for a time, but a few hours' sunshine brought out a fresh crop, and the effect was as good as ever. I do not think any other annual could give such a beautiful and lasting effect as do these new Nemesias, and those who have not yet given them a trial should make up their minds not to let another season pass without trying a bed of them. I may add that out of the large bed shown in the illustration I do not think one plant failed.—J. DUNCAN PEARSON, Lowdham, Notts.

Lewisia Howellii as a Moraine Plant.

—Having been much interested in your note in the issue of THE GARDEN for August 8, page 400, on *Lewisia Howellii*, I write to ask whether any of your correspondents can say if it is unusual for the above to flower twice during the summer? My plant, which was bought in March, 1913, did not flower that year. I covered it with glass to keep the crown dry, but admitted plenty of fresh air all round during the winter. The glass was removed early in April, and the flower-spikes began to push out immediately. There were thirteen of them on the one plant. They grew about a foot high before the buds unfolded, and each bore about forty flowers. The stems were somewhat recumbent, and formed a perfect crown of flowers. The flowers were very attractive to hive bees, and I was able to secure a good

NEMESIAS OF THE TRIUMPH STRAIN, EDGED WITH BLUE GEM, IN A MIDLAND GARDEN.

jar and bury it in a cool, shady place in the garden (about a foot below the surface of the soil) till it was required for use (after all the freshly gathered fruit was finished). The disadvantage of this method was that, when the jar was opened, it was necessary to use the fruit immediately, else it soon fermented. Bergamot Pears lend themselves well to this treatment, also Bullace Plums. One year, when there was a hard frost before Christmas, we could not dig up the jars, and after that experience we took to bottling our fruit in the way I have previously described.—ANNE AMATEUR.

Roses with Divided Blooms.—Autumn blooms of several varieties show a fair proportion of this defect. In my collection W. R. Smith is never free from it. How many blooms in exhibition stands of first merit show divided blooms towards the end of the day—even "silver medal" blooms in the autumn show! I cannot help thinking that there must be some definite cause, and that great credit will accrue to the discoverer of it. (a) In my small collection of 150 plants the following very seldom give a perfect bloom: W. R. Smith,

inserted into the pots of soil. If they flag, the action of rooting is greatly hindered.—H. P.

The Aster as a Hardy Annual.—The Aster disease has made sad havoc among Asters treated as half-hardy annuals. Those who have had recourse to sowing the seeds in a cold frame instead of in heat have found that the result has been a considerable abatement of the disease, proving that cool conditions suit the plant best. Having myself been a considerable sufferer from the disease this season, I was greatly pleased the other day to find in the gardens of Messrs. Todd and Co., Edinburgh, large breadths of Asters in the pink of health and without a blank. On enquiring about the method of cultivation, I was told that they were sown where I saw them. These gardens are situated at Stoneybank, Musselburgh, where the soil is rather light.—C. C.

The Newer Nemesias.—The original *Nemesia strumosa* Suttonii made some stir when first sent out, and certainly it gave us a novelty in half-hardy annuals; but there were two weak points about the plant. The growth was straggly, and plants had a very tiresome way of dying off

crop of seeds. As soon as the last seeds were ripe, the stems fell off and a new set of stems began to push out. These grew more rapidly than the first ones, and now (August 11) there are eight of them flowering at a height of 6 inches or 7 inches, each with about forty buds; hence the plant is now more like your illustration and others that I have seen, being so much dwarfer than during the first blooming. It is surely one of the very best rock plants ever introduced. I may say that I grow it in a moraine bed chiefly composed of whinstone grit.—H. M. BROWN, Duns, Berwickshire. [We forwarded this letter to Mr. R. Wallace, Kilnfield Gardens, Colchester, who replies: "Our own plant, which you illustrate in your issue for August 8, ripened a good crop of seed, but is behaving quite normally, not flowering twice. It is interesting to see that Mrs. Brown's plant has also been grown largely in chips. We have not protected ours in any way, but then we are doubtless much drier here, which would give us shorter flower-stems and also render winter conditions less unfavourable to the plant."—Ed.]

VERBASCUMS IN GARDEN AND WOODLAND.

SHOULD the rise, progress and development of hardy plant gardening during the past forty or fifty years ever come to be reviewed in detail, that of plant grouping now favoured, as opposed to the heterogeneous mixtures or spottiness of earlier times, would assuredly find prominent place. To-day we know something of the commanding presence of plant grouping in many directions, and while we cannot say that, as yet, it has reached its zenith, we have had a foretaste of it sufficiently good and assuring in its results to guarantee both continuance and extension in the same direction. Now that it has come—now that plant grouping is practised in woodland and shrubbery, by waterside and in rock garden—we wonder why its coming was so long delayed, seeing that Nature everywhere speaks of it in no uncertain way. It may be seen often enough in Willow-herb or Foxglove in woodland at home; in clouds of gold or purple, as Gorse or Heather garnish in their season common or moorland; or in greater array abroad, where Nature for countless years has mobilised flower beauty or tree life in never-ending battalions—things only for Nature herself, but whose replicas, in the veriest miniatures, it is true, are possible of reproduction in not a few parks or gardens to-day. In some directions more than the thin end of the wedge of this type of gardening has been inserted, and with such excellent results that there is a demand for more.

It is in this connection that attention is directed to some excellent groupings of Verbascums (Mulleins) at Clandon Park, where much good hardy plant gardening may be seen, now with Primulas, or anon with the brilliant Anchusa or Rose, and often enough with some of those finer examples of plant life, suited to woodland or like place, as the plants we have in mind. It needs but a glance at the illustrations accompanying this article to get an idea of the effect of free grouping generally; it may be with dozens or hundreds, according to individual needs or requirements. On this point little need be said; the illustrations speak for themselves. Matters of greater import to the gardener who as yet has not tried these plants are a due appreciation of their ultimate development and the means by which such development is attainable.

In the first place, it would be well to realise that while a few of the species are of perennial duration, all for the purpose we have in mind are best regarded as of biennial duration only; that is to say, the more imposing pictures of which these Mulleins are capable are forthcoming from plants whose rosettes of leaves have

reached their fullest development from the seedling stage without a check. To achieve this, seeds should be sown either in the late summer or early autumn months of the year in a cold frame, or during the early spring months in slight warmth. In each case the seedlings, as soon as they are large enough to handle, should be transplanted either into pots or boxes, and as early as possible got out into their permanent places in the garden. There are no difficulties attending their cultivation—this, indeed, is of the simplest nature—though their ready response to a generous treatment is perhaps insufficiently recognised. Not a few of the hardy plant specialists grow

yellow and bronze. More recently still—during the summer of the present year—an entirely new and welcome shade of rose colour—Warley Rose—has been certificated, the new-comer destined to raise these important, easily grown subjects to higher rank and greater beauty than ever before. Already there are purple, red, rose, white, yellow of varying shades and bronzy yellow, so that in the not distant future the gardener might reasonably expect to find others of more distinctive hue of which we can but dream to-day. Those in the accompanying illustrations are handsome yellow-flowered kinds. Others of importance are the yellow-flowered giants already named. To these may be added *V. Caledonia* and *V. Thapsiforme*, bronzy yellow; *V. wiedmannianum*, purplish; and *V. phœniceum*, which, while among the neatest and dwarfest, is one of the earliest to flower. In large degree the plants flower in June and July, some extending to August or even later.

E. H. JENKINS.

VERBASCUM CHAIXII, THE NETTLE-LEAVED MULLEIN, IN THE WOODLAND AT CLANDON PARK.

these plants freely in pots, and in this way they are available for planting out over a longer period. The giants of the race, all yellow-flowered, *V. olympicum*, *V. pannosum* and *V. vernale*, may be anything from 4 feet to 8 feet high, the measure of their stature being also the measure of the treatment, generous or otherwise, they had received from the start. Some, like the first two named, form spreading rosettes of leaves whitish or woolly quite near the soil, the rosettes in their fullest development reaching 2 feet or 3 feet across. For many years yellow was the predominant colour found in these plants, while of late a hybrid set has come into being, of which, I believe, *V. Caledonia* was among the first, and which combines

ing period having been prejudicial to first-rate results. We are, however, enabled to note the values of many of the new seedlings raised here. Perhaps the best of all the orange reds is *The King*, a glorious self-coloured variety of tall, robust growth, with splendid branching spikes and grand flowers. The blossoms, brilliant orange red in colour, open flat, and are beautifully placed upon the stems. The diameter of the blooms is 3 inches, and the petals are three-quarters of an inch across the narrow section. For massing, *The King* will prove a really grand plant, it being such a splendid, free grower and so many flowers open together.

The variety *Thor* is in the front rank of Montbretias, a really good acquisition to the ranks of

THE BEST MONTBRETIAS.

OF Montbretias with yellow and golden colourings there is no end. Quite a long list of standard varieties could be enumerated, but it is certain that in a short time many of these will be entirely superseded and lost to cultivation. However, the newest forms are of such superlative merit that one cannot regret the loss of the older varieties. One of the grandest of the new yellows is *Golden Ray*, a massive flower, unchallenged except by *Star of the East*, which at present ranks as the finest variety. The colour is a pure golden yellow, and the blossoms open flat, showing the beauty of the flower to the full. The stems are branching and the flowers are nicely spaced, and open well together. Growth is strong and free, and we look to *Golden Ray* becoming a very popular variety in the near future.

The present year has been none too favourable for Montbretias in the Eastern Counties, the dry weather experienced over the grow-

these charming flowers. It is sometimes known as the "Watsonia-flowered Montbretia," as its trumpet-shaped blossoms are carried upon erect spikes in the manner of *Watsonia Ardernei*. Thor reaches a height of 3 feet to 4 feet—the latter if the season is at all suitable—and its colouring, a brilliant fiery red, is very telling and attractive. It is an easy grower, and does not need staking, even if the plants are grown singly. The blossoms are freely produced, and a big grouping of this variety forms one of the most glowing features of the late summer garden. The variety is one of the many novelties raised here, and may be commended to those Montbretia lovers who want something better than Lord Nelson, Fire King, Lutetia and other brilliant-hued forms.

P. S. HAYWARD.

Clacton-on-Sea.

THE ORDERING OF BULBS.

D OUBTLESS not a few of our readers, in view of the present state of affairs, will be exercising their minds as to the ordering of bulbous plants for bedding, forcing and the usual requirements of garden and greenhouse, and mentally enquiring as to the possibilities of securing supplies. So much, indeed, might have been anticipated, and is, moreover, confirmed by enquiries which have reached us *à propos*. In view of this, and to allay any anxiety that might be felt by the thousands of our readers who delight in having garden or greenhouse gay during winter and spring, we have instituted enquiries in several directions, the results of which go to show that there is no immediate cause for anxiety. In certain instances, indeed—Daffodils and May-flowering and Darwin Tulips more particularly among bulbous plants of stately growth, consequent upon the ever-increasing area under cultivation of such things within the limits of the British Isles—there is little cause for anxiety, the stocks being large, in superb condition, and ripe for immediate distribution. Hence in these directions gardeners, among others, might well adopt the principle of "Business carried on as usual," and, by encouraging home industries, demonstrate their gardening zeal and patriotism in a single act. At such a time, too, it is well to remember the sources of our supplies of such things. Of the kinds above named, enormous quantities are cultivated in the Wisbech district of Cambridgeshire, while the districts around Bath, Nottingham, Kidderminster, the Thames Valley, portions of Surrey and Middlesex all cultivate these bulbous flowers on an extensive scale. Nor can we forget the part which Ireland plays, her contributions, indeed, going to swell the huge army of Tulips and Daffodils, together with many of the smaller bulbous-rooted subjects which find so much favour with the amateur in the decoration of the garden. In like manner, in the district first

named, certain bedding Crocuses, *Chionodoxas*, Anemones, Dog's-tooth Violets and others are both extensively and well cultivated, the latter invariably indicated, as in all things British, by solidity and firmness. In addition to the above, the Scilly Islands and Guernsey contribute huge quantities of bulbs, many hundreds of tons coming annually from these sources alone, and which include such delightful subjects as Freesias, *Ixias*, *Sparaxis* and others. France in her turn contributes largely of the popular Roman Hyacinth, so valuable for earliest forcing; also Polyanthus or Bunch-flowered Narcissi, Freesias, the lovely de Caen Anemones and others, some of the consignments of which are already to hand. Holland in her turn sends

example and precept and so far as circumstances permit, will they, one and all, endeavour to live up to the principle of "Business carried on as usual."

FLOWERING CANNAS.

WELL known as are the present-day race of flowering Cannas, I do not think that their merits for the decoration of the greenhouse are now appreciated to the extent they might be. We must go back to a little more than a quarter of a century for the beginning of this group of Cannas, the earlier examples of which created quite a *furor*. It was M. Crozy, then of Lyons and afterwards of Hyères, who developed the Canna as a flowering plant to an extent that was not before anticipated. As the raiser continued to put new varieties on the market year after year and others took the matter up, the list of varieties was soon a long one, and many gained recognition from the floral committee of the Royal Horticultural Society.

For the embellishment of the greenhouse they soon became popular, and to a certain extent they still remain so, although, as above noted, I do not think sufficient use is made of them. One reason of this is, I think, that the gross feeding nature of the Canna is apt to be overlooked, and those that flower well early in the season do not give us of their best later on for lack of some stimulant. I have seen plants established in 6-inch pots which were simply packed with roots. The plants gave one fine crop of blossom, after which they should have been shifted into larger pots or given frequent doses of liquid manure or some of the many stimulating plant foods now on the market. Under this treatment they will flower well on into the autumn.

Out of doors, too, the same liberal treatment is necessary, and in planting a bed, if the soil is at all dry, it is far better to fashion the bed saucer shape in order to allow water to be copiously applied. This frequent lack of nourishment in

VERBASCUM OLYMPICUM, ONE OF THE GIANTS OF THE RACE.

vast quantities of bedding and other Tulips, Hyacinths and Daffodils, to say nothing of the hosts of miscellaneous bulbous flowering subjects.

Some of the Dutch consignments are, we know, already to hand, and others are expected; though if there is a shortage at all, it might be expected from this source rather than from that of the others named, not from any lack of supplies, but from the sheer impossibility of handling the stocks at this critical juncture in Europe's history. In any case enough, we think, has been said to show that there are available at the moment very considerable supplies of bulbs of many classes calculated to make the garden beautiful, so that neither gardeners nor amateurs need stay their hand, but rather, let it be hoped, as British citizens, both by

the case of these gross-feeding Cannas may well be made a note of, as if plants that are suffering in this way are taken in hand now, a late summer or early autumn display may be ensured. We are frequently told that these Cannas may be safely wintered anywhere free from frost, underneath the greenhouse stage being often indicated as a suitable spot for them. This may be followed without question in the case of the more robust varieties, but the weaker kinds may deteriorate under such treatment. That particularly attractive section whose flowers are of some shade of yellow, dotted more or less with red, have weaker rhizomes than the others, and consequently are far more particular where they are stored during the winter.

H. P.

THE COBWEB HOUSE- LEEK.

THIS attractive Houseleek (*Sempervivum arachnoideum*), so brilliant in the summer with its glinting cobweb-like deposit stretching from leaf to leaf in a close silken veil, makes a pretty subject for some sun-baked crevice in full sun, either in the rock or wall garden. It is one of the comparatively few plants which will thrive in a position overhung by other rocks, thus protecting it from the major portion of the rainfall—provided the sunrays are not prevented thereby from falling upon it.

In time, the original plantation, maybe of a few rosettes only, develops into a curiously nummock-like form, the younger generation actually growing upon the decaying remnants of their predecessors, and eventually the whole forms a striking colony, as the illustration of a clump in my garden here at Woodford clearly indicates, while the beauty of the cushion is greatly enhanced when the mature rosettes rise for flower, gradually erecting themselves into a miniature lighthouse-like column, upon the top of which are borne the bright red star-like flowers, usually upon three to five branching sprays. Frequently, in the mountains, I have come upon portions of the rock face literally encrusted with vast numbers of these dainty Houseleeks, and there, in the torrid sunshine of the clear mountain atmosphere, the leaves of the rosettes were of a rich crimson colour, while the "web" was more brilliantly white than I have ever seen it in

this country. When we realise the fierce heat which beats down upon the plants in such a district, it is easy to understand the value of the web-like veil, which protects the infant leaves from the scorching that would otherwise be liable to occur.

In the garden the plants take kindly to almost any soil—gritty loam suiting them admirably—while if a piece of glass is placed above them from November to March, the "cobweb" appearance is retained, otherwise the excessive wet of our winters destroys it, though it reappears with returning spring. Propagation, as with nearly all the Houseleeks, is the simplest matter possible. It is merely necessary to take off some of the baby rosettes which form so freely and place them in a pot of gritty soil, using the parental ligature as an anchor, when new roots readily form from the juncture of this and the rosette itself, and the offset rapidly develops into a fresh colony.

R. A. MALBY

PRACTICAL NOTES ON VEGETABLES.

Cabbage.—The main batch of spring Cabbage should be planted without delay. If the plot on which the Onions grew is available, that affords a good site, as usually the preparation for the Onion crop is of a liberal character as regards deep digging and heavy manuring. The surface, too, will have been kept free from weeds. All that will be required for the Cabbage plants under such conditions is to draw drills with the corner of the hoe 15 inches apart for the dwarf-growing sorts like Ellam's, 18 inches for Flower of Spring, and 2 feet for the larger-growing Enfield Market. If the weather is dry at planting-time, well water the drill before planting and put in the plants with a trowel or hand fork, selecting the most sturdy plants. Plant somewhat thickly with a view to economy of space, as, when cutting

Cover this with a clean hay band and bank up the base of the plant with soil to ensure entire exclusion of light. As the plants progress, add more paper, hay and soil. Secure each plant with a stout stake to prevent it being rocked by wind, which would loosen the roots and check growth.

Celery.—Remove all side growths as they appear, restricting the energy of the plant to one stem. Continue to supply the roots required for exhibition, which are being blanched by the aid of brown paper, with copious supplies of liquid manure. By this method of blanching, the watering of the plants can go on right up to the time of using the Celery, if necessary. The main crop required for winter and spring, which is blanched by the usual soil earthing method, should be encouraged to grow rapidly by the aid of abundance of moisture at the roots, as when earthing up commences no more stimulative food can be given. From six to eight weeks are required for blanching successfully. Remove

all side growths from the base of the plants, and tie the leaves of each up straight and close together with a single piece of raffia to prevent the soil falling into the middle of the plant, which causes crooked growths. Before placing the soil about the plants, dust the surface with soot and lime, as a deterrent to slugs. Carefully chop the soil on each side of the trench and draw it carefully about the plants with the hands to a depth of 6 inches, more or less, as the length of stem denotes. The heart of the plant should not be covered. When the soil is placed firmly in position, cut the raffia from each plant to allow freedom of growth.

Runner Beans require constant attention to prolong their growth and

thus obtain a maximum crop. During dry weather give copious supplies of water to the roots; if liquid manure, all the better. Syringe the plants in the evening after a hot day. Keep the Beans constantly gathered, not allowing any to seed, as this checks the growth of future supplies.

Onions.—The bulk of the crop will be ready for lifting, which should be done carefully, remembering that bruised bulbs will not keep so long or as well as those taken up carefully. The large exhibition bulbs which have rooted deeply should be taken up with a fork, allowing the roots to die away gradually. Spread them out on a dry border until they ripen off thoroughly, turning them over daily. Should wet weather prevail, place them under cover. The ordinarily grown, outdoor-sown Onions will also be ready for harvesting. They should be treated in a similar manner, turning over the bulbs frequently.

Mushrooms.—Now is a good time to make a start with winter culture in sheds, cellars, or a

A COLONY OF THE COBWEB HOUSELEEK (*SEMPERVIVUM ARACHNOIDEUM*).

commences early in spring, if every other plant is removed, those remaining will have ample room to develop. If the Onion bed is not available, any open piece of ground will suffice, provided it is deeply dug and well manured, according to the crop previously grown there, whether of an exhausting nature or not. When planting is completed, cover the surface for 3 inches around every plant with finely sifted coal ashes, as a preventive measure against slugs, which are partial to the succulent Cabbage plants.

Cardoons.—Encourage all possible growth by well soaking the soil with liquid manure weekly. Preparation should be made to blanch the stems, which requires a period of eight to ten weeks. The aim should be to ensure clean stems free from attacks by slugs. Nothing is better than brown paper and clean hay bands. The leaves should be tied together at the top; then take a piece of stiff paper 6 inches wide and, for convenience, about a yard long, and wind it securely round the stem

DESSERT APPLE KING HARRY.

properly constructed house with a northern aspect. Collect horse-manure with a quantity of short straw and place it in a heap, 2 feet or 3 feet thick, in an open, airy shed, where it can be kept dry and the rank steam can escape. Turn it over every day for the first ten days; that which is in the middle one day should be placed on the outside the next. At the end of ten days the heat will decline, when less frequent turnings will be required, say, about every third day. When the heat is declining, the bed should be made up on the floor of the house or shed. Two feet deep and 3 feet or 4 feet wide, as circumstances permit in the shed, will make a good bed. Tread and ram the manure down as firmly as possible. The heat in the manure will again increase when put solidly together. A test thermometer should be employed in the bed, and as the temperature declines to 75°, spawning should take place. What is known as Milltrack spawn should be used, breaking up the cakes into pieces about the size of a hen's egg. Insert the pieces 3 inches deep and 9 inches apart evenly over the bed, fill in the holes with manure, and make all firm on the surface. In a week's time the bed should be covered with fresh loam, free from stones, 2 inches thick, beating it down firmly with the back of a spade. Cover the bed with hay or stable litter to prevent the escape of moisture from the soil.

Parsley.—Sow seed in a frame to keep up the winter supply. Thin the plants to avoid overcrowding, and remove the lights when the plants are established and growing freely, to be returned as the winter approaches. Plants in the open should have any decaying leaves removed and the soil frequently stirred to encourage rapid growth. For security of crop during the winter and in a locality not favourable to this plant in the open, a batch of plants should be lifted from the open and placed in a cold frame on a warm south border, where they can be protected during severe frost. Another batch should be lifted from the open and stored in soil at the foot of a south wall, protecting the plants during severe weather by boards or litter.

Spinach for winter and spring use should be growing freely. If the plants are too thick, remove the weak ones to encourage robust growth and avoid decay of the inner leaves. Keep the soil well stirred between the rows, and give an occasional dusting with soot over the leaves to clear the plants of slugs and accelerate growth.

Swanmore.

E. MOLYNEUX.

STORING THE APPLE CROP.

AT the present time the conservation of our fruit supply is of first importance. A large amount of fruit is annually wasted owing to improper storage, and frequently from improper gathering, and this point will deserve our first consideration. The whole secret of keeping fruit is summed up in the word "finish." The maximum of sun and air must be given to each specimen, and the tree must not be allowed to have more fruits than it can mature. Any overladen tree would be much better thinned even now, and the thinnings could be cooked, rather than allow a larger crop of immature fruit. Of the early kinds now coming in, it is most important to gather them before they show signs of ripeness. They will all slowly mature in a cool room. The result of later gathering will be that they are all ripe at the same time. Great assistance to the proper ripening of the fruit would be given by removing at once all side shoots which shade the fruit, and even the leaves which cover the fruit could be removed with moderation without injury, as the fruit-buds for next season are now forming. Watering with weak liquid manure for the later sorts is of the greatest assistance. It need hardly be emphasised that the greatest care in gathering the fruits and carrying them to the store must be exercised. For the later varieties, which mature about Christmas and onwards, it is vitally important that they be left on the tree as long as possible. Any fruit gathered too early will shrivel and lack quality.

A Suitable Store.—The three essentials for storing are an even temperature, a certain moisture, and darkness. These conditions are generally to be found in a cellar, and in most houses this is the most suitable place. It must not be thought, however, that without such accommodation fruit-storing is impossible. An outside shed with thick walls, or an attic which could be darkened, will keep fruit for a considerable time. The custom of keeping fruit on straw is not to be recommended, as in time the flavour is absorbed by the fruit. There is nothing better than placing fruit upon plain wooden shelves, providing they have not been newly made. The cooking varieties could be laid in heaps, and if they are late kinds they will not suffer in any way. Those who have no accommodation such as above mentioned may successfully keep the fruit in small boxes, which could be stored in any room. The boxes should be lined with moderately thick paper, the fruits laid in rows with a sheet of paper in between them. These could then be piled in any room which is not hot, and will keep some considerable time. A further method which will preserve Apples far beyond their usual season is to wrap each fruit in paper, place it in a box, and cover each layer with clean silver sand. By this means fruits of Cox's Orange Pippin may be kept quite successfully up till April, and will retain much of their flavour and crisp texture.

Varieties to Store.—The varieties for storing must be mid and late season sorts; none of our earlier Apples such as are at present on the market are of any use at all for storing. In a cool room they may be kept for a week or two, but to buy these fruits for winter use would be a great mistake. The first Apple which will be found in quantity on the market will be King of the Pippins. The fruits,

if treated as advised, can be kept till Christmas. Other sorts which are likely to be available in quantity are Ribston Pippin, Cox's Orange, Allington Pippin, Blenheim Orange and Fearn's Pippin; and of the cooking sorts, Bramley's Seedling, Golden Noble, Lord Derby, Warner's King, Bismarck, Lane's Prince Albert and Newton Wonder. Also, in the case of cooking sorts, none of the early varieties now on the market are of the slightest use for long keeping; and it may be given as a general rule that only such Apples which are marked in nurserymen's catalogues as from October and November should be used for this purpose.

Should it so happen that the autumn is not warm and sunny, the latest fruits of all may be improved by placing them in a warm room about a week before they are to be used; but given a sunny August and September, there seems every prospect that Apples will be especially well matured, and should the present low prices for fruit continue, it will be an excellent opportunity for householders to lay in a good store of the most valuable of hardy fruits.

Maidstone.

E. A. BUNYARD.

TWO USEFUL APPLES.

STIRLING CASTLE AND KING HARRY.

THESE two varieties are both early and useful. Stirling Castle is the better known, both as a market fruit and for use in private gardens. It is a certain and heavy cropper; indeed, its fertility is so remarkable that the trees are often borne down with the weight of fruit, and for this reason it is not a variety suitable as an orchard standard. As a bush or pyramid, however, it is one of the best cooking varieties in cultivation. By reason of its heavy cropping propensities it pays for severe thinning. The fruits, which are handsome and of good size, but not highly coloured, are in season from September till November. The flesh is snowy white, sub-acid in flavour, and crystalline.

King Harry is a little-known dessert variety. The fruits are of medium size, lemon yellow in colour, of crisp texture, and fine flavour. The skin is rough, rather thickly covered with russet dots. It is in season in September and October, and makes a capital pyramid tree. Very few nurserymen seem to list this variety, although it is included in Messrs. J. Veitch and Sons' catalogue of fruit trees. It is an excellent variety, and only needs to be grown to be appreciated.

COOKING APPLE STIRLING CASTLE.

THE WISLEY TRIALS.

Melons, New and Old.—From time to time trials of fruit, vegetables and flowers are held in the Royal Horticultural Society's gardens at Wisley. Foremost among the trials this year are those for Melons, French Beans and Pentstemons, the results of which have just been issued. To only three varieties of Melons have the society's first-class certificate been awarded, viz., Hero of Lockinge, Sutton's Scarlet and Frogmore Scarlet, the first two being shown by Messrs. Sutton and Sons, Reading, and the latter by Mr. Dawkins, who has recently started in business for himself at Chelsea. It will at once be noticed that these three varieties are by no means new. Hero of Lockinge, for instance, has been known for years, and we believe it to have been raised about half a century ago. It is interesting to note that an old variety still holds its own with those of recent introduction. The Melon trial was quite a representative one, and varieties, both new and old, were sent from nurserymen in all parts of the British Isles. The varieties, as in all cases in the Wisley trials, were grown under numbers, the names of the varieties and of the exhibitors being kept secret until after the judging had been completed. The Melon trial reflects the highest credit upon the cultural skill that has been given. The plants looked the picture of health, the crop was excellent, and no one could have wished for a better house of Melons. Awards of merit were granted to the following varieties: Emerald Gem and Perfection, from Messrs. Sutton and Sons; Eminence, from both Messrs. Sutton and Sons and Mr. Dawkins; Mymms Hero, sent by Mr. Hazelton; Windsor Castle, from Messrs. Barr and Sons; and Duchess of York, sent by Messrs. Dickson, Brown and Tait. Messrs. Carter and Co. were highly commended for their Amberwood Beauty and Barnet Hill Favourite, a similar award being voted to Mr. P. Davies for Sentinel and to Messrs. Robert Veitch and Sons for King George.

Awards to French Beans.—On the same occasions (July 30 and August 10) a sub-committee appointed by the fruit and vegetable committee examined the trials of French Beans at Wisley, when first-class certificates were awarded to the following varieties: Canadian Wonder (Improved), from Messrs. Barr and Sons; Canadian Wonder (Selected), from Messrs. Sutton and Sons; Early Forty-fold, sent by Messrs. Watkins and Simpson; and Perpetual, from Messrs. Carter and Co. In addition, the following awards of merit were made to Sunrise and Magpie, from Messrs. Carter and Co.; Eldorado, and Evergreen, from Messrs. Hurst and Sons, the last-named variety also being sent by Messrs. Sutton and Sons and the former by Mr. F. Simpson; and Excelsior, from Messrs. Barr and Sons. The varieties Dwarf Prolific and Masterpiece were both highly commended as pot Beans.

Trial of Pentstemons.—A sub-committee appointed by the floral committee visited Wisley on July 31, when the following somewhat lengthy list of awards of merit were recommended for Pentstemons: Lady Sybil, Gay Garland, Aldenham Pride, Persimmon, Admiral Togo, Sportsman, Fair to See, Mrs. A. C. Sweet and Virgil, all sent by Messrs. Cutbush; Rosamund, from the Lapworth Nursery Company; James Douglas, Jane Dieulafoy and Phryne, from Messrs. Barr and Sons; Mrs. Fred Fulford, from Messrs. Thompson; Margarite Baden, sent by M. Pfitzer; Crimson Gem, from Mr. E. Beckett; Alex. Wood

and President Carnot, both from Messrs. Dobbie and Co.; and Southgate Gem, sent by Messrs. Barr and Sons, Mr. W. Simpson and Messrs. Dobbie and Co.

GLADIOLI AT THE WHITE CITY.

MESSRS. KELWAY AND SON of Langport staged a magnificent collection of Gladioli at the White City on August 11. It was originally intended to display them at the Royal Horticultural Society's Hall in Vincent Square, but owing to that building being taken over for sleeping quarters for soldiers, the flowers had to seek a new resting-place. There was an immense number of varieties of the large-flowering types that are the firm's specialities, and almost all of them were of recent introduction; several were unnamed and waiting for an increase in the stock before being sent out. One was a

Measure is a most lovely yellow, the high-water mark of the firm's efforts in this direction. I remember seeing it at Shrewsbury two or three years ago and being very much "taken up" with it. I still am. There is more than a suspicion of buff in its shade. The individual flowers are large and round. One of the most pleasing of all the reds was Prince Henry of York. It is a true vermilion, not so large as many of its neighbours, but perhaps none the worse for that, as it looked as if it would stand rough weather. The attendant said it was very popular for harvest festivals. Among the others, I noted especially Vanessa, a large and handsome pink; John Churchill Craigie, an effective scarlet with pale yellow centre; Lord Alverstone, a curious mixture of scarlet and magenta, three petals being of one colour and three of the other; Masterpiece, cherry red; Nemesis, a pretty pale pink; and Kenneth Kelway, a smoky purple.

One left the exhibition feeling sorry more flower-lovers would not see it, for those in authority

A VIEW OF THE MELON TRIAL AT WISLEY, IN WHICH OLD VARIETIES COMPARED FAVOURABLY WITH NEW.

particularly striking shade of cherry crimson with bluish-looking markings or blotches on the lower petals. I believe it is to make its *début* next year as the Rev. J. Jacob. There were several beautiful whites; one, perfectly pure, called The Queen, has not yet been distributed. The individual blooms are quite round and without any markings. If I remember Europa correctly, I should say that this is a much better "thing," although it has never helped to swell a mania. Few people probably are aware of the exciting times of the Gladiolus in Holland during the last two years (1911 to 1913). Five bulbs of Meteor (now called Scarlet Emperor) changed hands for £100—£20 a bulb! I have not seen it, but it is described as a brilliant dark scarlet, extra large and beautiful. This was not among Messrs. Kelway's exhibits, but Panama, another famous mania variety, was. I liked it, but there were plenty of pale pinks as good—Lady Scott for one. This is of recent date, and a good example of this popular shade. The colour is heightened by effective little crimson blotches. Golden

told me how seriously the Declaration of War had crippled the attendance. There is behind every dark cloud a silver lining, and I prophesy that when that time comes, one of the flowers that will shine in our gardens with increasing brilliancy will be the Gladiolus.

JOSEPH JACOB.

HELENIUM PUMILUM MAGNIFICUM.

ONCE again are the golden flowers of *Helenium pumilum magnificum* attesting the value of this plant as a border flower, the shapely blooms being both pleasing in form and in colour. It is now an old plant, though many of us still remember its introduction and the pleasure with which we saw it for the first time. It is a capital plant, reaching from about two feet to three and a-half feet in height, according to the soil and the amount of moisture. In some catalogues it is said to attain a stature of 4 feet, but it rarely does this, and is more frequently about three feet. It is easily increased by division, spring being the best time for this.

S. ARNOTT

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Melon Plants in Frames require careful attention with regard to watering and ventilating to ensure a satisfactory finish. Very little atmospheric moisture will be necessary, but at the same time the plants must not be allowed to suffer from want of water at the roots. When this becomes necessary, it should be applied early in the day, and not within 6 inches of the stems. Keep lateral growths thinned sufficiently to permit light to reach the bed, and raise the fruits on small pots in order to expose them to the sun. Ventilate the frame early in the day when the weather is favourable, shutting it up early in the afternoon in order to make the most of sun-heat.

Cucumber Plants for Winter Supplies.—These should now be making good progress, and will require judicious stopping and tying in order to build up sturdy plants which will be capable of producing a continuous supply of Cucumbers through the winter. Top-dress the bed as often as young roots show through the soil, as this is the best means of keeping the roots healthy and constantly in search of food. Avoid over-cropping by the removal of all fruits beyond what is necessary for the requirements of the place.

Plants Under Glass.

Chrysanthemums.—The buds on all large-flowering varieties should be secured as soon as possible, nothing being left on the plants beyond what can be grown into large, well-finished blooms by November. A moderate amount of feeding will be necessary, but avoid giving stimulants to excess.

Mignonette.—Plants which are intended for spring flowering should be thinned to three or four in a 5-inch pot. Supports may then be placed in position, and the young plants secured with pieces of fine matting to keep them in an upright position. Remove the lights during dry weather, and syringe the plants to promote clean, stocky growth. A light sprinkling of soot may be applied with advantage during mild, damp weather.

The Flower Garden.

Border Carnations.—These may be planted out as soon as the layers are sufficiently rooted, and, to ensure the best results, the border should be trenched and a quantity of new soil mixed with it. Decayed horse-manure may be used to enrich the soil if necessary. Before planting, it may be necessary to tread the border, but only if the soil is dry enough to crumble under the foot. Allow 15 inches between the plants each way, and make the soil firm about the roots.

Tulips.—The bulbs of late-flowering Tulips should be planted as soon as they can be obtained, for, although it is not usual to plant bedding varieties before October or November, Darwin and Cottage varieties will give better results if planted a month before that time. As these will be required for cutting, the border should be thoroughly prepared at once, so that well-developed flowers may be the result. The following are good varieties for this purpose: Clara Butt, Caledonia, Duchess of Westminster, Glare of the Garden, Inglescombe Yellow, Mr. Farncombe Sanders and Orange King.

Lilium tigrinum splendens Fortunei.—This is the finest of the Tiger Lilies, and, where an autumn display is desired, will be found a most satisfactory variety. The plants grow to a height of 5 feet in good, rich soil, but in poor ground they do equally as well, although seldom over 3 feet. Some of the established plants are in flower now, but I have seen many beautiful spikes here in November from spring-planted bulbs.

Shrubberies.—Give careful attention to the thinning and regulating of plants which are likely to become overgrown, and keep the ground quite free from weeds. Plants which were shifted during the spring should receive liberal supplies of water at the roots, and in exposed positions a mulching of some kind ought to be provided.

The Rock Garden.—*Erinus alpinus*, a pretty little plant with violet-coloured flowers, abundantly

produced, succeeds well in the rock garden or on old walls. It is easily grown from seeds, which may be sown in mossy chinks or crevices in which a little soil has been placed. *Fuchsia procumbens*, *F. pumila* and *F. Caledonia* may all be propagated by cuttings now, and are valuable for planting on the rockwork during the spring, where with ordinary care they will bloom freely throughout the summer.

The Hardy Fruit Garden.

Peaches.—These should be carefully examined twice daily and the fruits gathered before they become too ripe. If hot weather continues, some part of the shoots may be allowed to remain unnailed as a slight protection from strong sun. The trees must not be allowed to become too dry at the roots while the fruits are swelling, but should be freely watered. When the crop has been gathered, many of the old shoots should be removed to make room for young growths, and the foliage may be freely syringed early in the afternoon to keep red spider in check.

Apricots.—Trees on well-drained borders should be freely watered as soon as the crop has been removed. Avoid the use of manure-water, as this may cause them to produce gross wood, which is almost certain to be followed by canker. Let the branches be thinned sufficiently to admit the sun to all parts of the trees, and pinch young growths in order to produce fruiting spurs.

The Kitchen Garden.

Lettuce.—Continue to plant out Lettuce, both Cos and Cabbage varieties, in some sheltered part of the garden, and make another sowing of hardy kinds for winter. Maximum, All the Year Round, Hammersmith Cabbage, Brown Cos and Hardy White Cos are all good for this sowing.

Batavian Endive should also be planted now for use during the winter.

Winter Greens.—All vacant ground should be filled with some green crop for use during the winter and spring. Coleworts and other Cabbage may be planted at half the usual distance apart, as time will not permit them to grow to the usual size.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Celeriac.—The Turnip-rooted Celery should now have all suckers removed from the stem. Should there be a continual spell of dry weather, it will be necessary to give the plants a good soaking, as this crop must on no account suffer from lack of moisture at the roots.

Cauliflower.—If not already done, a sowing should be made to stand the winter. It will be as well to sow in the open border, as the seedlings will be less likely to become drawn there than if sown in boxes. When the young plants are a reasonable size, they should be pricked out into cold frames, and on no account place the lights over them unless in severe weather.

Corn Salad.—The cultivation of this Lettuce is on the increase, and as the great cry is for variety, this makes a good substitute for Spinach. Sow now in drills about nine inches apart, and when large enough thin out to 6 inches.

Globe Artichokes.—As the season is now advancing when growth is not so fast, it will be advisable to go over the crop and remove all the small lateral heads. This will enable the larger ones to swell more rapidly, and on no account allow any of the heads to flower.

Onions.—Seed may now be sown. In preparing the seed-bed it will not be advisable to make the surface too fine, as it would become hard after autumn rains. Sow thinly in drills, and, as soon as the young plants can be seen, run the Dutch hoe between the rows. An occasional dusting of soot will also be very beneficial. As to varieties for this sowing, the following are very suitable: White Emperor, White Tripoli and Blood Rocca.

The Flower Garden.

Agapanthus umbellatus.—Where this handsome plant is used as specimens in the flower

garden, it should be remembered that it is a gross feeder and requires abundance of moisture at the roots. As the plants are now throwing up their flower-spikes, an occasional watering with liquid manure will be of assistance. This plant is much hardier than is generally supposed, and I have seen it survive outside during severe winters. At any rate, there need be no fear of having it planted out permanently in favoured districts.

Bedding Geraniums.—The main batch of cuttings should be secured at once, as after this date early frosts are often experienced, particularly in the colder districts. Put the cuttings into boxes and stand them outside for a time; but should the weather be wet, they had better be put in cold frames.

Propagating Cuttings.—The work of securing cuttings of the various bedding plants should be commenced at once. In the case of the less hardy, soft-wooded plants, such as *Heliotrope*, *Ageratum*, *Mesembryanthemum* and *Iresine*, they had better be rooted in a warm pit. Sometimes great difficulty is experienced in rooting a sufficient stock of *Heliotrope*, owing to the growths being so soft. To avoid disappointment it will be as well to lift some of the old plants and have them potted. They can be wintered in a cool house and introduced into heat in the spring to produce cuttings.

Plants Under Glass.

Coleus.—A batch of cuttings of this decorative plant should now be secured for the double purpose of supplying small plants for autumn decoration and providing stock for another year. Care should be exercised to see that the cuttings are not taken from plants infested with mealy bug, which would be a source of trouble later on.

Violets in Frames.—As the frames will in any case be unoccupied, it will be as well to make them up to receive the plants next month. In doing so place some ordinary Pea stakes in the bottom, over which put a covering of rough leaves. This is especially recommended in damp situations. Fork in some good loam with a little leaf-mould, and, when finished, the soil should be made up so that the plants will be quite close to the glass. Continue to remove the runners and keep the plants well supplied with water.

The Hardy Fruit Garden.

Autumn-Fruiting Raspberries.—The bushes will now require protection from birds, and to hasten the swelling of the fruits they should have a good soaking of liquid manure. It will also materially assist them if the young growths are thinned out considerably.

Strawberries.—Layers that were secured last month will now be well rooted, and should be planted in the permanent quarters as soon as possible to give the plants time in which to develop the crowns before the close of the growing season. Should this planting be intended to fruit more than two years, ample space must be allowed between the rows and also between the plants.

Black Currants.—The crop generally has been better than for some years past. The bushes will be benefited by thinning out the old fruiting branches now instead of waiting till the winter. The young growths will be better ripened if exposed to the autumn sun.

Fruit Under Glass.

Peaches.—As the trees have been cleared of the fruits, the house should be opened and the border given a good watering. If any of the trees have not been at all satisfactory, the present is the time to see what is the matter. Should young trees have grown over-luxuriantly, they will require root-pruning. In doing so open a trench about five feet from the stem and fork away the soil until the vigorous roots have been located. Cut these off with a sharp knife, and in filling up the trench introduce some good loam and mortar rubble to encourage the development of fibrous roots. This work had better be done on a cloudy day, and if the trees show signs of flagging, an ordinary garden mat may be hung up in front of them during the hottest part of the day.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

THE GARDEN.

No. 2233.—VOL. LXXVIII.

SEPTEMBER 5, 1914.

NOTES OF THE WEEK.

Abandonment of the Autumn Rose Show.—We regret to learn that the Council of the National Rose Society has decided to abandon the autumn show, fixed for September 24, owing to the present crisis.

Our Bulb Number.—A few weeks ago it was feared that there would be a shortage of imported bulbs from Holland. We now know that many shiploads of bulbs have been safely landed in this country, and we propose to devote our next issue mainly to articles on the planting of bulbs. The issue will be profusely illustrated, and, in addition, will contain a coloured plate of new Daffodils.

Do Not Neglect the Garden.—The following is an extract from a circular-letter issued by the Council of the Royal Horticultural Society:

"While rightly denying one's self all unnecessary luxuries, it is, in our opinion, an act of the highest patriotism to live our normal lives as far as possible, cultivating the same area of land, employing the same staff, transacting, in fact, all our usual business and household arrangements. To act otherwise will of necessity throw numbers of men and women out of useful and remunerative work, who, having speedily exhausted their own very slender resources, must eventually become dependent upon the Poor Rate or on the almost equally undesirable provision of indiscriminate alms-giving."

Dahlia Show at the Crystal Palace.—We are asked to announce that the National Dahlia Society's exhibition will be held as usual at the Crystal Palace on September 16 and 17, and a conference will be held in the afternoon of the 16th inst. in connection with the same, particulars of which will be issued shortly. Schedules and all information will be sent on application to the hon. secretary, Mr. J. B. Riding, Forest Side, Chingford.

Pelargonium Mme. Crousse.—This beautiful variety, with its large trusses of semi-double, rose pink flowers, still maintains its position as one of the best Ivy-leaved Pelargoniums in cultivation. It is well adapted for furnishing large vases, either in beds or on terraces, and our illustration depicts well-filled vases of this variety as they now appear near the water-side in front of the Palm House at Kew. Like all other Pelargoniums, it is readily raised from cuttings taken either now or in the spring.

Fruit-Drying in Brick Ovens.—The Care of Food Committee, Vincent Square, Westminster, S.W., issue the following advice on fruit-drying in brick ovens: Though a somewhat tedious process, drying of Apples, Pears and Plums is well worth doing by those who have brick ovens. To dry the fruit (1) Apples and Pears should be quartered. (2) Plums left whole. A layer of fruit should be placed on the lid of a wicker basket, which should be put in an oven when the fire is low at bedtime and the door left open. Take out in the morning and keep dry. Repeat nightly for a fortnight. Store the fruit in earthenware jars with closed mouths.

The Chinese Sophora Tree.—Flowering towards the end of August and during the first

hardy rock plants, and even Wallflowers and Iceland Poppies, here and there over the surface. In planting (which, by the way, is best done in the autumn) it will be necessary to introduce some soil into the crevices, and if the plants are put in while quite small, they will be thoroughly established before the spring. Where seed is sown, it should first be mixed with soil, and be so placed that it will not be washed out by autumn rains. A few plants of *Erinus alpinus* put in near the top of the wall will in the course of a year or so become established all over by seeding.

Trials of May-Flowering Tulips.—As at present advised, the President and Council of the Royal Horticultural Society have decided that the trials of May-flowering Tulips, 1915, at Wisley and of cut blooms in the Royal Horticultural Society's Hall will be carried out as arranged. Growers should send five bulbs of each variety (named) not later than November 1, accompanied by a statement as to their colour and the class to which they belong. If sent by post, address The Director, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey; if sent by rail, The Director, Royal Horticultural Society's Gardens, Wisley, Horsley Station, L.S.W.R., with advice by post to the Director.

The Cultivation of Allotments.—In the hope that the example will be widely followed, we draw attention to a movement initiated in Cumberland and Westmorland for assisting workers to add to

WELL-FILLED VASES OF PELARGONIUM MME. CROUSSE.

half of September, *Sophora japonica* is a distinctly valuable and attractive tree. First introduced from China in 1753, mature trees attain a height of 50 feet to 80 feet. As lawn specimens they form round-headed trees, usually with branches near to the ground. The leaves, which are dark green and pinnate, give the tree a distinct character. Another feature of the *Sophora* is that the foliage remains on the trees in good condition till most of the deciduous trees and shrubs are quite bare. The small, Pea-like flowers are very freely borne in terminal panicles. They are creamy white in colour, with a tinge of pink in the keel.

Planting on Old Walls.—There are many unsightly old walls about gardens that could be made attractive by planting some of the more

their food supplies by cultivating allotments. In this case members of local authorities, landowners, manufacturers, agriculturists and horticulturists have formed a committee for the purpose. Teachers of agriculture and horticulture residing in the counties, and a county land agent, have been appointed technical advisers. The County Instructor in Horticulture is secretary. Landowners are asked to provide land free of rent, rates and taxes for a year. The committee supply technical advice, organise a supply of seedling plants, provide a form of agreement, and generally take steps to ensure that any able-bodied and willing worker who has spare time on his hands may utilise it under skilled guidance in providing an additional food supply for home use.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Effective Flower-Beds.—A bed of tall standard weeping Roses of Leontine Gervaise, dotted with Rose Enchantress and carpeted with Viola cornuta, has been very pretty and the combination very effective all through the season. The Violas were planted out the first week in May, and have made a fine show from about a fortnight afterwards, and the Roses are still blooming very freely. One or two dressings of Clay's Fertilizer have been all the stimulant they have received. Anyone who has not tried this combination will be very pleased with the result. Another bed of Rose Mme. Ravary (which does well here), carpeted with Viola Maggie Mott, is very effective. The Viola, I find, helps to shade the roots of the Roses, which is beneficial.—W. A. COOK, Godalming.

Rose Hon. Ina Bingham.—Those who only appreciate perfectly double Roses or Roses in the bud stage as we are accustomed to see them at shows will not agree with me when I say that this particular variety, the Hon. Ina Bingham, when seen in its fresh, fully opened state, as I look upon it now, is one of the most beautiful of all Roses. My specimen has three perfectly formed rows of petals (deep rose in the centres and pale rose at the edges) and a glorious middle of golden yellow stamens. It reminds me not a little of the beautiful Rose Celeste, and if anything can be an improvement on that old-fashioned beauty, this is. I allow it has not the same exquisite fragrance, but it is decidedly sweet-scented. Those who like single and semi-double forms may be glad to know of this variety. In Ridgway's American Colour Chart it is rose pink and deep rose pink on Plate XII., column 71.

Blue Shirley Poppies.—Thanks to the generosity of Messrs. James Carter and Co., I have grown this summer a strain of American-raised Poppies bearing the title "Shirley Poppy—Blue Shades." It was very far from being true to name, for many white and red shades appeared. In one particular patch I pulled all these out as soon as they showed colour, with the result that I have a residue of sober, quaintly coloured blooms. They all seem to be different shades of what my American colour book calls (Plate 50, column 69) vinaceous-grays. A very appropriate name for the race would be the "Quaker strain." They are to their more brightly coloured brethren of the Poppy race what the old-fashioned Quaker ladies of a century back were to their more showily dressed sisters. A few vases with suitable green foliage in a white drawing-room would be most effective and uncommon. Iris susiana has, of course, a similar sort of colouring.—JOSEPH JACOB.

Parsley Failing.—It is a well-known fact that in many gardens there is considerable difficulty in securing a good crop of Parsley, the crop often dying off *en masse* in a few days. Various antidotes have been recommended, such as mulch-

ing the crop, applying soot-water, nitrate of soda, or dressing the ground with soil fumigants. I have tried most of the foregoing, but to very little purpose. I was told by a neighbouring gardener that he, too, had had much trouble in raising a good crop of Parsley till he planted a row of young seedlings close to the front wall of a range of glass, where I saw it thriving luxuriantly. Last spring I followed my neighbour's example, with the result that we have a better supply of Parsley this season than we have had for several years. I have frequently noticed that a stray seedling among other dwarf plants, close to the Boxwood or near a hedge or wall, thrive well when the crop in the open succumbed.—CHARLES COMFORT.

Lantana salviaefolia.—Under the name of Lantana delicatissima this is a familiar object in many parks and gardens, where it is extensively

ROSA MOSCHATA ALBA BY OPENING IN THE LARGE YEWE HEDGE IN THE SPEAKER'S GARDEN AT CAMPSEA ASHE.

used for bedding purposes. Its merits, however, as a climbing plant for the greenhouse are not generally recognised. Planted out in a prepared greenhouse border, it will grow rapidly, and soon furnish a considerable space of roof or rafter. The long, slender shoots hang down for a considerable distance, and the round clusters of flowers are produced therefrom during the whole of the summer and autumn. Under glass the flowers are a good deal paler in tint than when fully exposed to the summer sun.—H. P.

The Blue Passion Flower.—It would be interesting to have comparative experience of the hardiness or otherwise of Passiflora cærulea, the blue Passion Flower, from various parts of the United Kingdom. So far as I can learn, it has not been extensively attempted in Scotland, but I have seen plants doing well for several

years in mild parts of the South-West of Scotland. I knew a plant which grew in a Dumfries nursery for a number of years, and which flowered freely enough on the front of a wooden building used as an office. This plant was killed by the unusually severe winter of 1884-85, which was fatal to many things considered hardier than Passiflora cærulea. About the same time I lost a plant I had on a warm wall in a seaside garden, and a plant of the white variety Constance Elliot also succumbed. Other experiences make me think that it is hardly worth while to attempt to grow the Passion Flowers in the North, much as one would like to do so, though they may do in a few specially favoured places.—S. ARNOTT.

Sweet Peas: The Question of Disease.—The present offer of the National Sweet Pea Society's gold medal, together with a sum of money by that body, to the originator of a cure for that devastating disease known—for want of a more specific name—as "streak" points to the alarming extent to which the trouble has spread. So far no cure has been forthcoming, presumably chiefly by reason of failure to diagnose the cause of the trouble. A few so-called remedies have been tried, but without permanent result. My own humble opinion is, however, that the cure will not come through medicinal measures, which are at the best but palliatives. Careful observation in my own case has gradually evolved a deduction that between the rich and generous feeding—I had almost said over-feeding—and rigid disbudding and cutting down practised in order to obtain big—and often coarse—blooms for the exhibition table, together with the too rapid multiplication of new varieties, and the disease under notice there is a definite connection. Working on this thesis, the conclusion has been reached, by actual experience, that disease is somewhat less prevalent among naturally and normally grown plants than among those specially treated for exhibition purposes. To myself, therefore, the inference seems clear, and I suggest that the essential aim should be to regain possession of the plant's natural original constitution in order to replace that which has been, generally speaking, artificially obtained. This will, of course, take considerable time. Granted; but a

disease which has now been with us in a more or less degree practically since the commencement of the rise of the flower in popularity as an exhibition subject cannot be mastered hurriedly. As to the actual process of the suggestion put forward, a move in the right direction might be made by horticultural societies holding conferences on the subject, inserting appeals in their schedules, circularising their members, or in other ways offering suggestions. Many of the trade growers, too, would need approaching; and conferences of judges might be useful. To obtain a new lease of healthy life for our beautiful annual I would even suggest the elimination of competitive classes of Sweet Peas from our schedules for a time. No effort can be too great tending towards purification of the seeds and plants.—B. W. LEWIS.

GARDENS OF TO-DAY.

CAMPSEA ASHE, SUFFOLK.

AT a period such as this, when the Government of Great Britain is in the minds of the English-speaking race the world over, it seems appropriate to publish a few particulars of the gardens at Campsea Ashe, the country residence of the Right Hon. J. W. Lowther, P.C., M.P., Speaker of the House of Commons. As those who are familiar with horticultural matters know, the Speaker is very keenly interested in gardening, and it is through his personal kindness that we are able to give our readers some idea of the beautiful grounds that surround his country seat. It was a scorching hot day in July when we were privileged to visit Campsea Ashe, which is situated within a few miles of the ancient town of Wickham Market, and under the guidance of Mr. Andrews, the head-gardener, who has held the position for twenty-seven years, we spent a most enjoyable and interesting day.

Of the mansion itself, which dates back to a remote period, it is not necessary to say more than that it is situated amid spacious lawns and fine trees, so that it forms a restful resort for the Speaker and Mrs. Lowther when the relaxation of their strenuous duties enables them to take a well-earned rest. From the north entrance we find a charming view between tall Yew hedges and a beautiful avenue of Lime trees, and it may be of interest here to note that Mr. Andrews, in making some alterations last spring, found it necessary to move part of one of the Yew hedges to another position, a feat that was successfully accomplished, notwithstanding the fact that the plants were over ten feet high and of considerable age. On the west and south fronts the house has as a surround beautiful, well-kept and spacious lawns, in which stand some of the finest Cedars in the country. The tallest of these is about one hundred and three feet high, while another giant has a perfect trunk with a girth of 21 feet, 6 feet from the ground. Situated about sixty yards from the south front is a fine old Hackberry tree, *Celtis occidentalis*, one of the few that exist in this country, and near by stands, sentinel-like, a magnificent Copper Beech, a tree that any owner would be proud of. In this direction the lawn leads down to a magnificent Bamboo hedge some nine feet high and as much in diameter. This, Mr. Andrews assured us, had all been obtained from one plant of *Arundinaria anceps*, which in a subsequent conversation with the Speaker we learned was sent by his brother, Sir Gerard Lowther, from the Japanese Legation in Tokio in 1895. We doubt if there is a hedge of its kind to equal it anywhere in the United Kingdom.

On the west front the lawn leads to a very charming and well-kept oval-shaped bowling green, which is surrounded by a tall and quaint clipped Yew hedge, towering in some places to

a height of over twenty feet, part of it being shown in one of the illustrations. At the far end of the bowling green some very fine Cedars form a restful arch, and are a striking tribute to the foresight and good taste of whoever was privileged to plant them. On the right of the bowling green one comes upon two slightly sunk gardens, one consisting of flower-beds set in verdant turf and filled with blazing plants of *Pelargonium Paul Crampel*; and the other a charming Rose garden replete with rambler and bush Roses, many of them being the old-fashioned fragrant sorts that in too many places have had to give way to more modern, though less pleasing varieties. Passing along through the Rose garden and down some stone steps, the visitor comes to a charming little rock garden that owes its existence to the suggestion of Mrs. Lowther and the ingenuity of Mr. Andrews. Subsequent to the

formal garden with Lily pool in the centre, a portion of which is shown in one of the illustrations. The retaining wall is of old red brick, to harmonise with the dwelling-house, the paths being well laid with old paving-stones. Between these the beautiful little Maiden Pink, *Dianthus deltoides*, was flourishing as we have seldom seen it do, while dwarf Campanulas, *Myosotis*, *Alyssum*, Iceland Poppies, Sedums and many other kinds of low-growing plants have also been cleverly inserted so as to give a pleasing and restful effect. In the Lily pool we found a number of beautiful hybrid *Nymphæas*, such as *ellisiana*, *robinsoniana* and *odorata rosea*, just opening their first flowers as an earnest of the display that was to come later. Two broad terraced borders surround the Lily pool, the upper of these being planted with pink Ivy-leaved *Pelargoniums*, and the lower with *Heliotrope* Mrs. Lowther, a very

MIXED FLOWER BORDERS IN THE SPEAKER'S GARDEN.

Speaker taking over the gardens, this was a rough woodland corner, but now it provides a congenial home for many kinds of dwarf vegetation. *Dianthus deltoides* was doing particularly well, as were many of the choicer Campanulas, Forget-me-nots and a host of other plants. In the centre, and bordered by sandstone blocks, is a miniature pool, in which some of the dwarf *Nymphæa* hybrids were flourishing and giving excellent promise of a floral display later in the season. Under an overhanging tree a large stone slab, arched with two ancient whalebones, forms a favourite seat of the Speaker on hot days, and it does not need a very vivid gift of imagination to believe that this simple seat, set amid such peaceful and pleasant surroundings, is far more congenial to him than the more exalted and highly respected seat in another and more strenuous place.

On the left of the bowling green we find a second modern addition to the grounds, viz., a sunk

beautiful and vigorous variety that originated at Hutton John, the Speaker's former residence in Cumberland. At one end of the Lily pool, and plainly shown in the illustration, is a fine old lead tank bearing the date 1755, and on pedestals by the steps leading from the house are two magnificent bronze vases that were, we believe, rescued from obscurity by the Speaker some years ago.

Running from the east side of the mansion, the visitor finds a beautiful terrace walk under one of the finest clipped Yew hedges in the country. This hedge is over a hundred yards long, at least twenty-five feet high and over twelve feet in diameter. Bordering the other side of the walk is a long, formal Lily pond with sloping grass banks, and on the surface of the water beautiful Water Lilies nestle in abundance, while numerous carp disport themselves in the crystal water.

The old kitchen garden, which is divided from the pleasure grounds by the Bamboo hedge already

referred to on the one side and the long Yew hedge on the other, is now mainly devoted to flowers, borders of choice herbaceous plants meeting the visitor at every turn; while intersecting the various plots are Rose pergolas and pillars, supporting such excellent varieties as American Pillar, White Dorothy Perkins, Hiawatha and Rosa moschata alba, intermingled with good Clematises. By the fruit garden we were pleased to find a hedge, some eight feet high, composed of the hardy Fuchsia Riccartonii and Rambler Rose Dorothy Perkins, the two forming a very effective and pleasing combination. Rose Fellenberg is largely used here as informal hedges, and a pleasing combination, part of which is shown in the small illustration on page 442, was brought about by a large plant of Buddleia variabilis veitchianus and another of Rosa moschata alba, the lilac blue flowers of the former harmonising perfectly with the white Roses.

One might dwell long and pleasantly on the many beautiful features of the woodland surrounding Campsea Ashe, did space permit. It must suffice, however, to say that one of the best silver variegated Elms we have ever seen, a noble tree some seventy-five feet high, and a magnificent specimen of the comparatively new Buddleia Colvillei, with its large clusters of rose-coloured but unpleasantly scented flowers, are to be seen.

In the plant-houses we were charmed with a splendid collection of Show and Regal Pelargoniums, old-fashioned plants that we understand Mrs. Lowther is particularly fond of, and which we so seldom find well grown nowadays. Bougainvilleas, Orchids, Bouvardias, Lilies, Nerines and many other flowering plants are also well grown, and the fruit-houses, with their splendid crops of Muscat Grapes, Peaches, Apricots and Melons, provide excellent testimony to the skill of the head-gardener. Campsea Ashe is a place over which to linger lovingly, and those who are privileged to visit this restful spot will find more than a little that is beautiful and interesting in the charming grounds and gardens.

AMONG THE ROSES IN EARLY AUTUMN.

To have our late Roses at their best demands a little special attention now. Do not let any stale flowers or seed-trusses remain. Cut off as much as possible of the old and partly decaying foliage, as this is only too apt to retain insects and red rust. Free use of the hoe and a thorough watering are also of great benefit, and sure to pay. It is now also that mildew is more likely to appear, owing to the great changes of midday and early morning temperatures that are entirely beyond our control, and I advise a free use of the various deterrents to this disease, which will otherwise spoil the deeper-coloured foliage that

is characteristic of the autumnal growth of many varieties. Where red rust or black spot exists, carefully collect and burn all fallen leaves, also cut off any affected ones that may still hang upon the plants. One cannot be too persevering in this just now and onwards, or the germs will increase rapidly. Remedies and helps against these diseases have frequently been given, and should be followed immediately the foe appears.

A little summer pruning may be done, especially among the climbers that flower well only once during the season. It is better to cut away the exhausted wood now than to let it

VIEW IN THE SUNK GARDEN AT CAMPSEA ASHE. THE YEWS IN THE BACKGROUND ENCLOSE THE BOWLING GREEN.

continue to draw nourishment, only to be cut out early next year at the usual pruning-time. Thinning out now gives a chance for healthier and better matured growth of the long maiden rods that are of greatest service early next season. Look over the earlier-worked buds, and rebud where failures are discovered. This may be done until early September during most seasons, so long as the stock is in active growth. Some of the early buds, too, will need the ties loosened, especially if they have commenced new growth upon their own account, as several early worked buds do.

A. P.

SWEET PEA NOTES.

Autumn Culture.—The season, now fast waning, causes the Sweet Pea grower to turn his thoughts to the future, and he does so with the hope that next year's weather will be a little kinder and more congenial to the Sweet Pea than the present season has been. Certainly for the past four years the weather has not been favourable to its luxuriant growth, and the devotees of the Sweet Pea have had many anxious moments. The year 1911 was one of blazing sun and prolonged drought; 1912 followed with a sunless summer and prevailing cold winds;

the dismal weather of last year is still fresh in the memory of all; while this season has brought such a plague of green fly which, in many cases, has totally defied all efforts of extermination. Yet, notwithstanding all these adverse circumstances, a decided improvement in quality of flower has been the outstanding feature in almost every show, and one has been curiously interested in asking the methods of culture adopted by the successful exhibitors. With very few exceptions, one found that "autumn culture" was the secret of their success. I believe that comparatively few growers realise fully the value of autumn work in the culture of Sweet Peas, yet in such weather as that of this year the spring-sown plants have not had a chance. It would be well if more growers recognised that their operations would have a greater chance of success if begun earlier.

Purchase of Seed.—Many growers not only neglect to prepare their soil in the autumn, but they also postpone ordering their seeds until the early months of the year, when of necessity the supply is greatly diminished. Hence, all along, their chances of success are seriously hampered. The enthusiast, of course, has selected his list of novelties that he intends to grow next season from the exhibits of the shows he has visited, and doubtless he has likewise ordered them. Yet the ordinary grower also is well advised to get his seeds as early as possible, and the following dozen varieties (seeds of which can be procured from any firm whose name is in the advertisement columns of THE GARDEN) can be recommended: Dobbie's Cream,

Maud Holmes, Elfrida Pearson, Elsie Herbert, Etta Dyke or King White, Illuminator, King Manoel, Lavender George Herbert, Margaret Atlee, May Campbell, Mrs. Cuthbertson and Rosabelle.

Preparation of Soil.—This has been fully dealt with in previous notes, but one would reiterate that the work must be done before the winter rains make it impracticable. Again, it is absolutely impossible to over-estimate the importance of deep cultivation in relation to the conservation of soil moisture, which determines growth equally as much as, if not more than, the amount of plant food in the soil.

Autumn Sowing.—One would like to write of the many mistakes one has made, and, maybe, such an article would not be without profit, for in the growing of the Sweet Pea every mistake, duly recognised and repented of, is really a step onwards and portends future success.

The Time of Sowing is of vast importance. Seeds should not be put in too early; yet, on the other hand, unless the plants are well rooted before winter is well in, the seeds might with more profit have been kept in the seed packets. I started growing seeds from the same packet in various ways, sowing at varying periods from July onwards. Although once seeds sown in July were a success, yet unless a grower, like myself, experiments for the pleasure derived therefrom, it cannot be recommended. I record the experiment simply for its interest, and also because it is illustrative of the possibilities when soil and weather conditions are in harmony. Had the soil been a heavy clay, the plants would have "damped off." Plants from seeds sown in July were planted in well-cultivated, porous soil and cut down in September, new growths shooting up from the base. These withstood the mild winter that followed, growing away and yielding magnificent flowers in early May. However, September and October are the best months for autumn sowing, and the following plan, to my mind, is the best, and can be carried out by any grower with a fair amount of space and time at his disposal.

Planting the Seeds.—Chip all hard-skinned seeds to get a regular and quick germination, and sow in boxes or pots (I used pots) the last week in September. By the end of October the plants will be well up and able to withstand a fair amount of cold. Do not imagine that you can improve them by applying heat. The plants do not require "coddling," and will not suffer, even if frost comes, so long as they have plenty of drainage. Stand in a frame on a bed of ashes or shingle, and if they are frozen, just prevent the sun from shining directly on them until the frost is gone, and you will find that the plants thus treated will come scathless through the winter.

In January prepare a cold frame as follows: On a bed of ashes place a layer of well-decayed manure; on this put upturned turves, following with a shallow covering of about an inch of good potting soil. Into this plant the seedlings, allowing a space of 6 inches between them. You will find that the basal shoots will grow rapidly and the roots will find their way through the turves into the manure at the bottom. You will have to put small sticks to these plants, as it is important that each plant be kept separate from the other and not allowed to become entwined together. When the time for planting out arrives, it will be a very simple matter to remove the plants; the roots, having formed a compact network

in the turves and manure, will come clean away from the ash bed, and strong, sturdy plants, capable of growing right away, will be obtained. Should it be impracticable for the frame to be thus used, then it is important that all autumn-sown plants, whether in boxes of pots, should be repotted in fresh soil as early in January as possible.

Outdoor Sowing.—In gardens where the soil is light and through which moisture passes away readily in the winter, Sweet Peas may be sown directly into the soil, and they stand little or no risk of dying off, but they start into growth in the spring already well rooted and are better able to withstand the hot weather that may follow. But in heavy soil it is a mistake to sow in the open; the seedlings will "damp off" and labour is lost. The safer method is to raise the

THE ROCK GARDEN IN AUTUMN.

WHILE everyone who rock gardens at all knows that the greater flower wealth of that department is to be found from March to June inclusive, there would certainly appear to be an ever-increasing number who desire as much flower beauty as is possible during the autumn months. The desire is both legitimate and good, since, if carried into effect with as much zeal as in now displayed in the embellishing of the rock garden at other times, it would yield results that would surprise not a few. True, as already hinted, there is not a tithe of the flower beauty for the autumn months that is possible for spring, though

A ROCK GARDEN SCENE IN SEPTEMBER, WITH CAMPANULA MURALIS IN THE FOREGROUND FLOWERING FOR THE SECOND TIME.

plants in a frame and to treat them as before advised. S. M. CROW.

WATSONIA COCCINEA.

ONE of the most beautiful plants we have grown here this season is *Watsonia coccinea*, a really fine subject which I should like to commend to others. The colouring is somewhat similar to the ground colour of *Lilium tigrinum*, but is a shade more brilliant, and the black spots are entirely absent. The anthers are deep black, and, contrasting against the bright-hued blossoms, are very pleasing. *W. coccinea* with us flowers in late July with the beautiful white *Ardernei*, to which it forms a very pleasing companion. Like *Gladioli*, the corms need lifting each autumn to ensure their safety during the winter months.

Clacton-on-Sea.

P. S. HAYWARD

it is equally true that what exists is not made sufficiently good use of, and until this is brought together and utilised to the best advantage we shall never realise its worth. So far the few good autumn-flowering rock garden plants have hardly had a fair hearing. In other words, in not a few instances they have had to be content with a moderate or sparse representation. Of late, however, signs have not been wanting of a change in this direction, and the enquiries received from time to time indicate that there is a desire to extend the flowering season as much as possible, or at least to make the best use of the material which even now exists. To some extent, by an endeavour to make autumn rock gardening a feature and by planting in freer masses instead of small, isolated groups as formerly, something serviceable might be accomplished. Take, for example the genus *Campanula*, and, selecting from it such

as fragilis, isophylla in all its forms, Barrelieri, Stansfieldii, garganica in variety, Hillside Gem, Hendersonii, Tymonsii, Profusion in two varieties, to say nothing of the late comers of carpatica, we have not only some of the more showy of the rock garden Bellflowers, but also some of the more profuse flowering. Then there are hardy Heaths of importance and beauty, Crocus species in considerable variety, very beautiful hardy Cyclamen, together with Polygonums, Sedums, Colchicums, Sternbergias, Zauschnerias and others, which, if rightly employed, would go a long way to ensuring a better display than is usually seen. The thing to do in the case is to plant these autumn bloomers with the same freedom or lavishness as is done with those that flower at other seasons, rather than continue to subordinate them or permit but a meagre representation. To some extent our public gardens might assist in this direction, and where rock gardens exist, by specialising in the good things, show what is possible. So fine a Saxifrage as S. Fortunei could be made quite a feature, and if not absolutely hardy in all Northern gardens, is worthy of freer representation in many others. In certain instances recourse might be had to some of the dwarf-growing, little-known annuals, late sowings of which would provide free masses of colour at small cost. Then there are the Violettas, an invaluable race in themselves well worth specialisation, and of even greater value perhaps in Northern than in Southern gardens. Then, of course, it would be well to remember the more profuse-flowering alpine, as Androsace lanuginosa or Campanula muralis, which not infrequently provides quite a good secondary display of flowers. Lastly, the rock gardener should take note of thin carpeting subjects, and that section in particular which, having played their flower part earlier in the year, are capable of being turned to account in other ways, though best of all, perhaps, in preserving the flowers of Crocus at their time of blossoming, and over whose bulbs they may be planted with that object in view. In these and in other ways much might still be done to extend the interest of the rock garden far away into August and September each year.

THE MOURNING IRIS.

(I. SUSIANA.)

THE above Iris is perhaps the most striking of all the family, and in common with I. iberica and all the so-called Oncocyclus Irises, its successful cultivation presents many difficulties. With this plant it is true one often gets excellent results the first season, but it is only on odd occasions that one succeeds in keeping it in good health for a number of years. There is little doubt that most of our failures to keep this plant in good health are due to imperfect ripening of the rhizomes. Plenty of lime in the soil is said by some to be the secret of success; but my experience with this plant in various parts of the country has not proved this to be always the case. Other experts hold that poor soil is the secret. This I do not agree with. Good drainage it certainly must have, also a warm, sheltered position. If one can say anything definite regarding growing it successfully, good cultivation during its growing season and a regular roasting during its resting period is the method most likely to meet with success. Thus, to ensure the latter conditions the plants during their resting period should be covered with glass to keep them perfectly dry. If this is not possible, they should be lifted and exposed to the sun for a time in a cold frame, where they can be kept dry. This method, good cultivation and thorough ripening I have also found successful with the shy-flowering bulbous I. tingitana.

A good situation for I. susiana is a warm, sunny border at the foot of a south wall,

IRIS SUSIANA, OR THE MOURNING IRIS.

although in warm, sheltered positions in the South it sometimes does well in the open. Care should be taken not to plant it too deeply; in fact, the rhizomes should be no more than covered. Where it does not succeed outdoors, this Iris may be grown in pots for greenhouse decoration. The new Regelio-cyclus hybrids are very beautiful, and are apparently easier to grow than the species.

J. C.

LANTANAS.

WHILE these are troublesome weeds in many of the warmer regions of the globe, some of them, especially the garden forms, are here of considerable value for decorative purposes. They have within the last few years come well to the front for bedding out during the summer, which is not at all surprising, as they are very showy when at their best, and readily lend themselves to our varied climate. Two years ago, when so many bedding plants suffered from the intense heat, the Lantanas were in every way satisfactory, and though last season was wet and cold, they were very fine. There are a great number of varieties, one of the best known being Lantana salviaefolia, more generally known as L. delicatissima. This, which attains a considerable size, has bright violet purple blossoms. The best of the rich-coloured varieties is the deep scarlet Incendie, while Drap d'Or is a good yellow. It is not alone as bedding plants that these Lantanas are of service, for when a greenhouse has to be kept gay with flowers at all seasons they may be depended upon to give of their best, and that, too, over a lengthened period. Lantana salviaefolia is a good roof or rafter plant, whose long, slender shoots will hang down for a considerable distance and flower for months together.

GARDENING FOR BEGINNERS.

THE PROPAGATION OF SUMMER BEDDING PLANTS.

EVERY autumn a number of cuttings of the different kinds of bedding-out plants should be propagated. It is better to propagate in early autumn than late, providing the cuttings are available. We generally want cuttings and a fine display of blossom in the garden at the same time, and this is one reason why propagation is deferred as long as possible. In every instance the shoots that make the best cuttings are those that do not possess flowers, so that by judicious selection the cultivator can obtain the cuttings without marring the general good appearance of the beds of plants.

How a Cutting Forms Roots.—The cultivator should understand what actually happens after he has taken a cutting and inserted it in some soil. If he does, he will know how to treat the cuttings throughout the winter so as to keep them healthy. If, in dealing with the majority of cuttings, the stems are severed between the joints, the lower portion of the stem will decay and the cutting will be lost entirely. If, however, the stem is severed through the lower part of a joint, it will not die if properly treated, but form roots from the node or joint. If too much moisture is given, these very tender roots will perish; also, if they are allowed to remain in a very dry soil for a long time, they will gradually shrivel up and adversely affect the base of the cutting itself. No amount of moisture or care will, in many instances, result in saving the cutting. Very soft, sappy-stemmed cuttings are not suitable, because in many cases the stems would decay instead of forming a callus and roots. Very hard wood is not suitable, because

it would remain a long time without forming roots, and, even after growth commenced, the new shoots would be stunted and generally unsatisfactory throughout the next season or until the end of the next summer. With regard to the length of the cutting, it will be safe to insert one-third under the soil. Half an inch would not be deep enough to insert a 5-inch-long cutting of Zonal Pelargonium, but it would be quite deep enough for a 2-inch-long one of Lobelia or Gazania.

In Fig. A, No. 1 shows a Coleus cutting prepared for insertion. No. 2 depicts one of an Abutilon, the stem and lower leaf of which must be severed at the dark cross lines before it is ready for putting in, and any flower-buds on cuttings of this kind must be pinched off. No. 3 shows a prepared cutting of a Mesembryanthemum, and No. 4, of a Gazania. These will be sufficient to show the beginner how to proceed when selecting and preparing cuttings generally.

A.—VARIOUS CUTTINGS PREPARED FOR INSERTION.

B.—CUTTING BOXES AND PANS MUST BE MADE READY BEFOREHAND.

The Compost, Boxes and Pots.—Loam must form the chief ingredient, as shown at No. 1, Fig. B; coarse sand, No. 2; leaf-soil, No. 3. These parts should be in proportion, as depicted by the heaps. No. 4 shows the bottom of the cutting-box with holes for drainage, and strips of wood nailed across to increase the strength and preserve the bottom from decay by close contact with the ground, as illustrated at No. 5. No. 6 shows the drainage material and soil, No. 7, in a pan ready for the insertion of cuttings. All pots, boxes and pans must be prepared in a similar way. In Fig. C, No. 1 represents a cutting-box, and No. 2, the soil surfaced with sand in which to insert the cuttings. Good positions for the cuttings are on shelves and stages in a greenhouse, as shown at Nos. 3 and 4 respectively, and Nos. 5

and 6 in a frame. Zonal Pelargoniums will not be adversely affected if exposed to sunshine and plenty of air; but the majority of the cuttings

C.—IT IS IMPORTANT TO FIND GOOD POSITIONS FOR THE CUTTINGS.

will succeed best if lightly shaded and kept free from draughts.

G. G.

ROSE GRAND DUC DE LUXEMBOURG.

ALTHOUGH this beautiful variety has one very bad quality—that of hanging its head—there are few Roses that have charmed me more. It possesses such a lusty vigour and delightful habit that these alone would secure it consideration; but when we examine its colour we discover the secret of its fascinating so many individuals. It is the two wonderful colours that exist in each flower that command attention, the inner side of the petals being clear rosy pink and the outer brilliant lake. The nearest approach in colouring is Mrs. E. G. Hill, and this variety has the merit of producing its flowers erect, which makes them more decorative, yet there is lacking that vigour which we admire so much in the Grand Duc. I cannot but compare the growth to that of Viscountess Folkestone; indeed, the two would make charming companions. We are getting quite a number of Roses of these two colourings, but I think Grand Duc de Luxembourg will well hold its own. It is interesting to note how each raiser has his own special strain. Messrs. Soupert and Notting, the raisers of the Rose under notice, have issued two that bear a resemblance to Grand Duc de Luxembourg, namely, Mrs. E. G. Hill and Alberto N. Calamet; and Messrs. A. Dickson and Sons with their golden set, such as Mrs. Peter Blair, Harry Kirk and Duchess of Wellington, all bearing evidence in their growth of a kindred relationship. P

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Late Vines on which heavy crops are ripening must be freely supplied with moisture at the roots, and the ventilators left slightly open during the night in order to dispel moisture. If dull weather sets in, a little fire-heat may be employed with the same object in view. Ventilation in the early morning is of great importance to Grapes during the ripening stage, especially at this season. Lateral growth must be regulated over the trellis as evenly as possible, and never allowed to become so dense as to interfere with the proper circulation of air or to deprive the berries of the necessary nutriment to bring them to a perfect finish.

Plants Under Glass.

Lilium longiflorum.—If flowering plants are required in midwinter, no time should be lost in potting the bulbs, and as these have been retarded, they ought, as soon as they are delivered, to be placed in pots which are not too large. The soil may consist of three parts sandy loam and one part leaf-soil. Earlier plants which are showing flower-buds should be examined, and if aphides are present on the foliage, the house ought to be fumigated at once.

Lily of the Valley.—Retarded crowns of this favourite flower may be potted up now, and should be in bloom during October. The crowns must be potted as soon as they are received and kept in an even temperature, as any check in this way will be very injurious to them. A light covering of Cocoanut fibre refuse may be placed over the pots in order to keep them in an even state of moisture.

Bouvardias in cold frames should be freely supplied with liquid manure. In order to promote clean, healthy growth and, consequently, fine flowers, give plenty of space between the pots and keep the lights off during the night, as heavy dew will have a beneficial effect on the plants, providing the temperature is not too low.

The Flower Garden.

Narcissi.—If plantations of these are contemplated, the bulbs should be selected and planted with as little delay as possible, for although they will flower if planted as late as December, far better results are to be obtained by planting now. Narcissi may be grown in almost any position in the garden or pleasure grounds, and the stronger-growing varieties have a very pleasing effect when planted in grass under deciduous trees or in front of the shrubberies. In planting dwarf-growing varieties, the bulbs may be placed 2 inches deep, but for tall-growing sorts twice that depth is not too much.

Propagating Bedding Plants.—This work should be pushed forward as quickly as possible. Fuchsias, Heliotropes and similar plants may be propagated in a close, cold frame within a few inches of the roof glass. If the frame is kept close and sufficient shading provided, there will be no difficulty in securing a good stock of plants. Frequent light syringing is necessary to keep the cuttings from flagging. In selecting cuttings, long pieces should be avoided, as the best results are obtained from short, stocky tops, which strike much quicker and make better plants in the end.

Violets.—These plants should be frequently damped overhead in order to keep the foliage healthy. A light dusting of soot will also do much to keep red spider in check. Remove worthless side shoots, and as this work proceeds the crown shoots should be selected with a view to securing stock plants for the following year. If these cuttings are planted in some sheltered situation about six inches apart, they will make valuable plants ready to put out in April.

Violas ought to be cut over and the cuttings taken in October. Slight shading will be necessary until the roots take possession of the soil, after which the lights may be removed until sharp frost sets in.

The Fruit Garden.

Strawberries.—In making new plantations of Strawberries it should be remembered that these plants are deep-rooting and require a depth of 2 feet of good rich soil to grow them to perfection. When the ground is being prepared, a quantity of

farmyard manure should be incorporated with the soil, which must afterwards be trodden when moderately dry. When the plants have been put out, a liberal supply of water ought to be given, and this must be continued until the roots have re-established themselves.

Fruit Trees.—The roots must not be allowed to become too dry now, or the prospect of a good crop next season will be much reduced. Keep the breast-wood cut back to within a few leaves of the basal buds in order to mature them and encourage the formation of fruit-spurs. The leading shoots should be kept nailed to the wall to secure them against rough wind.

The Kitchen Garden.

Sowing Cauliflowers.—Now is the time to sow seeds of Cauliflowers for wintering in cold frames with a view to planting them out at the beginning of April. From these plants a good supply should be available by the beginning of June, providing suitable varieties are selected. For this purpose I find Great Dane, Magnum Bonum and Early London answer the purpose well, and come into use in the order named.

Winter Spinach.—This may still be sown, and a sheltered position should be chosen for it. If the ground is dry at the time of sowing, the drills may be watered the night previous. This will hasten the germination of the seeds by several days.

Celery.—Give liberal supplies of water to all Celery plants, and earth up early plantations as it becomes necessary. Tie the foliage with some soft material until the soil has been placed in position, after which the ties may be carefully removed.

Leeks.—The early plants will benefit by an abundant supply of manure-water. Keep the soil stirred between the plants, and earth up as it becomes necessary.

Keep the Hoe at Work among growing crops so that all weeds may be destroyed before the season is too far advanced.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Spring Cabbage.—Preparations may now be made for planting this important crop. For the earliest supplies a warm border should be selected from which early Potatoes have been gathered. To ensure a sturdy growth, simply level the ground, which afterwards ought to be made fairly firm by treading. Plant out in rows about fifteen inches apart and 9 inches between the plants. Larger-growing sorts will, of course, require more room. Guard against grubs by giving a dusting of soot and lime occasionally.

Potatoes.—Continue to lift and store such varieties as appear to be fully grown, as, if wet weather sets in, disease and scab are sure to make their appearance and cause much damage to the tubers. In storing, all diseased tubers should be carefully picked out, and small sets may be collected and placed apart, when they can be looked over and graded on wet days.

Turnips.—Although it is just late enough in most places in the North to make a sowing after this date, still, if a vacant space is available in a sheltered part of the garden, it will be worth while to sow a few rows of these, which would come in useful even if the Turnips only grow to the size of half-a-crown. With the increased moisture at this season they will come through in a few days. To hasten growth, give the ground a dusting of Peruvian Guano, and with a mild autumn they will grow on till November.

Celery.—As frost is often experienced in the North any time after this date, the work of earthing up the main crop should have immediate attention. It will be more than ever necessary at this time to select a dry day for the work, so that the soil may be reduced to powder, and care must be taken that no soil gets into the hearts of the plants.

The Flower Garden.

Begonias.—Where this year's seedlings were planted out in the reserve garden, many of them

may be lifted carefully and potted. These will bloom for some time yet and add a rich colour in the greenhouse. The remaining bulbs must be left until growth is completed.

Early Flowering Chrysanthemums.—Like the foregoing, plants coming into bloom can be lifted and potted for furnishing the greenhouse and conservatory, and thus give a supply of flowers until the pot-grown plants come into bloom. Although these Chrysanthemums are very accommodating, they must be lifted with good balls of soil attached, and be well watered and shaded heavily until they recover from the check of removal.

Plants Under Glass.

Humea elegans.—Seed of this graceful plant which was saved from home-grown plants should now be fit for sowing. Place the seed-pan in a moderate temperature, and, as already pointed out, careful watering is essential from the very start. When the seedlings are large enough to handle, pot them singly into 2½-inch pots in a mixture of loam, leaf-mould and sand. Keep the plants close for a few days until they are well rooted.

Bulbs for Forcing.—Where early flowers of Tulips, Hyacinths and Narcissi are in demand, a start should be made in getting the bulbs potted. However early they may be wanted, they must not be unduly excited at the start. After potting, place them against a wall and cover with 3 inches of sifted ashes. If the soil is fairly moist, no water will be required until they have started into growth. A number of boxes may also be filled with Daffodils from the border, Golden Spur and Trumpet Major being useful varieties for this work. Until growth commences they must be treated in the same way as pot-grown bulbs.

Carnation Souvenir de la Malmaison.—The layers of this Carnation will now be ready for potting, and great care must be exercised in this operation. Endeavour to get good balls of soil attached, and put them into suitable-sized pots. After potting, stand the plants in a good frame until they are established; but care must be taken that too much moisture is not allowed to settle on them. Should green fly make its appearance, syringe slightly with Quassia Extract, as fumigation is not always practicable in frames.

The Fruit Garden.

Pears.—Now that most of the small fruits have been gathered, the nets should be used to protect wall fruits, particularly Pears. Extra choice fruits should be supported by tying them up to the wires or branches. The same results would be obtained by using small muslin bags, but they are, to say the least of it, unsightly. Means should also be taken to guard against squirrels. They can nip off a Pear and make off with it with the most astonishing ease. We caught many last year entangled in the net.

Apricots.—As most of the fruits have been secured, the trees ought to be gone over, and any pruning necessary should be done now. Very often, when this work is delayed until the winter, a good deal of gumming results. It is quite obvious, however, that the earlier the work is done, the more good will result to the building up of next-year's buds.

Fruit Under Glass.

Peaches.—The earliest varieties will now have completed their growth, which will be seen from the plumpness of the buds. Where this is the case, open the ventilators to their fullest extent, so that the trees may have a complete rest. Trees that have carried heavy crops may still have liquid manure applied occasionally, and use the syringe only to keep the foliage healthy.

Figs.—The second crop will now be ripening, and in consequence the atmosphere must be kept somewhat drier. Any fruits produced after this date should be stripped off, as it is evident that they will have no chance of ripening. Any pot-grown trees requiring a shift should be seen to as soon as the fruits have been gathered, but guard against overpotting these.

THE GARDEN.

No. 2234.—VOL. LXXVIII.

SEPTEMBER 12, 1914.

NOTES OF THE WEEK.

Competition for Tobacco Plants.—An interesting feature of the flower show recently held at Twynholm, Kirkcudbrightshire, was the competition for Tobacco plants. No fewer than twenty were exhibited. Tobacco is being cultivated for commercial purposes on a considerable scale in the district, and much interest is being taken in the crop in the vicinity.

Bottling Pears.—The best time to bottle Pears is when they are ready to pick, as the flavour of each variety is then much more pronounced; but these are also extremely good and palatable if picked before the fruits are properly matured, which often has to be done when the trees are overcrowded. In no case should the fruits be bottled if they are over-ripe in the slightest degree.

Royal Flowers for Scottish Hospital.—By the command of Her Majesty the Queen, Mr. J. Michie, M.V.O., the King's Commissioner at Balmoral, has intimated to the managers of Morningfield Hospital, Aberdeen, that flowers from the Royal Gardens at Balmoral and Abergeldie will be sent to the hospital once or twice a week. There is no doubt that the kindness of Her Majesty will be very highly appreciated by the patients at the hospital.

The Double-Flowered *Euphorbia caucasica*.—This is an excellent plant for the herbaceous border. It grows about two feet in height, and blooms in the South of England in the early part of August. It is somewhat like a *Lychnis* in its general appearance. The flowers are double and pure white, and are freely produced. Although we were assured that *S. caucasica* was the correct name, it appeared to be very like the old officinalis with double flowers. It was, however, of a more compact habit.

Sowing Parsley.—This is one of the most valuable herbs, being in demand the whole year round; but often during the winter months there is a scarcity of it. Liberal sowings should now be made in unheated frames. Plants raised from a sowing now, and under these conditions, frequently prove very valuable during severe weather in winter. Any seedlings that are now

ready to be planted out should be put in a row along a south wall or fence, and will be found of great value later.

A September-Flowering Alpine.—In *Viola cornuta* we have a showy plant for the rock garden in late summer or early autumn, but for some reason its merits are often overlooked, and it is frequently omitted from compilations on late-flowering alpine. It loves limestone, and is very suitable for growing among rocks or in steps of rock gardens. The subject of the illustration on this page is the white counterpart of this delightful *Viola*.

VIOLA CORNUTA ALBA, A LATE-FLOWERING PLANT FOR THE ROCK GARDEN.

Planting Small Bulbs.—Where it is possible to commence this operation, no time should be lost. All bulbs benefit by early planting, particularly small bulbs, which tend to dry quicker. Snowdrops, Chionodoxas, Scillas, Fritillarias, Muscaris and other small bulbs may now be planted in places that are at liberty. Beds that are filled with summer bedding plants will have to wait, not because it is beneficial, but because it is convenient.

Hydrangea hortensis.—To obtain dwarf plants for flowering in May and June, the cuttings should be taken now. Choose strong, short-jointed

shoots which have been grown in the open. Cut them below the third joint and remove the two bottom leaves, afterwards inserting them in small pots of sandy soil and placing them under a hand-light in a cool, close pit until sufficiently rooted. They may be wintered in a cool pit with plenty of ventilation. Pot into 5-inch pots about the end of January. If grown near the glass in an intermediate temperature, they should flower within 14 inches of the pot.

Vegetables for the Troops.—The military authorities are purchasing large quantities of farm and market garden produce, including Potatoes, Cabbages, Carrots, Onions and other vegetables, for the use of His Majesty's troops throughout the country. For the purpose of facilitating supply and of preventing, as far as possible, a scarcity of produce arising in one district while there is a surplus in another, farmers and market gardeners are urged to assist the War Office by stating the quantity of produce they have to sell at fair market price. Forms for the purpose can be obtained either from any post office or direct from the Board of Agriculture and Fisheries, 3, St. James' Square, London, S.W.

An Example Worth Following.—At Chard, on Saturday, August 29, a Patriotic Flower, Fruit and Vegetable Show was held in the Corn Exchange in aid of the Prince of Wales' National Relief Fund, when a sum of £40 was raised for it. The idea originated with Messrs. Jarman and Co., who supplied all the blooms gratis. These had

been grown for show purposes; but shows having been abandoned, it was thought well not to waste them, but turn them to a good account. Prize cards only were given in the competitive classes as mementoes of the show, and there were over one hundred and sixty entries. The whole of the produce was sold for the above Fund. During the day twenty young ladies undertook to sell button-holes in the streets. The number sold was over two thousand, realising the splendid sum of £15 15s. No doubt there are many who have a quantity of blooms to sell which might be used to bring about an equally good result.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Pungent Preserve of Pears.—An excellent addition to curry, or can be used as a sweet chutney. Ingredients: Four pounds of Pears, 3lb. of sugar, 2oz. of ground ginger, the juice and rind of a large Lemon, a suspicion of Cayenne pepper, and a little water. Method: Pare, core and quarter the Pears and boil with all the other ingredients till quite tender.—ANNE AMATEUR.

Butterflies.—Allow me to call attention to a new joy for these beautiful visitors to our gardens. I refer to Buddleia Veitchii. The long, closely set inflorescences attract a variety of butterflies. I noted Peacock, Tortoiseshell, Red Admiral, Large and Small White Cabbage and Brimstone actively engaged inserting their probosces into

The Verbascums.—It is pleasant to read Mr. E. H. Jenkins' appreciative notes on the Verbascums on page 435, issue August 29, and to see the good groups shown in the illustrations which accompany the article. I am an old admirer of the Mulleins, and having cultivated some of the hybrid Verbascums, derived from V. phœniceum, for a very long time, it is particularly agreeable to me to observe the great advance made in these flowers within the last few years. I have cultivated V. phœniceum for a great many years, but somewhere about twenty years ago, I think, I observed in the seed list of the late Mr. Baylor Hartland of Cork that seeds of V. phœniceum hybrids were offered. I procured a packet, and from these seeds had some beautiful varieties of the phœniceum type, but generally rather more vigorous. One of these was the same as Caledonia, and I still have that plant in my garden. There were whites, bronzes, purples and almost lilacs, but no pure yellows. I saw

beauty. There seems to be no limit to the variety we shall have among these flowers, and the most careful selection will be necessary if we are not to be flooded with too many new forms, a large proportion of which are too much alike.—S. ARNOTT.

Help the Trade.—It is somewhat strange that, despite the very real enjoyment and interest obtained by the pursuit of gardening, it is almost invariably in the garden that at any time of financial stress the first efforts are made at retrenchment of expenditure. It is an old grievance among gardeners that employers are wont to cut down expenses and reduce the wages bill in the garden when they do not dream of disturbing the stables or the household staff. None can gainsay that at this time of grave crisis it is but reasonable—if, indeed, not absolutely necessary—that one and all should exercise economy and guard against anything approaching extravagance; but there are, happily, many in this land of ours

whose means admit of their adhering more or less to their customary modes, even at such a time as this, and it is sincerely to be hoped that they will heed the appeals that have been made and help traders, including nurserymen, to carry on business as usual. No secret need be made of the fact that, generally speaking, the nurseryman's business is one that shows its owner little more than a decent living, so that a stagnation of trade leaves no option but to reduce the staff of workmen to the lowest possible limits. The workers, even at the best of times, receive no more wages than suffice to meet the most moderate requirements, and to be thrown out of work is to be immediately thrown into a state of privation and want. It is, therefore, a matter of real importance and urgency that all who are able shall continue to support the nursery trade and send without delay orders for trees, shrubs and plants, so that nurserymen may find the wherewithal to keep going and retain their workmen. Owners of large estates will doubtless find opportunity this autumn and winter to carry out schemes of planting ornamental and fruit trees, or of

GRASS OF PARNASSUS IN A STREAMSIDE GARDEN.

the tubular flowers with evident enjoyment, thus adding new beauty to a very showy shrub. To get the plants in perfection of flower they should be cut hard in the spring. Later on, the pink Sedum spectabile is very attractive to butterflies, growing only a foot high, with dense, flat flower-heads. One autumn our Michaelmas Daisies were swarming with the Painted Lady, which is ordinarily rare except on our Kentish coasts.—GEORGE BUNYARD.

The Grass of Parnassus (Parnassia palustris).—It is interesting to note that the Grass of Parnassus, which is still flowering in many bog gardens, is in reality a native of this country, and is found wild in moist heaths and bogs. It takes its popular name from Mount Parnassus, where presumably it also grows wild, and it was called Grass of Parnassus by Dioscorides. Unlike many choice British plants, it is amenable to cultivation in our gardens. It may be increased either by seed or division, and thrives in a moist, peaty soil.—C. Q.

some hybrids at Mr. T. Smith's Newry Nurseries later, and more recently, of course, the advent of the fine hybrid Miss Willmott opened up to us a new range of Verbascums. Messrs. Harkness and Sons of Bedale have done good work with these flowers, and some of their varieties, such as International and New Departure, are splendid Mulleins. I have also had an opportunity of seeing the magnificent new Warley Rose, exhibited in London this year, which is a flower of outstanding beauty and distinctness. Another Bedale firm, Messrs. George Gibson and Co., have also entered the field as raisers of new Mulleins, and I have had the pleasure of examining some thirty new varieties raised by them. Of the yellows, Golden Glory, with a crimped edge; the large light yellow Fernandes; Aquitania, large deep yellow; and Dr. Hutchison, almost cream, were among the finest. I also noted those named The Premier, mauve and very large; Terra-Cotta, the name indicating the colour; Mauve Queen, mauve; and a number of others of much

effecting alterations and improvements in their grounds that will bring into requisition both plants and labour. The middle-class amateur gardeners will, let us hope, realise that ever so small a sum that can be spared for a few plants will be a help towards pulling through this most trying time; for it is infinitely better to so spend money that it will help to keep trade on the move than to disburse indiscriminate charity. One other thing calls for mention, to wit, a large proportion of the tools used in gardens have of late years been of German manufacture. Propagating and pruning knives, shears, secateurs and a good many other gardening requisites have been imported; but it behoves every owner of a garden to insist that articles of British manufacture only shall be used in his garden. We owe it to our fellow-countrymen and to ourselves that the money we spend shall be for the benefit of home trade and British workmen, instead of going into the coffers of those who are striving by brutal force to crush and degrade us.—HEATHER BELL.

GARDEN FRITILLARIES.

"I T hath been called Fritillarie," Gerard tells us in his "Herball" of 1597, "of the table or boord upon which men plaie at chesse, which square checquers the flower doth very much resemble."

He was speaking of our Meadow Fritillary or Snake's-head, neither of which English names can have been very common in his day, for although Lyte more than twenty years earlier wrote that the *Flos Meleagris* was sometimes called *Fritillaria*, Gerard goes on to say: "In English we may call it Turkey-hen or Ginny-hen Floure and also Checquered Daffodill and Fritillarie according to the Latine."

As a fact, however, the Latin "*Fritillus*" was a dice-box, and not a chess-board as is sometimes stated, and if dice-boxes bore a mottled or check pattern, there would be every probability that they had suggested the name for the slender-stemmed plant with its solitary upturned flower-box. Clusius says the name was given by Capperon, a druggist of Orleans.

Fritillaria Meleagris.—Less than half the known species of *Fritillaria* are in cultivation, and of the thirty or so that appear in nursery lists very few are known and appreciated as they deserve. None of them, it is true, better deserves knowing than the beautiful wilding which still maintains its place in the moist river meadows near Oxford. There can be no need to describe what everybody has or can get at 4s. a hundred. It is a plant to use in battalions and to encourage to naturalise in grass or orchard. If the soil is very light and dry, I should plant in half shade. That will also tend to give longer and more slender stems as well as more lasting flowers. But in retentive soil at Colchester it does thoroughly well in full sun, and the little colonies of about half a dozen sorts that I planted several years ago are now thoroughly mixing themselves up by throwing seeds into one another's territories. Of course, with plants that seed so freely, there are a great number of named kinds about. Parkinson knew a dozen, but I do not know that many people need more than half that number. The pure white one, *alba*, is, of course, indispensable. *Empeior* is very distinct. It has such large, broadly expanded blooms that it seems more than a mere colour form, and if I wanted to add a darker and a paler form, I should choose *F. Orion* and *F. Cassandra*. There is a very curious Fritillary that goes under the name of *F. contorta*. The segments of the perianth are in part united and the flower tapers gradually from the base to the apex, forming a long, slender trumpet in place of the shouldered cylinder of the typical *P. Meleagris*. There are white and purple forms of it, but both are very uncommon. Nicholson in his "Dictionary of Gardening" says that the origin of the plant is unknown, but I have seen it stated that it has been found wild in company with the Snake's-head, and that it is probably only a sport. If so, it is the most distinct sport I know. These common Snake's-head Fritillaries

are well worth growing in pots to provide early flowers. They are very easily grown in any cool greenhouse or frame, and few things are more graceful and charming.

F. imperialis.—The second Fritillary to mention is, of course, the old Crown Imperial, about which there is a magnificence that really demands nothing less than first place, although its smell is hardly what we should describe as regal. Parkinson knew and loved this old plant, for it was introduced about 1590. "The Crowne Imperiale,"

Crown Imperials love rich living, and for the best results the bulbs should be lifted every three or four years and given more room. I have them established in full sun under a south wall, flowering regularly and freely, but in light soils it is important to see that they do not dry out when in active growth, and principally for this reason I think half shade or a north aspect is then the best place for them. They are admirable for massing in shrubberies and borders, and though their flowers are hardly suitable for use in room decorations, in a large hall a bold vase of Crown Imperials makes a handsome subject.

F. chitralensis.—In 1910 the Royal Horticultural Society gave an award of merit to a very interesting yellow Fritillary from Chitral, which, in spite of many obvious differences, the botanists insist on describing as a variety of *imperialis*. The bulbs are only about the size of a pigeon's egg, and the whole plant is much more slender than our Crown Imperials. The leaves, too, are scattered instead of whorled, and the flowers come out in February or March, well before those of the type, and without any unpleasant smell. We have not yet had it long enough to say much about its culture, but I have a good stock, and do not think it will prove difficult.

F. pallidiflora.—Having disposed of these two dominant species, it becomes somewhat more difficult to pick the best third. I should vote without hesitation for *pallidiflora*, but it is so seldom seen or praised that one might imagine there was something difficult about it. It has very large, pale creamy yellow bells, in a loose, open inflorescence, one or two bells on poor plants, but seven or eight on good bulbs, and well disposed above broad, distinctive grey foliage. When the flowers are fertilised they often suffuse with a brownish shade in a handsome way, and then the seed-pods erect themselves and become showy too, for they have large, winged ribs. It is a plant with character. I grow it in full sun in heavy soil, but I know others recommend half shade for it, which leads me to think that success very likely depends on the underground water supply. It flowers practically through the whole of April.

F. persica.—I hope I am not doing *persica* an injustice in placing it fourth, for it is a very old favourite, known to Gerard as long ago as 1596, whereas *pallidiflora* is a comparative newcomer, which we owe, I think, to Dr. Regel. When it thrives, *persica* is one of the most distinct and beautiful, and its cheapness is a sign that it does generally thrive. It is one that is quite good on light soils. The flower-stem rises 2 feet to 3 feet, and in the upper portion carries as many as fifty of the plum purple, metallic-looking, fragrant bells in April and May. The foliage, too, forms a handsome groundwork, from which the flower-spire springs; there is no weakening of the effect by running large bracts among the flowers, as in some of the species. R. W. WALLACE

(To be continued)

FRITILLARIA PERSICA, AN EASILY GROWN SPECIES AND A TIME-HONOURED FAVOURITE IN GARDENS.

he says, "for its stately beautifulness deserveth the first place in this our garden of delight, because it is so well knowne to most persons, being in a manner everywhere common." This, too, has many garden varieties. I like best the large yellow (*F. maxima lutea*), but the giant red is not inferior to it, and the kinds with gold-striped and silver-striped leaves are among the most handsome of variegated plants. *F. inodora* is a scentless form from Bokhara with brownish red flowers. This is fairly common, but there is a purple form, also scentless, introduced in 1885, which I very much wish I could get.

DAFFODILS FOR POTS.

THERE must be few people nowadays who have not pots of Daffodils or Narcissi of some kind. Why not try to extend a little this season? No plants are more easy to manage.

By a judicious selection of varieties and by the thoughtful use of a cold frame as a feeder to the glass house a long succession of bloom may be maintained. From early December, when we may have Paper-white Polyanthus Narcissus, onward up to the time of the outdoor flowers coming in, there should be no difficulty in having a few potfuls of bloom. The two best varieties to use, if flowers are wanted

in the first week of the new year, are Henry Irving and obvallaris. The next in order are Golden Spur and princeps. After January 21 the number is largely augmented, but (and the "but" is very important) an early potting is absolutely necessary and as early ripened bulbs as can be procured. It might be well worth while for traders to develop this idea and make a speciality of early ripened Daffodils to be delivered at the same time as Roman Hyacinths in August. I had bulbs from Guernsey, Sweden and other places in my greenhouse last winter. In every case the Guernsey-ripened ones flowered first and the Swedish last, exactly as I anticipated. My particular purpose in these notes, however, is to mention some of the new kinds which have been found particularly suitable for pot culture. I have come to the conclusion that I cannot repeat myself too often in the advice I have to give, for these take more getting known than anybody would imagine. I am very glad to see that firms like Messrs. Barr and Sons, Messrs. Cartwright and Goodwin, Mr. C. Bourne, Messrs. Sutton and Sons, and doubtless others make selections of particularly suitable varieties. It is all in the right direction, but when a hundred kinds are included in a list a considerable part of its utility is lost. It would be better in tabloid form. I want, first of all, to mention three or four out-of-the-way flowers which are never or hardly ever met with in the usual retail lists, but which are, nevertheless, real "front rankers." Stromboli, an elegantly formed yellow trumpet, and Coronet, a most graceful bicolor trumpet, are ideal plants for early pot work. Golden Spider is another good thing. Its time of flowering is after Golden Spur. It may be described as a yellow form of princeps. I can grow it myself at Whitewell, and although my ground is late, I have had excellent blooms from home-grown bulbs quite early, which is a very useful thing. Cervantes, which, I believe, is an Italian form of princeps, is not so much grown as it should be in our greenhouses. It is deeper in colour, and its trumpet has a wider and more frilled top than that of the type, while its segments are somewhat shorter and broader. Beethoven is the last of my special "specials." It figures in the "Daffodil Year Book" for 1914. I have the highest opinion of it for pot work, and its distinct shape and colouring make

it a marked plant wherever it is grown. No other variety that I can think of has such a jagged edge to its trumpet. It is like a huge cross-cut saw compared to the fine-toothed one of the kitchen.

I pass now to the ordinary kinds that figure in nearly every list, but which cannot be too well known or too much used for the purpose for which they are selected. Prices, I fear, will put "top weight" on some, but one well-grown bulb in a 4-inch or 5-inch pot is capable of affording very great pleasure, and if it is well looked after when it has done blooming and then carefully dried off, it may be planted out in the open in the autumn but little the worse for its adventure. One or two florins or half-crowns laid out in this

TULIPA RETROFLEXA. COLOUR, SOFT YELLOW.

way by those who can afford to give themselves a little treat will, when blooming-time comes round, be considered money well spent. King Alfred must head the list, if only because I think trumpets, giant Leedsis and giant incomparabilis are the best of all types for pots, and of the trumpets King Alfred is the undoubted king. Then we have Weardale Perfection and Duke of Bedford, while for earliness and freedom of flowering Fairy is difficult to beat. Blackwell, Firebrand and Lucifer are fine for providing colour, far in advance of any of the old originals like Cynosure and even Beauty. Fairy Queen among the Leedsis is a little gem of the first water. It comes early and easily. Then, of course, Lady Margaret Boscawen as a giant incomparabilis

and Seagull as a pale Barri are both very fine. Lastly, Admiration and either Alsace or Aspasia (according to whether an earlier or a later one is wanted) among the Poetaz make up a select dozen, every one of which is in its way first-rate.

JOSEPH JACOB.

TULIPA RETROFLEXA.

THE curiously recurved flowers of Tulipa retroflexa give to this plant a peculiar charm and make it quite distinct from all other garden Tulips. The origin of T. retroflexa appears a little doubtful, although it is generally believed to be a garden hybrid between the Turkish Tulip, T. acuminata, and T. gesneriana, the latter parent, according to Baker, being the original stock of most of the late-flowering Tulips. Whatever the origin of T. retroflexa may be, it is unquestionably a beautiful subject worthy of extended planting in the open, and of great value for cut flowers and table decoration in the spring. It is quite easily grown, and produces its soft yellow flowers in early May.

DARWIN TULIPS.

FASHION, the "universal" captain on the bridge, has kept the engines of the good ship Darwin going "full speed ahead" for a very long time. Messrs.

Krelage and Son, the makers, thought she might perhaps do eighteen to twenty knots, but she has left that far behind, fairly astonishing them with her speed, and is now doing a comfortable thirty, with every likelihood of her reaching an ultimate forty.

Marvellous have been the strides which the Darwins have made in popular favour within the last two or three years. Those who visited the Royal Horticultural Society's Tulip nomenclature trials at Wisley last spring will have noticed the large extent of ground that they covered. Speaking from memory, I should say there must have been almost as many Darwins as all the others put together. As far as I am able to judge, this is but a true reflection of the popular taste. What has brought them so

much into favour? Undoubtedly, first of all, their extraordinary effectiveness in gardens, both in small clumps and in masses. Half-a-dozen Farncombe Sanders look fine in a border. Two hundred are gorgeous in one solid block in a bed. Secondly, their value for growing under glass is being more appreciated every year. The appearance of Sweet Lavender at one of the January "Tuesdays" of the Royal Horticultural Society was a veritable eye-opener to many. I shall not forget in a hurry my surprise when I opened a parcel post box that reached me on January 6 bearing the postmark of Leiden and the name on the label of de Graaff Brothers, and found therein six beautiful blooms of Sweet Lavender. I have learnt since that these blooms were a sort of first-fruits of a

very extensive trial that they made last winter to test the suitability or otherwise of various Darwin varieties for forcing. I have more than once done the same myself, only I have always been content to try for a first week in March flowering, whereas they tried to bring them in very much earlier. I should imagine, however, that these will be more useful for using as cut flowers than in pots, on account of the length of their stems. Let me deal with their culture under glass first. If the object is to have very early flowers in February, the bulbs should be potted in September and then placed under sand or in a darkened cold frame, as is usually done. On January 1 they should be given a temperature of 50°, and in two or three weeks from then, according to the way they are seen to respond to the slight heat, they should be placed in another house where they will have 70° and where they will flower. If the idea is to have pot plants or flowers for cutting in March, the same early routine must be followed; that is, the bulbs must be rooted and then placed in a cold frame which can be protected from frost, where they must remain, having the whole time as much air as the state of the weather will allow, until the end of January, when they must be removed to a house with a day temperature of 50° to 55°, and which does not fall below 40° at night. Here they will bloom from about March 10 onwards, according to their respective earliness or lateness. Treated in this way I find I always get good strong stems which are very little "drawn," so that the potful is quite usable, as it is in suitable positions on the floor. By placing them low down, two advantages are gained: First, the inevitable tallness is not aggressive; and, secondly, the beautiful bases and interior of the blooms can be enjoyed, which is impossible if the flowers are above our heads. Mr. Jan de Graaff very kindly sent me a copy of the results of his firm's trials. The following are the ten best of the earliest bloomers, every one of them being in flower before February 14: Erguste, Fanny, L'Ingénue, La Tristesse, Pride of Haarlem, Rev. H. Ewbank, Sierrad van Flora, Sweet Lavender (late William Copeland), William Pitt and Zanzibar. Those which I have found good for March flowering include Zulu, Painted Lady, Suzon, Professor Rauwenhoff, Erguste, Pride of Haarlem, King Harold, William Pitt, Edmée, The Bishop, Loveliness and Ouida.

Passing now to the question of outside planting, there is not a great deal to be said. I would never plant before November. The old-fashioned day for the operation, although it originally concerned only the striped florists' varieties, is equally suitable for our modern Darwin and Cottage forms. Lord Mayor's Day should be mentally noted as the ideal time for Tulip planting. The only ones that need be put in earlier are the small offsets, which should

never be out of the ground after the end of September.

I have read somewhere that the original stock of Darwins bought by the present Mr. E. H. Krelage's father contained upwards of two thousand kinds. I can well believe it, for the number that is catalogued at the present time is prodigious. I have before me as I write the third list of Darwin Tulips issued by the introducers in 1891. It contains 300 varieties, which vary in price from five pounds for La Tulipe Noire to sixpence for some that are now quite unknown, with the exception of Pomona. The same firm's list for 1914 contains 152, the most expensive of which are Orange Perfection and Aphrodite, 5s. each; and the cheapest, Fanny, Fra Angelico, Gudon, La Candeur, Millet, Paris, Pomona, Pride of Haarlem, The Sultan and van Poortvliet, to name but a

dear, being, in fact, my pick of a "real good" twelve.

The cheap list: Dream, Margaret, Fra Angelico, Loveliness, Pride of Haarlem, General Köhler, Clara Butt, Baronne de la Tonnaye, Millet, Nauticus, La Candeur and Edouard André. A real good dozen: Euterpe, Pride of Haarlem, The Bishop, Morales, City of Haarlem, Valentin, Bleu Aimable, Clara Butt, Louise de la Vallière, Scarlet Perfection, L'Ingénue and Sir Trevor Lawrence. I have written down the above, the choosing of which must have added more grey hairs to my already plentiful stock, but I do not like leaving out Erguste, Mr. Farncombe Sanders, Frans Hals, Suzon, Petrus Hondius, William Goldring, La Fiancée, Faust, Anton Mauve, Prince of the Netherlands, Zulu and Millet, and so I could go on for ever until almost

DARWIN TULIPS IN A FORMAL GARDEN.

selection, all priced at one penny. It is truly a staggering list to confront the would-be purchaser of a humble dozen; no wonder he falls back defeated. Whatever is he to do? I appreciate his dilemma. My experience of them is fairly wide, and when I come to pick out the best dozen I am utterly nonplussed. It cannot be done. Mr. Jan Roes, the Tulip O'Brian of Holland, the chairman of the Dutch Bulb Growers' Tulip committee, could not do it. Mr. Walter Ware, who has handled almost every variety "that ever was," could not do it. It would be a bigger task than putting together without a key one of those thousand-piece puzzles which were so much the rage two or three years ago. After saying so much I am not going to attempt it. Instead I am going to give two selections containing twelve varieties each, both of which will be representative and varied in colour, one being confined to the cheapest kinds and the other including both cheap and

the whole of the afore-mentioned two thousand were included, and I would end by making confusion doubly confounded.

TROJAN.

PLANTING BULBS IN GRASS.

WHILE it is generally agreed that bulbs look extremely beautiful when flowering in the grass, at the same time the bulbs require to be planted with a little forethought. A very common error is to mix varieties at the time of planting, and as the flowering seasons of different varieties seldom coincide, the general effect in springtime is much impaired. This is particularly the case with purple, white, and yellow Crocuses, which give far better results when the colours are kept to themselves. The illustrations of white Crocuses on grassy mounds and Narcissus Barrii conspicuous naturalised in the grass (pages 455 and 458) give one an excellent idea of the bold effect to strive for when planting bulbs in grass.

BULB NOTES, 1914.

AMONG those who must owe a debt of gratitude to the British Navy at the present time may safely be included the members of the Dutch Bulb Growers' Association. Thanks to it the German ships of war have been so tightly bottled up in the Kiel Canal and the Baltic that the greater part, if not the whole, of the usual shipments from Holland are being sent across the North Sea, and by the time these words are in print they will have been landed on our shores. This means, above everything else, Hyacinths. Ever since the days of George Voorhelm, in the middle of the eighteenth century, the Hyacinth has been the flower of Holland. Something in the soil or its treatment, or both, enables the Dutch to produce the very best of bulbs, and except for a comparatively few home-grown ones, they supply the world. Doubles and singles have fought for precedence in the past; now a new type has come to the front. It is the day of the

Miniature Hyacinths. My ideal flower of the group is Orange Boven. It is distinguished by its loose spike and its small, neat bells. It has a good deal of the look of a Roman Hyacinth. In colour it is a pink buff. No other kind quite comes up to it in charm and grace, but the following come near it: Solfaterre (orange crimson), Grand Maître (medium blue of a very pretty shade), William III. (dark blue), General de Wet (pale pink), Winter Cheer (red) and Queen Wilhelmina (rosy pink, with curious little hooks at the ends of the petals). These should be always planted in small pans or low pots. I know I am always saying this about certain plants. If I seem to repeat myself too often, it is because I feel sure that if people only realised how much is gained in the *tout ensemble* of plants and pot, they would be universally used.

Ordinary Hyacinths.—One or two varieties struck me very much this year: Garibaldi (an early rich crimson), Queen Maria Sophia (early crimson with pink edge), Count Andrassy (wide blue petals with edges of mauve and very blue backs, loose spike, a clear-looking flower), Tortula (a lovely blue, Schotel improved), Ornament Rose (waxy-looking pale pink bells) and Perle Brilliant (short, fat spike, bells a fascinating shade of pale bluish mauve with very blue backs).

Early Tulips.—White Beauty, a sport from the well-known Pink Beauty, is singularly well named. The white is quite pure and the habit of the plant so good. De Wet, a sport from Prince of Austria, is an orange with a network of tiny red veins running all over the petals. With

age these become a good deal more pronounced. Distinction is two shades of crimson, the edges of the petals being brighter than the middle part: President Cleveland, long white flower with wide, pale rose edges to the petals; Max Havelaar, a paler and more orange Prince of Austria.

Tulip Species.—In this rock garden era I am sure the little branching *Tulipa dasystemon* is not sufficiently known. It has a small white flower with a large yellow base. It wants a sunny position, as it is one of those which only open wide in sunlight. Given a light soil, it will be found to increase and produce a large number of seeds.

BRITISH WOOD HYACINTHS (*SCILLA NUTANS*) IN A COPPICE.

Coloured Freesias.—Whenever the yellow and pinkish kinds have been staged I have frequently asked attendants about their popularity compared with the old pure white forms, and the invariable answer has been "The public do not appreciate them." One reason, perhaps, is that the colours are not clear and that the blooms have such a half-opened appearance in many of the varieties. These defects will doubtless be remedied in time. Meanwhile, of those which have come under my notice the prettiest are Contrast, which is the fac-simile of an orange tip butterfly in Freesias; Le Phare, well named, small individual flowers, but brilliant in a mass; Abundance, many flowered, blooms of a good open shape,

pink in their youth, deep rose in old age. Suttons have a good deep yellow, for they most kindly gave me some two or three years ago, but which it is I cannot make out from their list, as they only refer to colour in their descriptions, and colour is no more important than style when appraising the merits of a Freesia. I missed a variety called Excelsior, which obtained an award of merit on February 24 of the present year. Size and earliness are its notable points from the accounts in the papers. There is very little doubt that in a few years' time these easily managed bulbs will occupy a more important place among the early spring bulbs of our greenhouses than they do to-day.

Scilla campanulata.—These are the wild Wood Hyacinths of Spain, and must not be confounded with the early little deep blue flowers that are generally spoken of as Scillas. They are very similar to British Wood Hyacinths (*Scilla nutans*), but have larger bells, which are arranged symmetrically all round the spike, and not so much like a pastoral staff or shepherd's crook as in our own. They come into flower about the end of May, and might be introduced into beds and borders much more often than they are. Of course, they do splendidly in coppices or thin woods, and slowly brought on in pots they come in nicely as a change from Daffodils and Tulips in early April. Their garden nomenclature seems a trifle uncertain. There is a good pure white, usually called alba or alba maxima; another, Excelsior, a good deep blue; and a third, Rose Queen, a pretty mauve pink or pale rose. Blue Queen is a paler shade of blue, and Rosalind a deeper rose.

Scilla italica.—This flowers a long time after all the Scillas. I think it was July before it flowered with me this year. It resembles *Hyacinthus amethystinus* in its general bearing, and I have no doubt it would make an interesting plant for the rockery. The typical flower is a pale blue, but there is also a white variety. This *Scilla* and also *H. amethystinus* are so cheap

that they might both be given a trial for half-a-crown.

Crocus Species.—Everyone who has a warm, sunny, sheltered corner or two in their gardens should go in for a hundred or two of these heralds of spring. The day which tempts the honey bees from their hives is also the one when these are usually seen at their best. Wide open, full of buzzing, foretastes of warmer days, who would willingly be without some of these pretty, simple little blooms to give patches of colour, life and joy in the chilly time betwixt and between the rigours of winter and the balmy days of spring! *C. Imperati*, *C. Sieberi*, *C. tommasinianus* and *C. biflorus* are their names.

TRAVELLER.

COLOURED PLATE.

PLATE 1501.

THREE GOOD DAFFODILS.

I DID not select the title for the coloured plate. The Editor did. He is probably a prophet, so it is all right, but Olympia and Florence Pearson are one thing and Agatha is another. Let me illustrate my meaning by a simile suitable to the times. Roberts and Kitchener are one thing, Jellicoe is another. You have the tried and the comparatively untried placed together, that is all. The untried may be every bit as good as the tried, but the spurs have to be won. If anything will ever knock out Emperor, Olympia will be the flower to do it. If anything within any reasonable time will do the same to "Madame," Florence Pearson will be the culprit. Can I say more? I cannot say less, because that is my candid "foolish opinion," as my old gardener used so often to say to me. Agatha I remember very well. It was one of the adornments of my good friend Christopher Bourne's semi-circles when he had a corner position at the end of the hall (Royal Horticultural Society's Hall) one Tuesday last April. It is an exceedingly pretty flower, and from such an inspection as can be given in the hurry and bustle of a show, it substantiated all that is claimed for it, "pure creamy white throughout, perianth segments slightly pointed and twisted like King Alfred, . . . beautifully proportioned trumpet, frilled and recurved at the brim. The flower opens a week before Mme. de Graaff, and opens white. Tall stem; vigorous plant. Indispensable to exhibitors who want a good white trumpet at a moderate price." Six shillings each, three bulbs for fifteen shillings. It is the very thing I want, Mr. Editor. Thank you so much for reminding me about it. I must try to secure fifteen "hobs" worth.

CROCUS VERSICOLOR.

ONE of the prettiest of the spring-flowering Croci is *C. versicolor*, hailing from Southern France and Italy. With me it comes into flower during February. The flowers (see illustration on page 457) are large and peculiarly cup-shaped, and do not reflex like so many other species when the sun strikes them. In the interior of the flora' cups gleam the golden orange stigma and yellow stamens, forming a striking contrast to the shimmering, satin-like texture of the petals, which are white in colour, veined and feathered with rich violet purple. I plant outdoors in September fairly deeply, say, 4 inches to 5 inches, as the bulbs appear to thrive just as well, and by this means are protected to a considerable extent from damage when planting other subjects in their neighbourhood. REGINALD A. MALBY.

THE CULTIVATION OF LACHENALIAS.

IN the Lachenalia we have an ideal plant which may be grown either in pots or baskets for home or conservatory decoration. While other bulbous plants, such as the Hyacinth, Narcissus, Tulip and Freesia, require a warm, genial atmosphere to bring them to perfection, the Lachenalia is not so fastidious, and its cultivation quite simple by comparison, with the additional merit that instead of deteriorating each year, the bulbs improve in quality. There are several varieties, all of them beautiful, in colours ranging from green and yellow tipped with red to deep yellow.

(Necessary for when in full growth much water is required), and after this has been attended to, three parts fill the pot with the compost, making it fairly firm; then place five or six bulbs around the pot and fill to within half an inch of the rim of the pot with soil. The pots should then be placed in a frame and well watered, after which the lights may be drawn on and covered with light material to prevent the pots from becoming dry so quickly as to necessitate frequent watering. If this is done, only an occasional watering will be necessary until growth has begun, after which they should never be allowed to become very dry. In this position the plants may remain growing steadily, though slowly, until October, when they are ready for putting on a greenhouse shelf near to the glass. I put mine within 6 inches

CROCUSES NATURALISED ON GRASSY MOUNDS.

Of the latter shades I consider *L. Nelsonii* to be the best, when the true variety is grown; but, unfortunately, there are spurious stocks in commerce. My first acquaintance with this variety was at Belvoir Castle, in the late William Ingram's time, by whom it was very highly prized. With me it was "love at first sight," and I then determined that as soon as I was in a position to grow them personally, they should be my constant friends—this variety in particular.

Experience has taught me that August is the best month for starting the bulbs, and the soil should be prepared a week or so before it is wanted. This ought to consist of fairly light loam three parts, decayed leaf-mould or old Mushroom-bed manure one part, with a sprinkling of small charcoal and silver sand to keep the compost open. The most suitable pot is a 4½-inch or 5-inch, for if larger sizes are used they look disproportionate to the size of the plant. Good drainage is

or so, and this keeps them very sturdy and healthy, and there they remain in a temperature rarely above 50°, and often below 40°, until they are coming into flower. In frosty weather the thermometer may even go down to freezing point and not harm them, and it is certainly better to err on this side than to give a lot of heat.

When the flowers begin to expand, it is better to place the pots on a stage further from the glass, as this treatment will help them to last longer, for the sun's rays are very warm by February and March. Although some recommend liquid manure-water, I have not used it at any time during the last few years, apparently to their advantage. Plenty of water must be given during the flowering period and until the foliage begins to turn yellow, when only occasional waterings will be necessary for the next two weeks. The pots must now be put on a shelf in the full sunshine, and thus allow the

bulbs to be completely "baked." Thorough ripening of the bulbs is one of the secrets of successful culture, and they may be left in that position until August, when they should be shaken out of the soil and graded into two sizes—the large, old bulbs to be repotted as previously advised, and the younger and smaller bulbs may be placed twice as thickly in the pots as the larger ones and be given the same treatment throughout. Every one of these small bulbs will flower, but, of course, the spikes will be smaller.

West Moors, Dorset.

F. LANSDELL.

HIPPEASTRUMS AND THEIR CULTIVATION.

AMONG the various classes of plants that have been greatly improved within recent years

richer colour, and with the green in the centre nearly eliminated. In speaking of this species in the past tense, one is justified by the doubt whether the typical species is still in cultivation.

Apart from the superior form and size, a noted feature of the present-day race of Hippeastrums is the increased number of flowers that are borne on a scape, but more particularly the wide range of colour that is to be found among them. The white variety is now an accomplished fact, and there are also pinks of various shades, carmine, ruby, scarlet, crimson, and almost purple, as well as salmon and different allied hues. Besides these, striped and flaked flowers are very numerous, but according to present-day ideas these are less popular than they were at one time.

Propagation.—Hippeastrums can be increased to a greater or lesser amount by means of offsets; but the general mode of propagation is by seeds, which in a general way ripen freely. As with

plants, it is, in my opinion at least, much better to sow them when they are ripe. It matters little whether the seeds are sown in pans or pots, but in this last case a liberal amount of drainage is necessary. A compost made up of equal parts of loam and leaf-mould, with a liberal sprinkling of silver sand, is very suitable in which to sow the seeds. Care must be taken not to sow them too thickly, and they should be covered with about one-third of an inch of finely sifted soil. Then, if placed in a structure where a temperature of 65° to 70° is maintained, they will soon germinate and the young plants grow away freely.

Treatment of Seedlings.—When sufficiently advanced, they may be potted singly into small pots in the same kind of compost as that in which the seeds were sown. They should be ready for this potting off by October, when, if a gentle bottom-heat is available, they may be plunged therein, the top temperature during the winter being a minimum one of 60° to 65°, rising, of course, during the daytime. A good light position in a small structure suits these Hippeastrums best. By the end of February they will be ready to shift into 4-inch pots, and by the latter part of May another change may be desirable. Pots 5 inches in diameter are very suitable for this. At the end of this season they will not need to be dried off as established plants are, but, at the same time, less water will be needed than when they are growing freely. In this way an occasional seedling will flower in eighteen months or a little more from the sowing of the seeds, but the character of the flower cannot be decided upon till a year later.

Repotting Established Plants.

At one time it was considered necessary to repot Hippeastrums every year, but this is now seldom done. Some prefer to divide the collection into two batches—thus each plant is repotted in alternate years; while others allow them to go longer than that. In any case, those that have not been repotted must be well fed during the growing season. Repotting is generally, though not universally, carried out early in the year, just as the plants are about to start

into growth. At that time a temperature of 60° to 70°, increasing as the season advances, will be very suitable for them. After the flowers are over is a very important period with the Hippeastrums, as they need to be kept in a growing temperature in order to ensure well-developed bulbs. If the pots are well furnished with roots, liquid manure will be helpful. When growth is completed, the plants may be removed to a sunny frame, husbanding the sun-heat by shutting up the lights early. With this treatment the bulbs will become firm and gradually ripen under the influence of the summer sun. As the leaves turn yellow, less water will be needed, until, when the bulbs are totally dormant, it may be discontinued altogether. During the winter, when dry, the temperature of the structure in which they are kept must not fall below 50° to 55°. H. P.

THE WILD WOOD HYACINTH OF SPAIN (SCILLA CAMPANULATA).

must be included the Hippeastrums, which are, however, far more generally grown under the name of Amaryllis. The garden forms of the present day have resulted from the crossing and intercrossing of several distinct species, but some have played a much larger part than others. For instance, *H. aulicum*, though the flowers are large and showy and the plant of easy culture, has the segments much too pointed to commend it to the hybridist, who is aiming at the production of round, well-filled-in flowers.

A species that has played a very prominent part in the varieties of to-day is *H. Leopoldii*, which, discovered by Richard Pearce of tuberous Begonia fame, first flowered in the early seventies. The flowers of this were crimson, with a large green centre; but continued selection has resulted in a much superior flower, larger, rounder, of a

all other classes of plants, some individuals are better adapted for seed-bearing than others. In crossing flowers for the production of seeds, the greatest measure of success is attained when it is limited to members of the same section, as then the production of improved forms is quite within the bounds of possibility; whereas when widely diverse forms are crossed with each other, a mixed and not very desirable progeny is usually the result, though occasionally distinct shades of colour crop up in this way.

Seed-Sowing.—From flowers that are fertilised in the spring, the seeds may be expected to ripen in July, or very soon afterwards. This is shown by the pods splitting open and exposing the black winged seeds. Some cultivators prefer to keep the seeds until the spring; but, given a suitable structure for the accommodation of the young

BULBS IN THE ROCK GARDEN.

IN choosing bulbs for the rock garden it is important to avoid any species or varieties which would appear incongruous among rocks and alpine plants. No law can be laid down on this point. It is purely a matter of taste. But to illustrate what I mean: The natural species of *Crocus* all look well in the rock garden, while the rotund Dutch varieties, which sparrows love to kick to pieces in the borders, are better away from alpine plants. Also, not only should one preserve a sense of proportion or scale between the size of one's bulbous plants and the size of one's rock garden, but care must be taken in putting the right bulbs under the right rock plants. Such things as Daffodils and Bluebells, though quite in place in the coarser outskirts of a large rock garden, become giants on a small one. The thoughtless planting of a lusty *Narcissus* under some choice tufted silver *Saxifrage* would probably mean that the latter would be butted clean out of the ground in spring.

Of *Crocuses* there are many beautiful species for the rock garden. *C. speciosus* is one of the easiest to grow. It flowers in September, a splendid butcher blue. Among the best spring-flowering kinds are *C. Imperati*, inner segments pale lilac, the outer ones buff, with deep purple featherings; *C. susianus*, golden orange, feathered with chocolate; and *C. tomasinianus*, lilac.

Among the many species of *Tulipa*, three very satisfactory ones for the rock garden are *T. persica*, *T. clusiana* and *T. kaufmanniana*. *T. persica* is a quaint dwarf, with usually two yellow flowers hanging from a 4-inch to 5-inch stem. It may be planted among such dwarf things as the smaller *Campanulas*. *T. kaufmanniana* is also short in the stem, and should be planted accordingly; but its flowers are large, like great Water Lilies, and palest yellow, each segment with a stripe of soft pink. A group of these, fully expanded in the sun, is a glorious sight. *T. clusiana* is tall and graceful, the flowers white, very long and pointed, and each segment with a stripe of pink.

Of the *Irises* there are many bulbous species, and some of the dwarfer ones are excellent for the rock garden. *I. reticulata*, 5 inches to 6 inches high in earliest spring, bears flowers of rich violet colour and rich violet scent. Its variety *Krelagei* bears flowers of claret violet. *I. Histrio* and *I. histrioides*, of a more lavender blue, have brilliant and very early flowers, and both are a little uncertain unless the soil happens to suit them. The same may be said of *I. Danfordiae*, which is dwarfer than any, and has sturdy, broad flowers of bright,

clear yellow. The curious *Snake's-head*, *I. tuberosa*, a foot high, with flowers of chocolate and apple green, is worth naturalising in rather light soil in full sun on any fair-sized rock garden.

The finest *Colchicum* is the autumn-flowering *C. speciosum*, with immense blossoms of lilac pink in September. This is not a plant for a small rock garden, especially on account of its coarse summer foliage. There is a superb snow white variety of this species. Among *Snowdrops*, *Leucojum Elwesii* is, perhaps, the finest, but I like the common old *L. nivalis* and its double form the best. The smallest rock garden should have a clump or two of *Snowdrops*, and clumps

rosy flowers in September. There is a rarer, pure white variety of this. Both are easy to establish, and where happy and undisturbed, self-sown seedlings will appear. *C. europæum* flowers also in late summer, and its dainty pink blossoms are deliciously fragrant. For early spring flowering there are *Cyclamen Coum* and *C. Coum album*, pink and white; *C. ibericum*, deeper red; and *C. repandum*, pink, with long, slightly twisted petals.

The miniature *Narcissi* are so very dainty and charming that they may be planted in the smallest rock garden and among the choicest alpine. The best are the varieties of *Bulbocodium*, *N. cyclamineus*, *N. minimus*, like a minute *Lent*

Lily, 1 inch or 2 inches high; *N. moschatus* and *N. triandrus albus*. It would be interesting to experiment with some of these in the moraine. Of larger *Narcissi*, my favourite for the bolder parts of a large rock garden is *N. Johnstonii* Queen of Spain. Personally, I dislike the highly bred modern race of *Narcissi* in the rock garden. They are beautiful in themselves, as hybrids so often are, but the rock garden does not seem the place for them.

The *Snake's-heads* or *Fritillaries*, *Fritillaria Meleagris*, are almost too well known to need special description. On any but quite small rock gardens they are well worth planting. They may be planted in scattered drifts, either mixed, white and pinkish, or separately. There are a good many other attractive species of *Fritillaria*, of which the following should be tried: *F. aurea*, rich golden bells mottled with brown inside, height 6 inches; *F. citrina*, a curious green and citron yellow flower, a trifle taller than *aurea*; and *F. recurva*, one of the most beautiful and brilliant, with flowers of rich orange scarlet, the petals recurved like a *Turk's-cap Lily*.

Some time ago I tried *Anomatheca cruenta* on the rock garden. It did very well, seeded itself about and stood the winter without

protection. It is a brilliant and dainty thing, rather in the way of a tiny *Freesia*, 4 inches or 5 inches high, the flowers smaller than those of a *Freesia*, and more starry open, bright cherry red, with a crimson red bar across each petal. But to me it is not quite the plant for the rock garden. It is a Cape bulb, and for some indefinable reason it looks out of place among alpine plants. But it is such a jolly little thing and so little known generally that I could not resist mentioning it in place of a hundred good bulbs that I have left unnamed, and which really are quite suitable for planting on the rock garden.

Stevenage.

CLARENCE ELLIOTT

CROCUS VERSICOLOR IN A ROCK GARDEN NEAR LONDON.
(See page 455.)

they should be, not scattered drifts. They look prettiest, perhaps, in angles and nooks between rocks at the path-sides, springing through low, close carpets of green.

About *Anemones* I hardly dare begin; there are so many of them, and all are so beautiful. A *fulgens* one must have for its dazzling scarlet, black-eyed flowers; also *A. nemorosa robinsoniana*, the pale lavender Wood Anemone. *A. blanda* is not unlike it, and varies from white, through lilacs and lavenders, to the superb deep violet variety *Ingramii*.

The tiny hardy *Cyclamen* should be grown in shady corners. *Cyclamen neapolitanum* has handsomely marbled, Ivy-shaped leaves and charming

NOTES ON AURICULAS.

IN September, work among Auriculas consists chiefly in giving all the air possible, careful watering, and keeping the plants clean. The lights can still be removed, except in wet weather, the object being to make the plants hard—to use a gardening term—and to secure that sturdy growth which Auricula-growers delight to see at this period of the year. If the plants are weak and drawn, it will be a difficult matter to bring them safely through the damp weather which we usually experience about December. I trust readers will pardon me for again referring to watering, but it is important that water should only be given when necessary. The plants ought to be looked over every second day for this purpose, and water must not be allowed to accumulate in the hearts of the plants, this remark applying

an excellent account of themselves in the open ground.

Seedlings.—All the seed required was sown as soon as it was ripe, and that sown early in July has already germinated and formed two tiny leaves. When large enough they will be pricked off, about an inch apart, in pans or boxes of rather light soil. Here they will remain for the winter months, arranged a foot or so from the glass of a cold frame. All decayed leaves should be picked off, and the soil may be stirred with a pointed stick occasionally to prevent it becoming sour and green. A sweet and open compost is very essential in Auricula culture. Some of the seeds will probably lie dormant until the spring, so it is not advisable to dispense with the seed-pans for some months.

Keep the Plants Clean.—Cleanliness is most important, and green fly must be destroyed by fumigation directly it is seen. I always try at

ROSE-GROWING IN TOWN GARDENS.

IN THE GARDEN for August 8 I am taken gently to task by "White Lady" for an opinion previously expressed in regard to the relative merits of fragrance and shape in Roses. The subject is of necessity one that admits of argument, since it is entirely a question of individual appreciation. My wish was not to depreciate the value of scent, which appeals to me strongly, but rather to refute the allegations of those whose cry is always that this desirable attribute is becoming lost, which is far from being the case. The connection between smell and memory is a fortuitous one, varying in extent and effect in each individual, and one may doubt whether the exercise of other senses do not give equal pleasure in their relation to memory. From an artistic or æsthetic point of view one must place shape first. To me it brings the greater pleasure, but I have no quarrel with those who think otherwise so long as their Roses are a source of joy to them.

Those who have not yet cut away the old growths of Wichuraiana and Multiflora Roses should lose no time in completing this task. The new growths can now be tied out so that each is obtaining as much air and sunshine as possible. Ramblers that are at all prone to mildew ought to be carefully looked over, as the crowded growths of late summer will have rendered them more liable to become affected. In addition to spraying, where it is possible the tips should be bent over and dipped in a pail of the wash. If the fungus is now allowed to spread, it will attack the soft stems, and the plants will lose much of their vigour, besides assisting to ripen innumerable quantities of mildew spores in their hard winter cases, which are practically indestructible. A careful look-out ought to be kept for black spot, and if it appears, one should be prepared to take the most drastic measures to combat it. In a small and often crowded town garden one cannot afford to risk the spread of this

disease, and I would advocate the immediate removal and burning of the plants affected; but if this is not desired, every leaf which shows signs of the disease should be picked off and burned, and the trees all round sprayed thoroughly with a reliable fungicide at the full strength recommended. Subsequently the same treatment may be given at least once a week, picking off all diseased leaves as frequently as possible in the meantime. On no account must these be allowed to lie in a rubbish heap, even in a remote corner of the garden. Burning is the only way to make sure that the spores will not spread, and the sooner this is done the less will be the risk.

All cut parts of the stems of Roses, especially standard trees, ought to be carefully looked at, and where the pith has been bored, the sawfly grub should be extracted before it has gone deep enough to damage the plant irretrievably.

P. L. GODDARD.

NARCISSUS BARRII CONSPICUUS NATURALISED IN GRASS.

more especially to the show varieties. Every attention should be given to these few simple details, and it will then be found that the Auricula is not so exacting in regard to treatment as some would have us believe. It is an amateur's plant, and should be grown by all, either in a cold frame or in the flower garden. I would strongly advise readers to try a few in the open border or rock garden.

In the Open Ground.—Some varieties are very prolific in regard to offsets, especially such kinds as Argus, Duke of York and Thetis, which are worthy of being grown in quantity. A good plan is to plant them in batches in the flower garden or any position where a neighbouring tree will supply a little shade during the hot part of the day. Some of the yellow forms are excellent for this purpose, particularly the beautiful A. Queen Alexandra. From this Auricula, crossed with another named Victoria, I once raised some very good seedlings which gave

this season to examine each plant, and remove all weeds, dead leaves and mossy substances from the surface of the soil. All dirty pots can be scrubbed, so that when the plants are arranged in the frames they will present a smart and clean appearance.

T. W. BRISCOE.

IRIS PALLIDA VARIEGATA.

THE variegated-leaved variety of *Iris pallida* is a handsome plant, either in or out of flower. The variegation of the leaves is quite good and effective, and the plant, as a whole, is much superior to the other variegated-leaved Irises, such as *I. Pseudacorus variegata* or *I. foetidissima variegata*. Apart from the variegation of the leaves, which is finer than that of its two rivals, *I. pallida variegata* has better flowers, which are of a good lavender blue. The variegated form is quite hardy.

S. A.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Cucumber Plants which are intended to produce a daily supply in the winter should be given every encouragement to fill the trellis with short-jointed shoots before they are allowed to carry a crop. Remove rough, overgrown leaves and pinch the young growths at the second joint, so that they may never become crowded or entangled with each other. The longer the plants can be allowed to remain without fruiting, the better will be the result in the winter. Top-dress the bed frequently, so that the roots may be kept active. A night temperature of 70° can be kept up by slight fire-heat, the ventilators being left slightly open to ensure a sweet, healthy atmosphere. The latest sowing may take place now with a view to producing plants for fruiting in the beginning of next year.

Pot Fruit Trees.—There should be no delay in potting the main batch of early forced trees. The soil may consist of three parts turfy loam and the remainder of decayed horse-manure and old lime rubble, with a good sprinkling of crushed bones. Select the earliest varieties first, and give each tree a good soaking of clear water so that the soil may be removed with as little injury to the roots as possible. Pot carefully and work the soil in among the roots with a thin potting-stick. When the new soil has been made firm, the trees should be placed in a shady position and syringed daily while the weather is dry.

Strawberry Plants for Forcing.—The early plants should now be well established, and will benefit by frequent waterings of liquid manure in a diluted state. Keep the runners cut away, and give plenty of space between the pots to admit air and sunshine. The plants will benefit by light dustings of soot in showery weather.

Alpine Strawberries in Pots.—These plants should be grown in a well-ventilated structure. Give careful attention to watering and syringing. Gather the fruits before they are overripe, or the flavour will be inferior.

Plants Under Glass.

Primulas.—The earliest batch of plants should now be ready for removal from the cold pits to a well-ventilated greenhouse where protection from strong sun can be provided. Later plants for spring flowering may be allowed to remain in the cold pit for some time longer, but must be removed to safe quarters before sharp frost sets in.

Hyacinths.—Where pot Hyacinths are in demand, the bulbs ought to be procured and the first batch potted without delay. A good rich soil with plenty of sand should be employed, and when the bulbs are potted, the pots may be covered in a bed of sifted ashes until the pots are well filled with roots. Various bulbs should be potted now and plunged in ashes, so that good roots may be produced before the pots are introduced to heat.

Tulips.—These can now be potted in quantity and plunged in sifted ashes. When a good number of roots have been produced, some part of them may be placed in very gentle heat, as the Tulip, like most bulbous plants, does not respond readily to hard forcing; in fact, this is the cause of many failures. A good number of bulbs should be placed in each pot, so that a good blaze of colour may be produced.

Polyanthus Narcissi.—These should be potted now and plunged in ashes until the pots are well filled with roots, after which they may be removed to a mild forcing-pit as required. If only required for cut bloom, the most economical way is to place the bulbs quite close together in boxes of good rich soil.

The Flower Garden.

Hardy Annuals.—If an early display of these is required, the best way is to sow the seeds in September. The soil should be dug deeply, but ought not to be too rich, or the seedlings may become too soft to stand the winter. Many varieties should be sown in boxes and transplanted as soon as large enough. Antirrhinums, for

instance, may be sown at once and pricked into boxes as soon as large enough. Slight protection should be provided during sharp frost, or many may be lost.

Pentstemons.—Cuttings should now be taken from plants which it is desired to increase. If these are inserted in sandy soil now and shaded from sun, they are almost certain to produce sufficient roots to carry them through the winter, when they may be potted up and planted out early in April. These plants should produce abundance of bloom in June.

The Kitchen Garden.

Spring Cabbage.—The first plantation of Cabbage for spring cutting should take place as soon as possible. Ground recently occupied by Onions will suit the purpose well, and should only be broken up to the depth of a few inches. Plant in rows 18 inches apart and about fifteen inches between the plants in the row. As soon as the plants have started into growth, the surface ought to be broken up with a hoe. This will favour the development of the plants and destroy numerous small weeds. Harbinger, Early Offenham and Milecross Marrow are good varieties for present planting.

Mushrooms.—Beds may be made up now for the supply of Mushrooms in November, and as the days are becoming cooler, there need be no difficulty in obtaining a good supply of them. If horse-manure is available, it should be collected daily and placed in a well-ventilated shed, where it can be turned daily for about ten days, as a great deal depends on the proper preparation of the material. When thoroughly prepared, the manure should be removed to the Mushroom-house and beaten tightly together in a bed 14 inches deep. The spawn may be placed under the surface when the temperature of the bed has dropped to 80°. The atmosphere of the house can be kept moist by frequently syringing the walls and floor, but frequent damping of the bed should be avoided.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Kidney Beans.—Early frost will at once put a stop to the production of pods, in which case it will be wise to go over the crop now and gather all the pods that are still fit for cooking. These may be pickled in stone jars, when, with ordinary care, they will keep their colour and retain their crispness for a long time. Place the Beans in layers in the jar, and between the layers sprinkle some freezing salt; then fasten securely and store them in a cool cellar. It is most important that too much salt is not used, otherwise they will lose the colour and give a bitterness to the taste.

Climbing French Beans.—Where space will allow, a sowing should be made in a small pit where the plants could be trained to the wires. A house previously occupied by Tomatoes would suit them admirably, provided fire-heat could be given when required. Sow in small pots and plant out later. No attempt should be made to force them, and only use sufficient fire-heat to maintain a growing temperature. The greatest possible care must be exercised in watering at the earlier stages of growth, as, if over-watered, the leaves turn yellow, which most certainly ruins the crop.

Cauliflower.—At this season there is usually a glut of Cauliflower, which sometimes is difficult to dispose of, so that to prolong the season of consumption it will be well to draw the plants with as much soil attached to the roots as possible. Hang these head downwards in a cool, darkened shed, and spray them over each evening. In ordinary cases they will keep fresh for quite a long time.

Parsley.—Where Parsley has become coarse and shows a tendency to bolt, it should be cut over. If the weather continues fine, a good crop of young growths will appear. Older plants that are running to seed had better be got rid of, as these very seldom break away again.

Endive.—A frame or cold pit should now be prepared for this fine winter salad, and as moisture

is its greatest enemy, it is advisable to put about nine inches of ashes in the bottom before adding the soil. In planting, allow at least a foot between the plants, and admit air freely on all favourable occasions. As soon as the plants are of sufficient size, the foliage should be tied up for blanching; this must be done when they are perfectly dry.

The Flower Garden.

Tunica Saxifraga.—This pretty little rock plant, with its delicate lilac flowers, has been especially fine this season, and, strange as it may seem, if planted with full exposure to the sun the colour seems intensified. It appears to be perfectly hardy, and germinates freely from seed. As soon as the seed is perfectly ripe it should be sown in a box or pan and placed in the alpine frame.

The Herbaceous Border.—Now that the last of the occupants of the herbaceous border will be in bloom, stock must be taken of the plants requiring to be divided or moved. In a border of any description this annual overhaul is a necessity. Among plants that quickly exhaust the soil, mention may be made of the Monardas. If left more than two years without being divided, the flowers of these become small and weak in consequence. It may be well to remember that in dividing plants, only the strongest shoots from the outside of the group should be selected. There is, of course, great diversity of opinion as to autumn or spring planting, which can only be decided by local conditions. The object here is simply to note intending changes. Carefully note and label each plant to be treated, and on no account disturb the plants until growth is completed.

Carnations.—The earliest layered plants should now be rooted, and, if the ground has been prepared as previously advised, planting may commence any time after this date. If, for various reasons, this has not been done, care must be taken not to use fresh manure. This would encourage soft growth, which would undoubtedly suffer during severe weather. Where planting is deferred until spring, rooted layers should be potted and placed in frames, but the lights must be kept off unless in excessively wet weather.

Dog's-Tooth Violets.—As an edging to beds of spring-flowering plants or planted in groups in the rockery, there are, perhaps, no better subjects for this purpose than these neat little plants with their attractive foliage and equally attractive flowers. To get them established, the bulbs should be planted in a mixture of peat and loam, and no time should be lost in putting in the bulbs.

Plants Under Glass.

Cinerarias.—Although it is not advisable to house these plants for some time yet, they should be carefully examined for mildew, which usually makes its appearance at this season of the year, often the result of insufficient ventilation. Where this is observed, give the plants more room, and, if the weather permits, remove the lights entirely during the day, leaving a chink of air on all night. A dusting of soot round the pots will be very beneficial to the plants.

Calceolarias.—The same remarks apply equally to Calceolarias, only that in this instance green fly is the chief enemy which must be held in check. As weakness invites attacks from insects on all plants, every means must be taken to keep them in a good, healthy condition.

The Hardy Fruit Garden.

Strawberries.—If through stress of work or weather conditions the planting of young Strawberries was delayed, no time should be lost in having this done, so that the plants may become established before the winter. Should the ground not be sufficiently moist when the plants are put in, they must be given copious supplies of water until the roots have taken hold and become established. Autumn-fruiting varieties must not be neglected. The runners should be removed and the ground kept free of weeds. Perhaps the greatest enemy of these late-fruiting sorts is red spider, and if the plants are allowed to become infested, it is next to impossible to get rid of the pest, particularly at this season of the year.

JOHN HIGHTATE

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

DAFFODIL NOTES AND QUERIES.

AS one of the many readers of THE GARDEN who follow the Rev. J. Jacob's notes on the Daffodil, I venture to hope the following notes and queries may not be without interest. In September, 1911, I formed two beds, each 5 feet wide and 20 feet long; they were dug out of solid gravel to the depth of 2 feet 6 inches, the gravel removed, the subsoil loosened, and were made up with maiden loam and a sprinkling of leaf-mould; and quarter-inch bones were used at the time of planting the following bulbs:

Name of Variety.	Bulbs planted September, 1911.	Bulbs taken up July, 1914.	Increase per cent. in 3 years
<i>Triandrus hybrids</i> :			
M. Hume x T. albus	15	35	133
<i>Poets</i> :			
Almira	12	39	225
Chaucer	6	23	300
Comus	6	29	400
Dante	6	17	200
Horace	6	39	550
Homer	6	24	300
Musidorus	6	21	250
Recurvus	12	73	500
<i>Trumpets</i> :			
P. R. Barr	15	45	200
Victoria	10	61	500
W. P. Milner	20	79	300
Queen of Spain	20	40	100
King Alfred	6	29	400
Santa Maria	12	28	133
Mme. de Graaff	24	98	300
Weardale Perfection	6	29	400
M. J. Berkeley	25	39	50
Grandee	12	48	300
Henry Irving	10	59	500
<i>Incomparabiles, Barri and Leedsii</i> :			
Mrs. Langtry	20	94	350
Lulworth	12	84	600
Mrs. C. Bowley	12	61	400
Princess Mary	15	34	120
Hyacinth	12	61	400
Cirlet	3 (1 died)	4	33
Fairy Queen	12	60	400
Waterwitch	12	40	230
Frank Miles	12	75	500
Flora Wilson	12	38	215
Molly M. (seedling)	36	133	266

They were planted with a view to cross fertilisation and raising of seed—but of that I am not now writing; but last July they were dug up, with the results shown in the accompanying table. I am not sure how far those results are normal. When planted the bulbs were first size, and were obtained from one of our leading Daffodil houses. I may say smaller offsets are not counted, only bulbs of flowering size. For instance, I find on reference to my notes that the row of King Alfred, originally six bulbs, produced thirty-three flowers this season, and when dug up I found twenty-nine bulbs, all fit to plant separately; they are not, of course, all the same size. And now for my first query: What is the length of life of a trumpet Daffodil bulb? The original bulbs, I take it, would have been three years old at least, possibly more, when planted (that is, presuming they had been produced from offsets; if from seed, they would have been at least nine or ten years old). They have since produced offsets, some of which are three years old, and they themselves must be six or seven years old. Query No. 2: Those offsets being detached, will the original bulb, if planted, again set to work to produce more offsets, and, if so, for how long will this continue? I presume the oldest of the offsets will produce finer flowers than the old mother bulb (as I will call it); but I am not sure of this, so will call this Query No. 3. I am replanting my Poeticus this month; what assistance by way of manure can I give them? (Query No. 4.) I have

bastard-trenched the bed so that the bottom 12 inches of soil is now on top, and that would not appear to have been reached by the roots of any of the Daffodils. Is well-rotted cow-manure advisable if put well below the planting depth? (Query No. 5.)

The bulbs seem to have revelled in their conditions; they are enormous—certainly very much larger than normal. In taking them up I searched carefully for ravages of Merodon fly, but I only found five bulbs rotten or damaged, and they would appear to have been attacked by a cockchafer grub, two of which I found in the half-eaten bulbs. Basal rot accounted for the dead bulb of Cirlet (in 1912). All of the bulbs have given fine crops of flowers except M. J. Berkeley; this appeared to have yellow stripe badly the first year, and only gave me about six flowers. The second year I had ten and this year eighteen flowers, and the foliage was almost normal; but I understand it is a shy bloomer and its constitution not of the best, so I am doubtful if I shall replant it.

Southampton. HERBERT E. MOLYNEUX.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET PEAS DAMAGED (A. E. P.).—We do not see any trace of damage by insect or bird. The dwarfing of the flowers appears rather to be the result of a check to the growth, perhaps due to something amiss at the roots.

RUST ON HOLLYHOCKS (M. A. T.).—There is no certain cure for rust on Hollyhocks, but they can be kept fairly free from rust if grown from seed every year and the seedlings sprayed with a rose red solution of potassium permanganate from time to time.

SIX ANNUALS (Mrs. E. C.).—You do not say whether tender or hardy annuals are required, and if you are contemplating exhibiting in a competition class, this may be important. In these and similar cases much depends upon the wording of the schedule. *Nigella* Miss Jekyll, *Marigold* Orange King, *Godetia*, *Clarkia*, *Phlox* Drummondii, *Shirley* Poppy, *Rocket* Larkspur, *Scabiosa atropurpurea* varieties, *Sweet Peas* and *Eschscholtzia* in their best forms would be a good set to select from. Stocks, of course, are good, but if your soil is very heavy they may not respond quickly. Sow in March in well-prepared soil, and sow thinly if you desire good plant development and fine flowers. You had better use some soil fumigant and destroy the slugs during the coming winter. If you can give protection or have a sheltered garden, the Potatoes could be planted late in March or quite early in April. For clay soils, however, it is better to plant well-sprouted tubers in mid-April, as these often surpass those planted earlier in the open. Sow Carrots and Turnips in the first half of April; the Beans about the same time or a little later. The season, however, is a greater factor in the case than the time of planting, and late spring frosts are most trying. The leaf sent appears to be of the Balm, but a complete flowering specimen is necessary to enable us to determine.

TREES AND SHRUBS.

CULTIVATION OF NORTH AMERICAN GINSENG (Hong).—The Ginseng (*Aralia quinquefolia*) may be increased by two methods—by seeds and by root cuttings. When the first method is practised, the seeds are collected and sown in October; and when roots are used, sections half an inch or less in diameter are planted at the same time. The best soil is a light, friable loam, rich in humus. It must be deep and well drained, although permanently moist. Heavy soil is not suitable. The cuttings are planted about eight inches apart each way, and seeds

are sown with the object of thinning the seedlings to the same distance. Shade from bright sun is essential, and it is necessary to keep the soil about the plants clean by using the hoe several times during the year. The roots are lifted about September or October.

FRUITS OF PYRUS (E. B. J.).—The fruits of *Pyrus* (*Cydonia*) japonica have a strong flavour and odour, so that they are unfit to eat raw. A fruit or two in Apple tarts increases the flavour. They make an excellent jelly, though some people object to the austere flavour. The *Malus* (Crab) family make an excellent jelly, the flavour of which is softer to the palate than that of the Japanese Quince, *Pyrus japonica*.

THE GREENHOUSE.

TREATMENT OF HYDRANGEA (H. W.).—Do not prune back the shoots that have not flowered, as most of them should bloom next year. It is rather late for potting the Hydrangeas now, and if they require larger pots it would be better to wait until the spring. Still, you might give them a dose or two of liquid manure; the first should be applied as soon as possible, for on no account must it be continued later than the middle of September. The name of the flowering plant is *Clerodendron fallax*.

TREATMENT OF SCHIZANTHUS (E. O.).—Your plants of *Schizanthus* that have flowered this season will be quite useless for another year. Seed may be sown now, and the young plants should, when large enough, be potted singly into small pots, from which they ought to be shifted into pots 4 inches in diameter before winter. Then, early in the year, they can be put into those in which they are to flower. Failing conveniences for growing them during the winter in this way, the seed may be sown next February or early in March, and the young plants will then make rapid headway and form a good succession to those sown in autumn.

PALMS IN BAD CONDITION (E. O.).—There are not many Palms that will succeed in a cool conservatory, and if your query refers to *Kentias*, which we presume is the case, as they are so generally grown for decorative purposes, they require a little more heat than that to be seen at their best. Added to this, where they are cultivated in quantities for sale they are grown under very hot and moist conditions, in order to obtain effective-sized plants as soon as possible. The result of their tender upbringing is then quickly seen when they are placed under more adverse conditions. There is yet another important factor in the matter, which is that your plants may be starved at the roots—not, perhaps, that they need larger pots, but an occasional dose of one of the concentrated manures so much used may help to remedy the trouble. Palms that may be grown under the coolest conditions are *Rhapis flabelliformis*, *Chamaerops excelsa*, *C. humilis* and *Corypha australis*.

KITCHEN GARDEN.

FUNGUS ON MUSHROOMS (Enquirer).—We fear it will be impossible to kill stray fungus without damaging the Mushrooms, and think it would be best to clear the whole lot out and start afresh after thoroughly disinfecting the houses with carbolic or hot limewash.

SCARLET RUNNER BEANS ATTACKED BY INSECTS (R. F. L.).—Inject carbon bisulphide into the soil about the roots of the attacked plants at the rate of 1oz. to the square yard of soil. The fumes of this substance are deadly to all insect life and do not injure the roots of plants.

POTATOES ATTACKED BY BLACK SCAB DISEASE (H. E. I.).—The Potatoes are attacked by the Potato tumour or black scab. It would be best to refrain from growing Potatoes on the infested soil for several years, and, when Potato-growing is resumed, to select only varieties immune from the trouble. Meanwhile you must notify the Board of Agriculture, Whitehall Place, S.W., of the occurrence of the disease. A penalty attaches to failure to notify this to them, and they will advise you what to do. The disease is very infectious to Potatoes.

FRUIT GARDEN.

APPLE SHOOT FOR EXAMINATION (Constant Reader).—There is nothing on the shoots of the Apple sent to indicate the cause of their death. Possibly the tree is attacked lower down by canker or by some boring insect; but the cause, whatever it may be, is connected with a failure of the water supply.

APPLE TREES NOT DOING WELL (Argyllshire).—Something is wrong with the water supply to the young Apple trees, or they are growing in a draughty place where water is lost more rapidly than it can be supplied. We think it would be well to mulch the trees and see whether this would not improve their growth.

EARWIGS DEVOURING PEACHES (G. M.).—There are no more troublesome pests to get rid of in the garden than earwigs and ants. This is especially so when ripe fruit is their prey, as then it is not possible to apply drastic remedies without damaging the fruit. The two old-fashioned remedies are still the best, and if their application is persevered with they are effective, namely, a flower-pot on a stake with a bunch of dry hay or moss in it for Dahlias and other plants to which the earwigs are partial, and the hollow stem of the Bean stalk or any other hollow stem placed among the branches of fruit trees when fruit is attacked. To succeed means serious and long-continued attention. A large number of hollow stems should be placed in the trees, and the earwigs blown out into a vessel of water night and morning.

THE GARDEN.

No. 2235.—Vol. LXXVIII.

SEPTEMBER 19, 1914.

NOTES OF THE WEEK.

Our Sub-Editor Joins the Army.—It is with considerable gratification that we announce that our Sub-Editor, Mr. H. Cowley, has answered his country's call, and has joined the Polytechnic Corps of the London Rangers for as long as the war lasts. As an old Kewite, and as Sub-Editor of THE GARDEN, Mr. Cowley has made many friends, and we know that they and our numerous readers will join with us in wishing him every success and a safe and speedy return.

The National Rose Society and the War.—As the autumn show of the National Rose Society has been abandoned for this year, the Council of the Society, at its meeting held on the 8th inst., unanimously decided to send a donation of fifty guineas to the Relief Fund which is being raised by the Society's Royal patroness, Queen Alexandra.

A Beautiful Herbaceous Phlox.

—With so many excellent and charming Phloxes to select from it is difficult to pick out one that is much better than many others. That illustrated on this page, however, has done so well with us for several years that it certainly deserves special mention. Unfortunately, it has the unwieldy and foreign name of Hanny Pfeiderer, but we must not let this blind us to its excellent qualities. It is a strong and sturdy grower, attaining a height of about three feet, and its large, symmetrical flowers are produced freely in bold heads. Their colour is cream, changing to salmon, and each has a decided crimson centre that contrasts well with the outer colour of the segments. Plants can be purchased cheaply from dealers in hardy plants.

Geum Mrs. Bradshaw.—This beautiful scarlet border plant may be easily increased by sowing the seeds as soon as they are quite ripe. The soil must never be allowed to become dry before the plants are well through the surface, when they may be carefully pricked into boxes of good rich soil. If space is available, they should be allowed to remain in a cold frame during the winter.

Nicotiana affinis as a Cut Flower. Miss Jekyll sends us the following timely note on the sweet-scented Tobacco: "If this beautiful flower is cut in the evening when the bloom is expanded, it does not close again when put in water in the house; moreover, any of the flowers that may

be only in bud will open and remain open. It should have the addition of some rather solid foliage. Bay is always beautiful, and the rather pale green colour and solid texture of Skimmia are specially becoming. It remains many days in good order."

Beautiful Flower-Beds.—Some large flower-beds, charmingly filled, have been greatly admired in a public garden in Hampshire during the present

Potato and Corn Crops in Great Britain.—The monthly Agricultural Report, just issued by the Board of Agriculture, shows that the Potato and Corn crops in Great Britain are this year well up to the average, and that practically all corn has been harvested in good condition. Summarising the returns, and expressing an average crop by 100, the condition of the crops on September 1 indicated probable yields per acre which

may be denoted by the following percentages: Wheat, 104; Barley, 99; Oats, 95; Beans, 101; Peas, 93; Potatoes, 102; Turnips and Swedes, 96; Mangolds, 99; and Hops, 109.

Vacant Land Cultivation Society.

—At a time such as this, when everyone is urged to cultivate as much food as possible, we are pleased to receive the annual report of the above society. Founded in London in 1908 by the late Mr. Joseph Fels, the society has already done valuable work in securing vacant plots and instructing suitable men to cultivate them to the best advantage. Since the war broke out, strenuous and successful efforts have been made to secure further land, and an appeal to seedsmen and gardeners for seeds and plants has met with a good response. The society is, however, badly in need of funds. Full particulars of its work can be obtained from Mr. H. J. Wright, 180, Fleet Street, London, E.C.

Dividing Christmas Roses.—The Christmas Roses are generally known by gardeners to be impatient of root disturbance, the result of which is almost certain to be the non-production of flowers the following year, especially if done in a careless way or at the wrong time. If possible, they should be left undisturbed; but as there are times when it is necessary to lift and divide, it may be of value to know that now is the best time.

Great care should be taken to extract the roots intact. In dividing the plant, let the rhizome be cut through with a sharp knife; then with two handforks pull the plant apart, endeavouring to keep with each part some of the strongest outside crowns. In replanting do not put manure near the roots, but a little decayed leaf-soil and grit will be helpful in encouraging the formation of new roots.

A YOUNG PLANT OF A BEAUTIFUL DWARF HERBACEOUS PHLOX. (See note on this page.)

summer. The groundwork in the centre was composed of Gazania splendens. Over this at 3 feet apart were half-standard Fuchsias of the varieties elegans, Lena and conspicua, respectively. The whole was edged with a broad band of Alyssum minimum. The rich orange-coloured flowers of the Gazanias, dark centres, and silvery reverse of the green leaves made a very rich and pleasing display.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Flowers for Wounded Soldiers.—At a time like the present, when all classes of society are anxious to do something for the Empire, I should like to appeal to the generosity of my fellow gardeners. There are now in London four general hospitals dedicated to the use of the Territorial Forces, that voluntary line of defence whose patriotism has hitherto saved us from the necessity of conscription. These hospitals are anxious to obtain plants and flowers, so that a bright and cheerful atmosphere may be maintained in the wards, where pain is bound to be paramount at this unhappy time. It occurs to me that exhibitors at the Royal Horticultural Society's shows at Vincent Square might like to send some part of their exhibit, either plants, cut flowers or fruit, to these hospitals at the close of the day, and that nurserymen and amateurs as well might care to join in this really charitable object. I should be

of £90 was realised and given, without any deductions whatever, towards the National Relief Fund." These are examples that might well be followed in other districts where flowers are abundant.

The Nemesia Sown in May.—The beauty and value of the Nemesia is well attested to in the photograph and note appearing on page 434. And I presume from their mature appearance they are the product of early sown seed, perhaps March, though no date is given. It may interest some to know we have a batch of plants about half grown to their usual size, with a good sprinkling of flowers as a result of being sown the first week in May in a cold frame. The light was kept on until after growth had commenced and then removed. This treatment and the removal of the first showing of flowers kept them back, with the result that they will be at their best about the end of this month (September), and, of course, continue in good order until stopped by frost.

—C. T., Highgate.

Lewisia Howellii in the Moraine.—It is interesting and valuable to observe from the

prospects of the immediate future. It has been confided to me by heads of firms of considerable importance that not only have orders dropped to a point of insignificance, but the settlement of accounts has been neglected by regular and esteemed customers to such a degree that the difficulties of the situation have become extreme. The long credit expected and allowed in all the trades connected with gardening has always been a problem fraught with trials for those upon whose shoulders rest the burden of organisation and control of business; but now, of all times, delay in settlement of accounts strains most seriously the powers and resources of the business man who is striving quietly but doggedly to keep things on the move. My belief is that those who have a real love of gardening in their hearts have also the grace of goodwill, and that a word of intimation that the payment of an account will relieve a tradesman's anxiety, and maybe help him still to keep his men employed, will not fail to achieve its object. The readers of THE GARDEN are not immune from the sacrifices imposed upon the country by the war, and no one may be blamed for exercising wise economy; but it seems to me that those who have been accustomed to obtain much of their enjoyment from their gardens may justly consider that by supporting their tradesmen as generously as they are able, they will be performing as commendable acts as by subscribing to relief funds. It is not the nurseryman and seedsman alone who need the kindly consideration of the patrons of horticulture. The builders of greenhouses and the heating engineers employ many hands, and theirs is a trade allied to the gardening world that is feeling the pinch sorely. At any time it is within the reach of only the well-favoured classes to erect extensive ranges of glass houses; but if such as have the means will arrange for extensions and improvements they may have had in contemplation to be put in hand at once, instead of postponing the work until the war is over, it may mean wages instead of no wages to some British workmen. The usual thing in the autumn is to look round and see what is wanted in the way of new implements. A new spade or fork, a barrow, a spraying machine, new clothes or hand-lights are among one's usual requirements at this season. Let us hope the orders for these things and for the usual garden sundries will not be withheld unless it is really imperative to do so, for it will be an added catastrophe not only to the individual tradesman, but to the workers and the nation, if trade is allowed to stagnate, with the consequent closing down or bankruptcy of business houses. My final word is in the ear of the trade themselves. Remember the power and importance of advertising. In flourishing times it is necessary to woo trade through the medium of advertisements. It is even more imperative when things are slow to fan the enthusiasm of possible buyers by judicious exhortation, and while realising the anxiety to shun every avoidable expense, I venture to opine that a business that is built up or largely maintained by the aid of advertisements demands advertisement now, and without it it is bound to languish. Let it not be thought by any reader that I assume the privilege or audacity to dictate to either buyer or seller as to what should or should not be done; but if, mixing closely as I do with traders and workers, I can indicate the needs of the moment and help to keep things moving, my epistle will have done no harm.—HEATHER BELL.

GATHERING ROSES FOR THE PRINCE OF WALES' RELIEF FUND. A SCENE IN MR. HICKS' NURSERY.

pleased to make all arrangements for collection and distribution in London if intending donors would communicate with me, either at Balls Park, Hertford, or at 34, Eccleston Square, S.W., and as regards country contributions, I would send the address of the four hospitals in question to enable parcels to be sent direct.—B. S. FAUDEL-PHILLIPS, *Balls Park, Hertford*.

Roses for the Relief Fund.—Mr. E. J. Hicks of Hurst, Twyford, Berks, has undertaken to give 1,000 Roses every Saturday so long as the season lasts, to be sold in Reading in aid of the Prince of Wales's Relief Fund. The first Saturday's sales brought in £15 15s. 8d., the highest amount, £2 9s., being collected by Miss M. Chalker. Mr. W. Easlea, Danecroft Rosery, Eastwood, Essex, also writes us as follows: "I am happy to say that one of the leading ladies of Southend volunteered to sell 2,000 Rose blooms which I offered. The sanction of the Mayor was obtained, and some scores of young ladies vied with each other in this work of love for their country. The 2,000 blooms were quickly disposed of, and another 1,000 sent in, with the result that a grand total

note by Miss Brown on page 434, August 29, that *Lewisia Howellii* is flowering for the second time this year in her moraine at Longformacus, Duns. I grow *L. Howellii* here also in a whinstone and lime moraine, but it has shown no tendency to bloom a second time. It flowered well in the spring, but it was left purposely uncovered during the past winter to see how it would stand in a moraine as compared with its conduct on rockwork. It looks as if the free drainage of the moraine would be a panacea for the loss of many plants through rotting off at the neck in winter in wet districts such as the West of Scotland. It is considerably drier at Duns, but the glass overhead may still be a desirable precaution.—S. ARNOTT, *Dumfries*.

The War and Trade.—Since my note headed "Help the Trade," which appeared in last week's issue, was written, I have been in contact with a good many people engaged in the horticultural and allied trades, and I have found, in spite of a most earnest desire to keep workmen employed, a great deal of real anxiety is felt in regard to

WINTER VEGETABLES AND SALADS.

WITHOUT in the slightest degree partaking in the sensational and extreme views which urge that the lawn should be converted into an Onion-bed, and that Cauliflowers in pots should occupy the conservatory, I fully agree that the unusual circumstances of the moment and the possibility of even grave emergency in the future justify, and indeed demand, that some special effort shall be made to produce as much foodstuff as possible; and every owner of a garden will be doing his duty by growing what vegetables and salads he can, either for his own consumption or to give to poorer folk, upon whom the burden of financial distress is likely to press heavily during the coming winter.

THE GARDEN has already given its readers sound advice in regard to the main crops that may be seasonably sown or planted during this month; but it may be that some will like to try their hand at a few things out of the ordinary run, and there are some kinds that are decidedly worth attention, especially where means of protection or facilities for forcing are available. One of the simplest things to grow is American Cress or Land Cress; but it is a decidedly useful component for winter salad, the leaves being charged with juices that are an excellent tonic. All that is necessary is to sow the seed in shallow drills in a position where a fair amount of moisture is afforded the growing plants. Keep the surface of the bed hoed, and as soon as large enough commence to pick the leaves. Corn Salad or Lamb's Lettuce is another very easily grown subject that affords a pleasing variation to the salad-bowl. Seeds may be sown either broadcast or in drills on any available plot of ground, and, by thinning as soon as the earliest plants attain four or five leaves, quite a small bed will yield a prolonged supply. Chervil sown on a south border or in a corner that affords some protection from severe weather will become useful for flavouring soups, minces, rissoles, &c.; and even now it is not too late to sow Winter Spinach in places where some protection, if only a little loose litter, can be afforded when bad weather comes.

Use of the Spare Frame.—Now is a time when the owner of a spare frame may with advantage try his hand at intensive cultivation on the French gardening system. A hot-bed should be constructed of slightly larger circumference than that of the frame, and as soon as the first violent heat subsides, the frame should be filled with well-prepared soil to a depth of 9 inches or 16 inches and made fairly firm. It is possible with such a frame to grow three crops simultaneously.

First sow Radish seed broadcast over the whole surface. Next draw drills 9 inches apart and sow thinly seed of a good Shorthorn Carrot; finally plant with a dibber Lettuces (of Cabbage variety) not less than a foot apart each way. The Radishes will rapidly attain a usable size, and can be pulled before the other crops require the space. The Lettuces should be cut while still young, and therefore tender, and thus the Carrots will be enabled to develop into a useful crop. An alternative combination would be Turnips in place of Carrots, and early forcing Cauliflowers in place of Lettuces. Several seedsmen offer specially selected,

A CORNER OF THE SPEAKER'S ROCK GARDEN AT CAMPSEA ASHE. THE GARDENS WERE FULLY DESCRIBED IN OUR ISSUE FOR SEPTEMBER 5.

quick-growing varieties of these things that are adapted to this system of culture. Where greenhouse space is available, French Beans can be sown now and grown on in pots to produce good winter crops, and space under stages should, during the winter, be utilised for forcing Rhubarb or Seakale, bedding the roots in a mixture of soil and manure, and using mats, canvas or even stiff brown paper to exclude light. Earthen chimney-pots may be placed over Rhubarb roots, Seakale or Chicory in the open beds; and if the space between the pots is filled with manure, leaves and straw, the crop will mature earlier.

HEATHER BELI

CHRYSANTHEMUMS IN SEPTEMBER.

THE plants are now making rapid progress, the wood is also hardening well owing to the recent hot weather, and so cultivators will be well advised to feed liberally all plants before they are placed under glass. One week of feeding in the open air is of more advantage than two weeks under glass, because any undue forcing of the growth will only result in weakening the stems of plants that are being grown for the production of late flowers. The feeding of those plants for the production of large blooms at the end of October and during November for greenhouse and conservatory groups must be continued after the plants have been placed under glass, as the flower-stems are firm and the strength of the plants will go to these stems and buds.

Top-Dressing and Feeding.—

A few years ago it was considered sufficient if one good mulch was put on; but in these days the work of top-dressing is continued from the early part of August to the end of September and even later. Instead of putting on a thick layer of soil and manure, the cultivator should sift through a half-inch mesh sieve some good broken loam that has not been previously used and some quite rotted manure in equal proportions. An approved chemical manure should be mixed with the loam, and organic manure according to the directions given with it. The best way to mix is to pass all through a sieve together. Sprinkle just sufficient of the compost on to cover the roots showing on the surface, and always water through a rosed watering-can. In the course of a week, perhaps less, another sprinkling may be necessary, and in this way a mass of healthy roots will be secured on the surface, which can be fed regularly.

Suckers.—The surface-dressings always encourage suckers to grow, and these must be carefully removed while quite small until the latter part of October. Sometimes they may be broken out of the soil without much trouble; but

if a knife is used, care must be taken not to sever the roots at the same time.

Stem Shoots.—These, too, grow rapidly at this season. They must be rubbed off regularly from the axils of the leaves, as they rob the plants of much strength if left to grow to a large size. Some varieties, notably Hon. Mrs. Lopes, do not produce soil cuttings freely, and do not bear stem ones at the base. Where this is the case, the cultivator should leave the shoots on after the end of September for insertion as early cuttings, in case better ones cannot be procured.

Syringing the Plants.—This is very beneficial if done about five o'clock in the afternoon on warm days. Especially is it helpful in cases where the wood is hard and the stems of the buds too. The water must be tepid; then the buds will swell freely. The syringing tends to keep the foliage free from black and green aphides without the use of insecticides. AVON.

CLEMATIS MONTANA ON A SPRUCE.

THE illustration on this page shows what pleasant surprises a garden will provide for its planter if now and then he will let a plant have its own way and make and carry out its own arrangements. It must be twenty years since this Clematis was planted at the foot of a Walnut tree that overhung the road and filled the space behind the wall just to the left of the lodge. In the Walnut season it made a target for every small boy who could find a loose stone in the road. Sometimes the stone hit a nut and fell with it into the road again, but more often the stones missed their mark and fell into the garden, and it was scarcely safe to remain in that part of the garden except during school hours. This trouble, added to the fact that the Walnut shaded the best part of the border and was too big for its place, led to its being cut down; but as the Clematis was not injured in the operation we trained it on to the wall, and it soon ran all along the top and hung down, as can be seen in the illustration, into the road, to be a real Traveller's Joy when in full flower. Then it decided for itself that it would climb into the Spruce, and now it has reached to the very top of it, and the trails that hang down flower beautifully each May. In early autumn and onward till the winter, winds scatter the fluffy seeds, give a sort of encore turn, and once again make a white pillar of the tree. The root of this Clematis is close behind the wall in the very left-hand of the picture, and the stem is by now quite a tree trunk; and looking at it and the pillar of snow nearer the gate it is quite hard to believe the two are parts of one plant. The combination of the dark green of the Spruce and the white flowers of the Clematis is a very pleasing one, and where trees to which no special value is attached exist, the Clematis might be planted for the purpose. I should like to see the curtain of blossom hang right down the wall, but passers-by think otherwise, and shorten it up as high as they can reach. What pedestrians leave is further pruned by folk in carts, so it remains at a regular height from the ground like trees in a park browsed by cattle. Anyway, the Clematis flowers have provided a substitute for the vanished Walnuts without endangering my skull. E. A. BOWLES.

NOTES ON CARNATIONS.

DIFFERENT people have different times for planting out layers to stand the winter and bloom the next year. I like to plant in the second, or at latest in the third week of the present month. The reason is that the layers are then well rooted and transplant with efficient balls, also that there is time for the plants to be thoroughly established before the winter, and consequently in a condition to withstand the evils of that season. The principal points to observe in planting are

produce single blooms of the best quality, but it must be understood that close planting and layering are for decorative purposes only.

Plants to be Wintered in Pots may, and should, if at all convenient, be seen to at once. If the plants are to be satisfactory for planting out in spring, it is important that the flower-pots in which they are to be wintered should be large enough to enable them to gain strength, and the very weakest only be placed in 3-inch pots, stronger ones in 4-inch, and very strong layers in pots of a slightly larger size. If wet weather sets in, the plants should be protected by sashes at once and kept as dry as it is possible to keep them to permit of a slow growth. It is invariably at this period that disease attacks the foliage, though it may be later until it is apparent, and wet or damp is invariably the predisposing cause.

Seedling-Raising is an engrossing side issue, and seeds will now be quite ripe on plants in the open. The seed-vessels should be preserved with the seeds intact, in which they can be perfectly well kept till the spring. Malmaisons still in frames must not be left there so long as to become victims of leaf disease. The watering of these is by far the most important part of their management now and onwards, and no more water should be applied than just enough to preserve them in perfect health, nothing in the way of growth extension being attempted. If the plants can be stood on a cool base, it is much to be preferred—owing to a certain amount of moisture being conserved in the under part of the pots—to standing them on open trellises.

Late-Flowering Plants must be treated to enough moisture at the roots to favour the due development of the flowers, and the atmospheric conditions should similarly be favourable to that end. But forcing of any kind only ends in weakened stems, and blooms flaccid and wanting in colour. The plants after flowering are worthless. The time is one of quiet waiting generally as regards Perpetuals, though some growers have a very profuse display already, which will, no doubt, be discounted by a breakdown in the supply of bloom later. I have still numbers of flowers on second year plants, and these are so promising that

unbloomed stock would appear to be almost a superfluity. Meanwhile the latter are allowed to come along slowly to make sure of a good midwinter display. We have quite a nice lot of planted-out material, some of which will, before this appears, be lifted and potted for house decoration later, and this simple phase of Carnation growing might well be considered on its merits by those whose means do not allow of special treatment. In my next instalment I shall hope to have a good deal to say about Perpetuals.

Prestonkirk, N.B.

R. P. BROTHERSTON.

CLEMATIS MONTANA GROWING OVER A SPRUCE TREE IN MR. E. A. BOWLES' GARDEN AT WALTHAM CROSS.

to plant shallow rather than deep, the Carnation being suffruticose, and therefore subject to disease in the stem when that is buried unduly. Then, provided the soil has been thoroughly pulverised and in suitable condition at the time of planting, it ought to be made very firm round the plants. If these are very strong or tall, a short stick should be afforded each to steady it until established. In heavy soils in which moisture fails to pass away rapidly, it is worth forming the beds in a convex form rather than flat. Beds intended for effect may be planted much closer than those which are expected to

THE GIANT ASPHODELS.

AMONG hardy perennial herbaceous plants the Giant Asphodels occupy a pinnacle of their own, an impregnable position from which they are not likely to be displaced. To realise this in fullest measure, one has to see them rightly placed in the garden in the heyday of their summer beauty rearing their lofty spires to 8 feet or 12 feet high, when, by reason of a stateliness which raises them head and shoulders above all other flower plants of their time, they simply impel admiration. In other groups of herbaceous plants—in Lily, Larkspur, Sunflower and Torch Lily—fine floral effects and not a little picturesqueness are available. These, however, have a beauty apart which does not come into competition with the noble Asphodels, and were it otherwise it could not displace them from their high estate. In a word, therefore, they are unique, ranking high in the estimation of those who garden chiefly in the open air, and higher still with those who, realising their fuller value when amid suitable environment, so dispose them in shrubbery or woodland that fresh pictures are added to the landscape worthy of the plants themselves. For such gardening as this these Asphodels are well suited, none appearing to greater advantage than those seen springing from a groundwork of dwarf shrubs or in near proximity to Holly or Yew, which, apart from their protective influence, mirror them into fuller life and beauty, constitute a fitting foil—a frame it may be—to the picture-making effects of the whole. For the dark foil mentioned, the white *Eremurus himalaicus* is peculiarly well suited, the others appearing to greater advantage where light filters on to them from behind. It is amid such scenes, too, that the plants admit of free grouping, and while finding a congenial home are freed from the frequent risks of digging, hoeing and the like, inseparable from the ordinary border. For the latter I would only recommend the smaller-rooted species, as *Bungei*, and *Shelford*, those of the robustus type having a greater root spread—the rope-like thongs radiate like the spokes of a cart-wheel from a common centre—requiring more space, with immunity from disturbance.

Adaptability and Grouping.—Interspersed with the foregoing remarks will be found suggestions as to the adaptability of these plants for shrubbery and woodland. In such places they not only display themselves to greater advantage, but receive protection from high winds, and, best of all, from the disfiguring and sometimes damaging effects of spring frosts. For such as *E. robustus* and its varieties and *E. himalaicus*, the early risers of the group, such protection is more necessary than for those coming later. Apart from this protection, both shrubbery and woodland have an influence for good on the longevity of the floral display, the flowering lasting longer in such than in the fuller sunlight of the border. In reality I do not advise the planting of these

Eremuri in the border, for reasons already stated. For the thousands of those who possess no woodland and comparatively small shrub borders, however, I would suggest the selecting of a place apart where comparative immunity from disturbance would be ensured. In such, with a south-west exposure, the plants would be safe. In grouping, it is only necessary to observe informality, with abundant room for development. "Massing," so called, is to be discouraged, and in place thereof that easy disposal of the plants which borders on the natural. Where dwarf shrubs are used as a groundwork, these naturally correct attempts at more formal planting, besides playing an important part otherwise. Where planting is being done over a large area, the individuals need not be nearer than 5 feet or 6 feet asunder.

Soil Requirements.—These *Eremuri* are not fastidious as to soil, and are of quite easy cultivation in all classes of loam provided they

GARDEN FRITILLARIES.

(Continued from page 451.)

Fritillaria pontica.—There is a small group which always gives me pleasure to look at because of something about the flowers that appeals to me as being "blue-blooded." In colouring they are insignificant. In fact, *pontica*, the best of them, is almost entirely pale green, but their large, long bells, generally solitary, are very handsome in shape. They have no chequering, but a rich, glaucous bloom covers the flower, and the stems are taller and more slender and rigid than in some of the commoners of the family. With *pontica* I should place *Elwesii* and *acmopetala*. They are good perennials, and have showy, erect seed-pods.

F. Thunbergi is an interesting little Japanese species, seldom seen in gardens, yet almost a weed with me—it spreads so easily. It represents a very distinct section, which has slender leaves

A COLONY OF SEEDLING GIANT ASPHODELS OR EREMURI.

are well drained. One of the finest solitary examples of *E. robustus* that came my way a dozen or more years ago was five years planted in light sandy soil and measured 11 feet 6 inches high. Warmth of soil—that promoted by good drainage—appears to be essential, the plants abhorring clay soils of a close, tenacious character. For the giants of the race, in addition to depth, a considerable superficial soil area should be prepared, seeing that the great roots extend to 3 feet or more from the central crown. To sum up, well-cultivated, well-enriched, amply drained positions of 6 feet diameter should be prepared, and in such they will be happy for years. For those of lesser vigour and root spread, one-half of this diameter will be enough. All, however, merit generous treatment and repay it. Next week I hope to give some particulars of the various groups into which these noble plants can be conveniently arranged for purposes of cultivation. E. H. JENKINS.

(To be continued.)

with curled, hook-like tips, and the little masses of grey foliage that it makes are really more ornamental than its flowers, which are rather lacking in character. The Fritillaries seem full of puzzles to the botanists. On one hand they can hardly be separated from the true Lilies; on the other, they show such differences in essential characters that many botanists would split them up into several genera.

F. discolor is one of these abnormal forms. It is an uncommon plant, thoroughly established with me, which has also been named *Korolkowia discolor*. It is handsome enough, and wins quiet admiration, but is not very showy on account of the large leaf-like, grey bracts which subtend the flowers. The star-shaped flowers are held almost horizontally on short stalks, and have a quiet colour-scheme of greenish yellow and crimson with crimson anthers. This flowers in early March, and grows about eighteen inches high. Like the rest, I have it in soil on the heavy side.

F. macrophylla is another strange plant we now recognise as a Fritillary, although Wallich named it *Lilium roseum*, and Lindley, *Lilium thompsonianum*. It bears a long panicle of rosy lilac flowers in April and May. Loam, leaf-soil and limestone are recommended for it, but I never succeeded in keeping it very long.

F. sarana (Linnaeus' *Lilium kamtschaticense*), the Black Lily, is another rather difficult plant both to place rightly in the herbarium and to grow properly in our gardens. The blackish maroon flowers, with yellow anthers, are very striking.

F. obliqua, however, which also has blackish, handsome bells, I do manage with success. I first saw and admired it in the garden of the Rev. Arthur Boscawen, and that prince of gardeners afterwards sent me a stock which gives me no difficulty in keeping, although I cannot say it spreads much.

F. aurea and **F. armena** are delightful little species, so cheap that everybody should plant them by the hundred. *F. aurea* is from the alpine pastures of Cilicia, and is a beautiful little subject for the alpine-house. *F. armena* also comes from Asia Minor, and small collected bulbs are generally sent out.

F. pyrenaica, from the Pyrenees, is an easily kept plant, and I like it for its graceful habit as well as for its rather dark bells. It grows about a foot high or a little less, and carries solitary fleshy bells, almost entirely purple maroon outside, but worth lifting to look at the glossy green within.

It is rather strange that while some of our easiest species come from Asia Minor and other places, with climates quite opposite in their general conditions to our own, yet when we get hold of the alpine species of Europe they often prove quite intractable. Twenty to thirty years ago the gardening papers used to ring the praises of the beautiful

F. Moggridgei, which makes sheets of yellow in the upland slopes of the Maritime Alps, and of its close relative, the plum purple *Burnati*. "Very easily managed," was the comment on them, and further particulars were not thought necessary; but I do not know a garden where they exist to-day, nor do nurserymen any longer list them. Who will tell us their secret?

R. W. WALLACE.

(To be continued.)

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Campanula Norman Grove.—A pretty hybrid Bellflower said to have resulted from crossing *C. carpatica* White Star and *C. tommasiniana*. As a matter of fact, there is little or no apparent influence of the cross save in the slight semblance of foliage to the last-named kind. The plant is barely 6 inches high, flowers blue, profusely borne above a neat habit. The flowers are horizontally disposed after the manner of *C. Stansfieldii*. Its best flowering season is said to be June, its present

flowering the result of stopping and late propagation. From Messrs. T. B. Grove and Son, Sutton Coldfield, Birmingham.

Amaryllis Belladonna speciosa purpurea.—

A very handsome, richly coloured form whose stems are also of an attractive colour shade. The variety is bold and freely flowered. From Messrs. Robert Veitch and Co., Exeter.

Lilium Biondii.—A very graceful new Chinese species whose reflexing, orange-coloured flowers are heavily spotted with crimson. The linear leaves are 3 inches or 4 inches long and thickly crowd the lower parts of the stems, which reach about four feet high.

Aster Amellus King George.—Quite the largest of the Italian Starworts to date, the flowers reaching nearly three inches across and of a good blue colour. In a word, the new-comer

A SPRAY OF THE NEW DWARF ITALIAN STARWORT, *ASTER AMELLUS KING GEORGE*.

should prove to the early border what *Climax* is to the late border. The *Lilium* and this Starwort came from Mr. Amos Perry, Enfield.

Gladiolus Lord Alverstone.—A rather handsome, well-formed spike with flowers of good substance, coloured a deep ruby crimson. From Messrs. James Kelway and Son, Langport.

Dahlia Lovely (Decorative).—The flower is of good size, and coloured a refined and pleasing yellow shade.

Dahlia Etoile Rose (Garden Cactus).—The predominating shade is pink, and very pleasing withal.

Dahlia Stella (Collarette).—Of pronounced scarlet and white colouring, very striking and effective. These were shown by Mr. C. Turner, Slough.

Dahlia Rotiier (Pompon Cactus).—A pretty and useful sort for cutting, the reddish florets having pinky white tips.

Dahlia Marguerite Phillips (Cactus).—The florets are somewhat broad and quite pure white.

Dahlia Kismet (Cactus).—A graceful variety in which the narrow, incurving florets are coloured a reddish carmine.

Dahlia The Swan (Cactus).—Quite pure white, with acutely pointed florets.

Dahlia Mrs. Edward Drury (Cactus).—The colour is reddish scarlet in a particularly handsome flower. These five were exhibited by Messrs. J. Stredwick and Son, St. Leonards.

Dahlia White Star.—A semi-double-flowered seedling from *Crawley Star*, also recognised as the *Cosmea*-flowered *Dahlia*. The white is quite pure in a flower of medium size. This variety should prove invaluable for cutting by reason of its purity and informality.

Dahlia Worth Star.—This is also of the same race, slightly more cupped and formal-looking, and coloured a rosy mauve with gold centre.

Dahlia Eden (Collarette).—We know of nothing in its section to equal this in purity and substance. The stem, too, is excellent, and carries the flowers well up. Both inner and outer florets are exceedingly chaste and pure. These three were shown by Messrs. J. Cheal and Sons, Crawley.

The foregoing Dahlias were adjudicated upon by a joint committee of the National Dahlia Society and the floral committee of the Royal Horticultural Society; hence are entitled to the first-class certificate of the former and the award of merit of the latter society.

NEW FRUIT.

Blackberry Himalayan Giant.

We did not see this variety, which was sent up from Wisley for inspection. From Messrs. Laxton Brothers, Bedford. Award of merit.

NEW ORCHIDS.

Cattleya Sybil variety Lord Kitchener (*C. aurea* × *C. iridescens*).—

A striking and beautiful novelty. Through the centre of the sepals and petals runs a golden band, from which point this

colour is suffused with salmon rose. The lobe of the lip is of rich crimson, the basal half of golden orange hue. A very remarkable variety. From Messrs. Hassall and Co., Southgate, N. First-class certificate.

Cattleya iridescens aurifera (*C. bicolor* × *C. Eldorado*).—Sepals and petals golden, the well-developed lip of rich purple. Exhibited by Messrs. E. H. Davidson and Co., Twyford. Award of merit.

Laelio-Cattleya Hyone McBean's Variety (*L.-C. Ophir* × *C. aurea*).—A charming variety in which the sepals and petals are golden, with a suffusion of salmon. The handsome lip is of rich crimson, freely reticulated with gold at the base. From Messrs. J. and A. McBean, Cooksbridge, Sussex. Award of merit.

All the foregoing were shown at the Royal Horticultural Hall on the 8th inst., when the awards were made.

GARDENING FOR BEGINNERS.

BEDS AND BORDERS FOR SPRING FLOWERS.

A FINE display of blossom may be obtained from bulbs and other flowering subjects in spring in a very small garden. Every year cultivators like to have some fresh feature in their gardens, and if they are not able to

A.—SHOWING DESIGN FOR DRY WALL AND BORDER.

make new beds, they can at least have fresh designs.

Old Stone or Brick Walls.—Where these are available—I mean really old walls more or less broken, as only such are suitable—the holes may be filled up with a mixture of loam and a small quantity of clay. The clay must be used to form cups in the face of the wall, where odd stones or bricks are removed, to help to retain the finer soil and the roots of the plants. Leaf-soil should not be used; it is too light and dries too quickly. Soil must also be placed on the top of the wall. Where walls are not now in existence, and material for them is readily available, they may be built to form a background in a suitable quarter, or as an ornamental division fence. The height of the wall should be in proportion to its surroundings and its length. If more than 50 feet long, it may be 30 inches high; if under 20 feet, 18 inches will be high enough. Mortar need not be used in the construction of these walls; they may be dry-built or with layers of ordinary soil between the stones or bricks. Such walls are splendid for facing up broken banks; then a nice wide border for plants can be made at the top as well as one at the foot, as shown at No. 1, Fig. A. The border may be filled with bulbs, early and late flowering Narcissi, with Snowdrops and Polyanthus at the foot of the wall, and a front bordering of Aubrietias. At the top, No. 2, Wallflowers, Aubrietias, double and single flowered Arabis and Sedums, Saxifrages and similar kinds of plants should be planted in irregular clumps. When well planted and the arrangement is good, these old walls and borders do not entail much labour in maintaining them in a satisfactory condition. The border, No. 1,

will be available for summer-flowering subjects in due course, and the wall, with its top border, may be easily furnished with a few additional plants.

Formal Beds.—In many gardens there is only space for long, narrow borders on each side of the path leading to the dwelling-house. These borders are so placed that all their occupants can be seen from the windows, and, according to the taste of the owner, they may be filled with brilliantly flowered bulbs or the more subdued tones of the Wallflowers, Polyanthus, Primroses, Aubrietias, Arabis, &c. No. 1 represents the dwelling-house; Nos. 2, 2, broad bands of Aubrietias; Nos. 3, 3, double Arabis, with dot plants of golden yellow Wallflowers. Or Nos. 2, 2 may be double Arabis; Nos. 3, 3, blue Forget-me-nots, with scarlet Tulips planted 1 foot apart each way. Many schemes of planting may be carried out. No. 4 represents

DESIGNS FOR BORDERS IN FRONT OF A HOUSE.

the path. Then there are isolated beds in gardens, and all the more important ones are round, oval or square in shape. Complicated or fantastic designs never look well; especially is this the case where the beds are small. The designs of Figs. C and B are given as guides only, as many other ways of filling the beds may be adopted. A red, white and blue bed may be had by planting Fig. C as follows: No. 1, blue Myosotis; Nos. 2, 2, white Tulips; Nos. 3, 3, scarlet Tulips. Hyacinths may be used instead of Tulips. No. 1, white Daisies, with the whole of the centre of the bed filled with Blood Red Wallflowers, is another scheme; or, No. 1, red Daisies, the whole of the centre blue Myosotis, with dot plants of white Hyacinths or white Tulips. Fig. B shows a raised bed. This is a good way of treating very heavy

soils, where the plants must be grown in them throughout the winter months. These beds have a very charming effect, and may be filled in various ways. The centre, No. 1, Polyanthus, mixed colours; No. 2, Aubrietias or Giant White Daisies—the red Daisies would clash with some of the colours of the Polyanthus. Wallflowers may be planted with Arabis as an edging. No. 1, white Hyacinths; No. 2, red Daisies, or *vice versa*—white Daisies and red Hyacinths. The latter are too formal for edgings. Arabis, Aubrietias, Myosotis and Daisies are the most effective as edging plants. G. G.

HOW TO TREAT TUBEROUS BEGONIAS AND GLOXINIAS.

TOWARDS the end of the summer the more forward plants of the above show signs of exhaustion. Undoubtedly many bulbs are weakened now owing to being improperly treated. Scores of plants, which are healthy with the exception of a few basal main leaves, are allowed to become dry too early; consequently the tubers gradually lose much strength in the autumn and start badly the following spring. Such plants should be fed regularly with weak doses of manure-water or other approved stimulant. When the Begonia leaves assume a yellow tint, stop all feeding and also gradually withhold clear water. Gloxinias and Gesneras: When all the flowers have faded and the leaves begin to droop, gradually withhold water, and only give one watering after all the leaves are removed. Retain the tubers in the soil in the pots until next spring, and keep them in a medium temperature, never nearer to the hot-water pipes than 2 feet. Cover the pots with mats; then the tubers will not dry-rot. AVON.

B AND C.—SUGGESTIONS FOR FORMAL BEDS FOR SPRING EFFECT.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Tomatoes.—The plants from which supplies are expected in the winter should be setting fruit freely, and will require careful attention to watering. Examine the pots several times daily, and water thoroughly as it becomes necessary. All side shoots should be removed as they appear, and when sufficient trusses have set, the top may be pinched out of each plant. Liquid manure should then be given, and the roots may be top-dressed with fine loam and artificial manure. Seeds can now be sown to produce plants for early spring fruiting. Sow thinly in pans of fine soil, and when the young plants are through the surface, the pans should be placed quite close to the roof glass in a well-ventilated pit. In order to keep the plants stocky, pot into small pots when large enough and avoid cold draughts during the winter.

Early Vines.—If ripe Grapes are desired in April, pot Vines should be selected at once and placed in an exposed position, preferably a south wall or in front of some forcing-house facing south. Let the Vines be cut back to the desired length at once, so that the wound may be dried up and a serious loss of sap avoided. These Vines should be started early in November. In the meantime the roots must not be allowed to become too dry.

Ripe Grapes.—Bunches of ripe Grapes should be frequently examined and all decaying berries removed. Ventilate the house freely and protect the bunches from scorching sun, especially black varieties, which soon lose their colour through exposure.

Plants Under Glass.

Mignonette.—Seeds may still be sown to produce plants for flowering in the spring. Five-inch pots should be used, and the soil may consist of rich loam, which should be mixed with lime rubble in place of sand. Let the soil be moderately dry and make it very firm. Sow the seeds thinly and place the pots in a cold pit, which must be protected from strong sun until germination takes place. When large enough, the seedlings should be thinned to four or five in each pot. As soon as good growth has been made, the plants may be removed to the shelf of a greenhouse, quite close to the roof glass.

Cinerarias for winter flowering should be removed from the cold pits to a well-ventilated greenhouse. Examine the plants and, if necessary, fumigate before their removal from the pits. Later plants in small pots should now be transferred to their flowering pots. Keep the pit close for a few days until the plants are re-established, after which air should be freely given. The most forward plants may be freely watered with weak liquid manure from the farmyard.

Lachenalias.—The bulbs of these charming plants should now be potted in well-crooked pots. The soil may consist of two parts rich loam, one part leaf-soil, and the remainder of cow-manure and rough sand or road grit. Six or seven bulbs can be placed in 5-inch pots and covered with half an inch of fine soil. A good watering should be given, and the pots may be placed on a bed of ashes in a shallow pit from which frost can be excluded in the winter. Very little water will be necessary during the winter until growth is well advanced, after which a liberal supply must be given.

The Flower Garden.

Autumn-Flowering Chrysanthemums.—These should now be at their best, and ought to receive careful attention with regard to supporting the flower-stems against rough wind or heavy rain. If one good stick is placed in the middle of each clump, the flower-stems may be secured separately to the same support; and if dry weather prevails, a good supply of water will be necessary.

Spring Bedding Plants.—The stock of plants should be examined with regard to numbers, and if there is any doubt about this matter, more plants can be pricked out from the seed-beds, so that, when the time for planting arrives, there may be no scarcity of plants. The plants in nursery beds should have the soil stirred between them frequently, in order to promote clean, healthy growth.

The Rock Garden.—The most important work in connection with the rock garden now is the transplanting of young seedlings or plants raised from cuttings. Small pots may be used for tender subjects requiring the protection of a frame during the winter, but those which are quite hardy may be planted in their permanent quarters as soon as possible. Cut back overgrown plants and keep the surroundings quite free from weeds.

The Hardy Fruit Garden.

Gathering Fruit.—This work should be done while the fruits are quite dry, especially if they are to be placed in the store-room for home use. Great care should be exercised in picking each individual fruit, taking care that none of them is bruised before they are placed in the fruit-room. Later varieties of Apples and Pears must be allowed to remain on the trees as long as possible, especially if they are in a sheltered position.

Root-Pruning.—In the case of overgrown trees which are unproductive year after year, root-pruning may be commenced at once. A trench should be taken out to the depth of 4 feet and 6 feet from the stem, so that the soil may be carefully worked back. All strong roots which are growing in a downward direction should be cut, also those which are without fibres and running too far from the tree. When this has been accomplished, the space should be carefully filled in with suitable soil and the roots replaced in the same manner as if planting a young tree. In the case of young trees which are growing too freely, it is better to lift them entirely and replant them, keeping the roots as near the surface as possible.

The Kitchen Garden.

Winter Salad.—Every available pit should be filled with Lettuce or other salad plants with as little delay as possible. If seeds were sown in August, there ought to be plenty of strong plants ready now, and it is better practice to plant both Lettuce and Endive in the pits now than to wait until they are in an advanced state and then lift them, which may be after they are injured by frost.

Parsley.—The principal bed of Parsley should be cut close to the ground, in order to promote the growth of dwarf green leaves, which will stand through the winter better than plants which are left uncut.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Carrots.—The storing of Carrots must now claim attention, particularly those growing on cold or wet soils. Experience has shown that, although the tops appear perfectly fresh, yet in wet seasons the Carrots split badly if allowed to remain in the ground after this date. Not only so, but they become so coarse that they are only fit for feeding cattle. If lifted now they will keep perfectly fresh stored in pits with a little soil thrown on the top of each layer. Where wire-worm has been present, the ground should receive a good dressing of gas-lime, after which it may be allowed to lie on the surface for a time before digging it in.

Beet may also be lifted and stored any time after this date, and as this is the most tender of all root crops, the greatest care must be taken in doing so. The tops had better be twisted off with the hands, as there is great danger from bleeding if a knife is used, especially if cut too near the crown.

Seakale.—Continue to keep the ground clear of weeds and decayed leaves, and run the hoe among the rows to encourage the formation of the crowns. However carefully they have been dressed before planting, flowering shoots will appear, which must be cut out at once.

The Flower Garden.

Dianthus Napoleon III.—Although the majority of the charming and beautiful Dianthi are not difficult to grow, yet this variety often causes great heart-burning. This season, however, it has

bloomed well and given great satisfaction. The chief essentials to success are good drainage, a light, porous soil, and sufficient moisture during summer. Where cuttings can be procured, they should be inserted now in the alpine frame, where they will root freely, and whatever losses may take place during the winter, these cuttings will provide next season's supply.

Viola gracilis.—This fine Grecian variety, with its deep violet flowers and compact habit, cannot fail to arrest attention in any collection. Its proper place, perhaps, is in a shady corner of the rockery where it will get a plentiful supply of moisture. It may also be used as a groundwork for some of the moisture-loving subtropical plants. It is easily increased by divisions; but where the supply is limited, cuttings may be taken now, which should make nice plants by the spring.

Sweet Peas.—From an exhibition point of view, Sweet Peas cannot be said to have been quite up to the standard usually seen in the North. Whether this was due to the cold weather we experienced in the late spring and early summer I cannot say; at all events, they remained more or less stunted all the season. To avoid disappointment next spring, it will be advisable to harvest as many of the seed-pods as can be secured. This to the average grower is a very small matter indeed, and will not entail much time or labour. Growers in the South may have been more fortunate; but in these uncertain times it will be as well to take precautions.

Plants Under Glass.

Perpetual-Flowering Carnations.—Where these have been grown in cold frames during the summer months, they had better be moved to their flowering quarters. Not but what they can stand any amount of cold; it is the dampness that is to be avoided, as this is certain to encourage attacks of rust, besides weakening the growths. As a precaution against green fly, the house had better be fumigated. The most forward plants will now be pushing up their flower-spikes, and may be given some artificial feeding.

Nerines.—These fine autumn-flowering bulbs must now receive attention, and although their culture is of the easiest description, they are not always seen at their best. Perhaps the too free use of the water-pot is in a great measure responsible for this. Plants that have been stored should now be brought out and placed on a shelf in a cool house, and on no account must water be given until the flower-spikes appear. If water is given before this, the result will be an abundant crop of leaves and very few flowers. The plants must not be repotted very often; it is surprising how long they will thrive in small pots.

Mignonette.—Another sowing should now be made to provide a succession to those sown last month. Sow one or two seeds in small pots and place on a shelf in the greenhouse or in a cold frame. If specimens are desired, thin to one plant and pot on as required. It will be well to remember that all blooms must be nipped out as they appear until the plant has grown to the desired height.

The Hardy Fruit Garden.

Morello Cherries.—Now that most of the fruit will have been gathered, the trees should be gone over and all unnecessary growths removed to enable next year's fruiting wood to be better exposed to the weather. Any trees that have been infested with insects should be syringed with some solution.

Melons.—Plants that are now swelling their fruits often show a tendency to flag; but with care in watering and judicious ventilation this can, to a certain extent, be obviated. Syringing the plants might almost be dispensed with, but continue to damp the walls and paths.

Midseason Vines.—When the Grapes have been gathered, the shoots should be half-pruned to enable the basal buds to be fully developed. Should red spider have become troublesome, this is a favourable opportunity to get rid of it. Fumigation with potassium sulphide is, perhaps, the most effective fumigant for this purpose. Remove the surface-dressing and fallen leaves, which will undoubtedly contain all manner of insects. Water should be given to the border if required, but avoid over-watering.

JOHN HIGHGATE.

THE GARDEN.

No. 2236.—VOL. LXXVIII.

SEPTEMBER 26, 1914.

NOTES OF THE WEEK.

To Our Readers.—Since the outbreak of war there has been a natural tendency to economise wherever possible. The result of this economy has naturally been to inflict considerable hardship on many sections of the community, and few industries have felt the pinch worse than those connected with the supply of plants and seeds for our gardens. For this reason we make a direct appeal to all our readers who can possibly afford it to refrain from cutting down their seed, bulb or plant orders to the irreducible minimum. Every order placed now means work for a thoroughly deserving class of men who, unless business can be kept going as usual, will certainly be without the means of earning their daily bread. At this time of strife the quiet and natural beauty so characteristic of the gardens of this country should provide a welcome solace to those whose minds are distracted by stories and scenes of war. Already many who have been stricken in war are returning home, and surely there is no better place for convalescence than a well-ordered garden. While sympathising fully with those who feel it necessary to economise in many directions, we would remind them that the expenditure for plants, seeds or bulbs is not a very large item of expense. To curtail it seriously would be to interfere with the employment of many workmen in the large houses, and would also lessen the pleasure which returning soldiers might otherwise find in the garden.

White Heather in September.

One of the best forms of White Heather flowering in our gardens just now is a variety of the common kind, and named *Calluna vulgaris alba Serlei*. It makes a dense bush from 18 inches to 2 feet high, and branches freely, so that it is quite a useful and strong plant. Its pure white flowers are produced in abundance, so that there is plenty of material for cutting at this season. It needs the same treatment as that afforded the hardy Heaths, viz., well-drained soil, free from lime, and moderately rich in humus or decayed vegetable matter.

A Beautiful Michaelmas Daisy.—Among the earlier-flowering Starworts or Asters there are few more beautiful than the variety *Lil Fardell*. This belongs to the *Novæ-Angliæ* section, and is a useful plant for filling large beds or for creating

bright patches of colour in the autumn border. It attains a height of about five feet, the large flowers being freely produced in clusters on erect stems. The colour is bright glowing rose, and in their early stages each has a prominent yellow disc, which forms a pleasing contrast to the outer florets.

A Charming Chinese Shrub.—In *Sophora viciifolia*, a native of Western China, we have a particularly graceful hardy shrub, and one that is as yet unknown in many gardens. It was in 1897 when this shrub was first introduced to Kew, but since that time seeds have been sent home by several collectors, so that there must be a good stock of it in various nurseries. The

FLOWERING SHOOTS OF *SOPHORA VICIIFOLIA*, A HARDY SHRUB FROM WESTERN CHINA.

illustration gives a good idea of the shape of the leaves, which are about two inches long, and also of the flowers, which are bluish white, each having a decided blue calyx. This *Sophora* is perfectly hardy, but likes a sunny position and well-drained soil that is not too heavy. Apart from these details, it needs no special treatment.

National Sweet Pea Society's Trials of Novelties.—The National Sweet Pea Society has decided to hold its trials of novelties as usual next year. Those who wish to send seeds of novelties for trial should send thirty of each variety to the secretary, Mr. H. D. Tigwell, Greenford, Middlesex, to reach him not later than October 10th. A fee of 2s. 6d. must

accompany each variety sent for trial. The seeds must be in a plain sealed packet, and this packet enclosed in another larger envelope. This outer packet must bear the raiser's name, the name or number of the variety, and its colour description.

Rhododendrons for the Panama Pacific International Exposition.—Messrs. R. Gill and Son of Falmouth inform us that they have secured the order to supply the Rhododendrons required for planting the grounds of the above exposition, to be held at San Francisco in 1915. Some idea of the magnitude of the order may be gleaned from the fact that over seven thousand plants are ordered, among

them 100 of the well-known variety *Cornubia*, these plants being 6 feet high and 5 feet through. All the plants are well budded, and look well and give great promise, so they ought to make a fine display.

A Grey-Leaved Plant for Autumn Effect.—At this season, when most of the outdoor flowers have had their beauty spoiled by the cold winds and rain, the quiet beauty of the foliage of some is more fully appreciated. One of the best grey-leaved plants is the *Lavender Cotton*, a low-growing shrub that rejoices in the awesome botanical name of *Santolina Chamæcyparissus*. For creating bold splashes of soft colour in front of the shrub border, or in almost any other situation, it is excellent. It will thrive in the poorest soil, but to keep it compact it is advisable to cut it back to within a few inches of the soil each spring. Beyond that it calls for little attention.

A White Dahlia for Bedding.—Although Dahlias are not favourites with everyone, there is no gain-saying the fact that they are useful for creating bright effects in the garden during the waning days of summer and well into the autumn, until frost puts a stop to their display. One of the best white varieties for filling large beds, or spacious gaps in the herbaceous border, is *Kaiserin Augusta Victoria*, a fairly old Dahlia that deserves to be better known. It is far from being an exhibitonary variety, but its erect habit and freedom of flowering put it in the front rank of those suitable for the garden. It grows about five feet high, and its erect double blossoms, borne well above the foliage, are as good a white as one could desire.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

National Rose Society and the War.—In reference to the donation of 50 guineas made to Queen Alexandra's Relief Fund, and published in our last issue, the following letter has been received by Mr. C. E. Shea, president of the society: "I have to acknowledge the receipt of your letter of the 9th inst. forwarding for submission to Queen Alexandra an open letter to Her Majesty's address, together with a cheque for 50 guineas, a contribution from the National Rose Society towards Queen Alexandra's Relief Fund. Both letter and cheque, as requested, I submitted to the Queen, and I write now by Her Majesty's command to thank you, and through you the Council of the National Rose Society, very sincerely for the handsome donation voted by your Council to be placed at Queen Alexandra's disposal. You will see from the official receipt which I enclose

flower for sale. I have come across it three or four times in my travels, but it was only last spring that I had the good fortune to get some two dozen seedlings from a friend. These have given a good account of themselves, having well filled a moderately sized bed, the plants attaining a height of from 3 feet to 4 feet. (Nicholson gives its height as 2 feet.) The spikes have measured from 6 inches to 15 inches in length. It is not so deliciously fragrant as the common Mignonette (*Reseda odorata*), but it is more beautiful in form, its finely cut foliage adding to its effectiveness. Set well back in a border of annuals, it will hold its own against all comers. The question, however, will be, Where can I get it?—CALEDONIA.

Magnolia Watsonii in Scotland.—It may interest many readers of THE GARDEN to learn that this beautiful and highly fragrant Japanese Magnolia is flowering in my garden for the second time this year. The blooms are nearly as large as they were during the months of June and July.—DAVID R. WILLIAMSON.

here with me the cobweb characteristic is even more marked, being denser in character and more hoary looking, although the stronger contrast against the red rosette instead of a green one may partially, although not, I think, wholly, account for it. The hummocky nature of the growth is well shown in the photograph. It is growing on a dwarf pillar or pier that finishes off, with others of like character, a small piece of paved garden from the lawn. The photograph shows a somewhat later stage of growth than Mr. Malby's, as it is in full flower, although most of the flowers are outside the plate. The pier is hollow, and is built round solid loam, so the plant on top has plenty of root-room. It has only been planted two years, and is increasing rapidly. The pieces at the sides were, when planted, single rosettes. Where not fully exposed to the sun's rays, the spider web is only a dot in the centre, and does not cover the whole rosette, thus confirming Mr. Malby. One point I would like to raise. My plants of *S. arachnoideum* are quite green, and I have never noticed the red tinge he refers to as being so conspicuous in their native habitats. Is it possible that the *Sempervivum* he saw was the variety *Laggeri*, sometimes called *rubrum*? —HERBERT E. MOLYNEUX, Southampton.

The Pyracantha and Birds.—On page 411 of THE GARDEN for August 15 last was an interesting note on "The Pyracantha as a Flowering Shrub," in which the writer refers principally to its adaptability for cultivation in the open garden on account of its attractiveness over a lengthened period of the season, both of flowering and fruiting. As a wall plant I can fully endorse the lengthened period of its attraction, and particularly in a season like that now drawing to a close, which seems to have been specially favourable in this part of the country for Thorns in general, the roadside hedges being thickly covered with dense masses of red berries of the common Hawthorn, providing, one would think, sufficient food for any number of wild birds for some time to come; but they seem to have a distinct preference for the Pyracantha. A large part of the front of my house is covered with a plant of *Cratægus Pyracantha Lelandii*, which I planted when it was about two feet high in 1901. It is now about twenty feet or thirty feet high and several feet wide. It would have grown much higher, but it has been kept down from encroaching on the guttering which runs round the house. In the early summer the thick masses of white flowers almost entirely covered the foliage from a distance of about twelve feet from the ground to the very top, and these have been succeeded by an equally thick crop of the orange red berries, which are now becoming rapidly thinned by hosts of birds, who begin their depredations very early in the morning and continue all day; so that though the crop is a heavy one, the beauty of the plant will soon be a thing of the past. I tried netting the plant one summer, but the birds got so entangled in the net as to cause much damage to the plant. At the back of the house is a good-sized standard Hawthorn tree which also carries every year a good crop of berries, but though this has its share of feathered visitors they are not so numerous as they are to the *Cratægus*. This would appear to be due to the bright colour and the crowded bunches giving much less trouble than those of the Hawthorn.—JOHN R. JACKSON, South Devon.

A BEAUTIFUL COBWEB HOUSELEEK, SEMPERVIVUM LAGGERI, IN A HAMPSHIRE GARDEN.

that Queen Alexandra has sent the cheque for 50 guineas to the Soldiers' and Sailors' Families Association, an association of which Her Majesty is president, and is deeply interested in the great work it is doing.—D. M. PROBYN, General, Comptroller to H.M. Queen Alexandra."

Double-Flowered Peach Fruiting.—In 1911 I wrote to you about a double-flowering Peach tree fruiting, and you answered saying you were not aware it did fruit, and that if it produced a fruit again you would like to see one. I herewith enclose you one. The tree is growing as a standard in a south-west aspect, and sheltered by larger trees from the north-west. It has not fruited since 1911 till now.—G. DUELL, The Grange Gardens, Kew Road, Kew. [The fruit sent by our correspondent was of medium size, fairly well ripened and of moderate quality.—Ed.]

The White Mignonette (*Reseda alba*).—This Mignonette is classed as a biennial, but succeeds admirably treated as a half-hardy annual. I wonder how it is that, so far as I can see, none of our seedsmen offer seed of this attractive

Disease in Early Planted Potatoes.—In a district in Hampshire noted for high-class Potato culture (Magnum Bonum, Clarke's Maincrop Kidney and other varieties being raised in it) many early plantations have very badly diseased tops at the present time (first week in September), whereas the late-planted ones are in a healthy condition. Of course, this may be regarded as quite a natural result, but the contrast is too great, as the time lapsing between the two plantings does not correspond. The tubers are not affected so far. The tops commenced to shrivel up early in August, and have in many places quite disappeared from general view. The haulm of the early planted Potatoes was weak from the first, whereas that of the late planted ones was strong and remains so.—B.

Sempervivum Laggeri.—Your correspondent's note on the Cobweb Houseleek or *Sempervivum arachnoideum* in your issue of August 29 last, page 437, is interesting, and I enclose a photograph of another member of the same family identical in all its parts, except that the whole plant is reddish in colour instead of green, and

Sweet Peas Diseased.—I see in THE GARDEN of August 22 an answer to a correspondent who is designated "An Old Subscriber," to the effect that his Sweet Peas are badly attacked by Thielavia basicola. I am engaged in research on the parasitism of this fungus, and at the moment am badly in need of some Sweet Pea material showing this disease. I think it possible that "An Old Subscriber" or some other of your readers might be so good as to supply me with what I want, and I should be very grateful if they would send entire plants to me at this address. If possible, I would prefer the name of the variety attached to the plant.—MAURICE A. BAILEY, *The John Innes Horticultural Institution, Merton, Surrey.*

Bottling Fruit.—I was greatly astonished to read, in the otherwise excellent Fruit Bottling leaflet of the Royal Horticultural Society, a recommendation to use bullocks' bladder to cover the bottles. Long ago (before Father Time, like our Government, "withdrew the gold" from my curls and only gave me a sprinkling of silver in place thereof) I had gladly discarded the troublesome, expensive bladders for the far more convenient, cheap and cleanly vegetable parchment covers sold in packets of assorted sizes by every stationer. Besides, oh! Royal Horticultural Society, how can some twenty or thirty country housewives obtain bladders in villages where the local butcher has probably only one or two to sell in a week?—ANNE AMATEUR.

Lectures on Carnations.—I find I have several dates vacant for lectures on "The Perpetual-flowering Carnation" to horticultural societies during the coming winter, and wondered if you would care to make this fact known in THE GARDEN, as undoubtedly many secretaries of societies are anxious to secure lecturers. Of course, I do not make any charge, as it is my mission to emphasise the fact that the Perpetual-flowering Carnation is perfectly hardy and flowers well out of doors; that it is not necessary to have a heated greenhouse, as it flowers quite well in a cold one; also to point out that it is not a flower for multi-millionaires only, as anyone can make a good start with a 1s. 6d. packet of seed. This, I imagine, would help to broaden the sphere of this flower.—MONTAGU C. ALLWOOD, *Wivelsfield Nursery, Hayward's Heath.*

Sweet Pea History.—I have lately been reading Mr. Charles H. Curtis' interesting paper on "A Hundred Years of Progress with Sweet Peas," read at the Conference at Shepherd's Bush last July. In the course of it he says "yet if we are to believe Phillips ('Flora Historica'), the Sweet Pea was very popular in 1824. He wrote at that date: 'The Sweet Pea is so universally admired and so easily cultivated that we now meet with it in every garden, from the palace of the monarch to the cottage of the peasant.'" From the above wording it would appear that the author of the paper is a little dubious about the exactitude of Phillips' statement. It may be of interest to lovers of the flower to know that I have before me a catalogue of the celebrated Thomas Davey of King's Road, Chelsea, dated 1823-24, in which among the hardy annuals six varieties of Sweet Peas are offered for sale, viz., Black, Painted Lady, Purple, Scarlet, White, and Winged. As the Tangier Pea is included under the heading "Sweet Peas," "Winged" might possibly refer to something we would not recognise as a Sweet Pea to-day. Even if it does,

this still leaves us with five varieties, a number more than sufficient to substantiate Phillips' statement. On turning up the article in the "Flora Historica" I was a little surprised to find that the practice of sowing in small pots in the autumn and wintering the young plants in frames was not altogether the modern evolution of the grower for exhibition, but that it was evidently often practised in 1824, when Phillips wrote his well-known work: "When sown in pots . . . October is a good time for this sowing, and when they are removed to the house or placed under frames . . ." Is there anything new under the sun?—JOSEPH JACOB.

When to Plant Tulips.—I feel considerable diffidence in questioning the advice as to the planting of Tulips given by your contributor Mr. John Dunn in your issue of the 29th ult., but it is contrary to authorities and to my own experience. He tells us "The bulbs of late-flowering Tulips should be planted as soon as they can be obtained, for, although it is not usual to plant bedding varieties before October or November, Darwin and Cottage varieties will give better results if planted a month before that time." Surely he has put "the cart before the horse"! Bedding Tulips, which are generally accepted as early ones, should be planted before the Darwin and Cottage varieties, as the object is to get them into flower in April, so as to make room for summer bedding plants. There is no need for this with the Darwin and Cottage varieties. Several times I had my Darwin and Cottage varieties attacked by "fire" when planted in September, and on my asking advice of one of the principal exhibitors of these glorious flowers, he told me I planted far too early, and he advised me to remember that our ancestors never planted Cottage Tulips (and Darwins probably sprang from them) before Lord Mayor's Day (November 9). I have followed his instructions the last three years, with the result that my Darwins have been spared the devastating visitation of "fire." Furthermore, I believe the Tulips grown at Wisley for the nomenclature trial last spring were not planted till mid-November, and they were so great a success as to be deemed worthy of praise by the Dutch experts who examined them. Mr. William Robinson in "The English Flower Garden" makes the general statement that Tulips may be planted from October to the middle of November, and the Rev. J. Jacob says in his instructive and delightful book on Tulips: "I endeavour to get all my best bulbs in the ground between, say, October 20 and November 15. One year I planted up to the week before Christmas, and I never had a better show than in the succeeding spring," and in his Summary he further says, "Plant early in November." Will Mr. Dunn kindly give us his reasons for his advising early planting?—OBSERVER, *Weybridge.*

FORTHCOMING EVENTS.

September 29 and 30.—Royal Horticultural Society's Show of British-grown Fruits, 1 p.m. to 7 p.m. Lecture at 3 p.m. by Mr. E. A. Bunyard on "The Literature of Pomology." Royal Horticultural Hall, Vincent Square, Westminster.

October 6.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1 p.m. to 7 p.m. Lecture at 3 p.m. by Mr. James Hudson, V.M.H., on "The Art of Informal Gardening." Royal Horticultural Hall, Vincent Square, Westminster.

SOME FALLACIES ABOUT VEGETABLE GROWING.

SINCE the war broke out early in August, and Professor Keeble and the Rev. W. Wilks, on behalf of the Royal Horticultural Society, issued a leaflet urging Fellows and others to sow and plant as many vegetable crops as possible, a good deal of useless and, in some instances, misleading advice has been given publicity, particularly in the columns of provincial newspapers. While recognising fully the desirability of increasing and husbanding our food supplies to the fullest extent, we also recognise the danger of this advice, given evidently by persons who have had little or no experience of actual cultivation, or who have acted without giving due thought to the difficulties encountered by the inexperienced amateur.

The most misleading statements have been those relating to waste ground, by which it is evident that the writers had in mind odd plots of waste building land in the vicinity of towns. Now, in eight cases out of ten these plots have been derelict for years, the dumping-place of all the household rubbish that cannot be legitimately disposed of in the dustbin, and the home of Docks, Thistles, Nettles and other coarse-growing weeds that are too well known to need mentioning. Yet in August we were advised to dig up such waste ground and sow it with, among other kinds, such roots as Onions, Carrots and Beetroots. The experienced gardener knows only too well that to sow seed of such crops in land of this character is to at once court failure; hence the mischievousness of the advice. We are glad to see that the Board of Agriculture, in Special Leaflet No. 1, recognise this danger, and class land for special vegetable cultivation under three heads, viz., A, cultivated land; B, good grassland broken up for spade cultivation; C, derelict land; and give advice accordingly. This leaflet we hope to publish in an early issue.

We are perfectly well aware that derelict land, such as we have described, can be rendered suitable for some kinds of crops, such as Potatoes and coarse Greens, within a few months of breaking it up, but even then it needs considerable labour and exposure to the elements. Where such land exists and is available for cultivation, it should be broken up as soon as possible to a depth of 2 feet, keeping the lower foot in its original stratum and working into the whole depth any manure, vegetable refuse, such as leaves, grass and anything else that will quickly decay, burnt garden refuse or earth, but not coal-ashes; and by the coasts Seaweed may be utilised. All deep-rooting weeds, such as Docks and Nettles, must be removed and burned, as it is impossible to destroy them by burying.

Land of this description should not be sown or planted until the spring, in the meantime keeping the top spit forked over as frequently as possible during comparatively dry periods of the winter. Even in spring, owing to the fact that weeds from seeds are certain to be plentiful, only quick and strong-growing crops, such as Potatoes and Greens, ought to be put in. Onions, Carrots, Beetroots, Parsnips and similar crops would scarcely find the soil to their liking, and, even if they did, would soon be overrun with weeds, unless the cultivator could give them almost daily attention.

ROSE-GROWING IN TOWN GARDENS.

IN a dry period such as has been experienced on more than one occasion during the present summer, the question of watering the Roses always arises. It is not advisable to give frequent applications of cold tap-water, and turning the hose right on to the roots of the plants is likely to do harm rather than good. Excessive watering undoubtedly causes the spread of mildew and undermines the health of the plants. On the other hand, dryness at the roots will cause them to wilt and become defoliated, so that in a drought we must choose the lesser evil. The bad effects of the hose are mitigated if a sprinkler is used, which sends the water upwards, allowing it to fall upon the beds in small drops which have become warmed by contact with the air. Constant hoeing conserves the moisture as long as possible, but there are times when it becomes essential to water artificially. In heavy soils, which are, of course, more retentive, the necessity is not nearly so great; but where the staple is of a lighter nature, it should be seen that the beds are completely moistened at least once a fortnight. When watering is done, it must be carried out effectually, and at least three gallons should be given to each square yard. Merely wetting the surface is of no use whatever, as water applied in this way evaporates almost at once without benefit to the roots. In this respect it is well to remember that summer showers are often so light that they fail to penetrate sufficiently to do good, and therefore it becomes necessary on occasions to water after rain.

Now is the time we begin to appreciate those of our plants which the catalogues describe as "good in autumn." The advantages of the kinds which bloom continuously are so apparent in the small garden that, if their merits were more fully known, surely no others would be cultivated in towns except by exhibitors. Inasmuch as freedom of flowering is possibly the most important attribute to the majority of growers, it would be of real advantage if some easy method could be adopted of classifying the different varieties in accordance with the approximate number of crops of bloom which they may be expected to give. Perhaps in time the National Rose Society will add to its good work by giving a lead in this direction in its Official List, which no doubt nurserymen would be glad to transfer to their catalogues. P. L. GODDARD.

[In the 1914 list the Society does indicate, after the descriptions of a few varieties, that they are "good in autumn," but a special list of the best sorts for autumn effect would undoubtedly be useful. We will shortly publish an article on the best.—ED.]

GIANT ASPHODELS.

(Continued from page 465.)

Planting Season.—The best period for planting Eremuri is September and October, though it may be extended into November in the case of light soils. Given a choice, I should unhesitatingly prefer September. In planting, keep the crowns 4 inches to 6 inches below the soil, where they will be safe from frost and comparatively so from risk. Some have recommended keeping the crowns well above the ground at planting-time. This is a mistake. Had they studied the annual method of root production in these plants and the way the crowns of the giants of the tribe

A WELL-FLOWERED EXAMPLE OF THE JAPANESE SNOWBALL TREE, VIBURNUM PLICATUM.

incline to the surface naturally, they would not have done so. A point of importance in replanting is the brittleness of the roots, which break at the slightest touch. E. Bungei is one of the greatest sinners in this respect; hence much care is needed in dealing with it. In the transplanting of established garden clumps, a hole having a diameter of 3 feet or more, 6 inches deep, should be opened, so that the roots may take their natural lateral spread. For the first winter a protection of Bracken, short litter, or ashes and fibre should be given the crowns. In some soils slugs attack the crowns, but the danger of these may be reduced by placing boards, slates, or damp sacks with a little bran as a bait beneath. In this way they may be trapped in large numbers.

Propagation and Cultivation.—The most prolific source of increase is by means of seeds, which in a good season and with hand pollination are produced in abundance. Seeds are best sown within two months of harvesting and preferably in a cold frame, where they may remain for at least two seasons without disturbance. After this they may be transplanted to specially prepared beds for a further term of three years, when more room will be required. The seedlings should be transplanted almost with the maturing of their leaves. Such as E. Bungei divide naturally and easily; others, as E. robustus, with huge cone-like crowns, give offsets or split up more slowly. Apart from what has been said as to culture, the only item of importance is to see that the

plants do not suffer in the spring from extreme drought, should this occur. Instances have come to my notice where this has happened during the present year, the result being a partial blindness of the upper portion of the flower-spike. At such times all would be benefited by thorough watering and by occasional doses of liquid manure, particularly for the more robust-habited kinds.

Species and Varieties.—The former are native of Central and Southern Asia, but especially from Persia, Turkestan, the Himalayas, and even as far north as Siberia. The latter owe their origin to insect or wind agency and to the hybridist. Already the latter has been responsible for several fine additions, and doubtless the number of beautiful forms will be augmented in the near future. The flowering season is June and July, and doubtless this also will be extended as the work of cross-breeding goes on. The following are the principal kinds.

Eremurus Bungei.—Flowers clear citron yellow on spikes 4 feet to 8 feet high, depending on the strength of the crown. Pallidus and superbus are distinct varieties of this good and practically indispensable kind. June and July. Persia.

E. himalaicus.—The flowers are pure white, densely arranged on spikes that in the established examples reach to 8 feet high. A grand plant for grouping near dark-leaved evergreens. June. Himalaya.

E. him-rob.—A fine hybrid between E. himalaicus and E. robustus. The flowers are of the latter type and of a silvery rose. A really splendid plant.

E. Olgæ.—A July-flowering species from Turkestan. In habit the plant approximates to E. Bungei, the giant spikes of white red-tinted flowers rearing themselves to 8 feet high.

E. robustus.—This and E. r. elwesianus are the giants of the race, giants in stature and vigour above ground and below; hence they should be catered for accordingly. Their handsome spikes of rosy pink flowers may reach anything up to 10 feet or 11 feet high, when they are noble indeed. Of the magnificent effect of this type the illustration on page 465 of last week's issue from a photograph taken in Messrs. Wallace's Colchester Nurseries, will give an excellent idea. The habit of the plant is also well shown in the figure.

E. Shelford.—A glorious hybrid of tawny yellow and reddish bronze, the combination affording a unique picture in the sunlight.

E. Sir Michael.—A magnificent hybrid of the Shelford type, the predominating colour buff yellow. These are July-flowering, and the finest hybrids of the race.

E. Tubergenii is a hybrid between *E. Bungei* and *E. himalaicus*, intermediate between the parents in habit, and having tall spires of pale yellow flowers.

E. Warei.—A hybrid of splendid proportions and unique colouring. The flowers are reddish bronze, and provide a brilliant effect in the sunlight. It is one of the indispensables. E. H. JENKINS.

A HEDGE OF FRAGRANCE.

IN many gardens it is desirable to have a low, naturally grown hedge to form a well-defined boundary between two sections, and during late years many different kinds of shrubs have been utilised for this purpose. Where the soil is of a rather porous, and therefore warm character, there is nothing better than the common Rosemary, a shrub that is not nearly so slow growing as many suppose. Owing to its liability to injury from very severe frosts and cutting east and north-east winds, one would not recommend it for very cold localities or exposed positions, but there are hundreds of gardens where it might be planted as a hedge. If variety were needed, the common pink China or Monthly Rose could be mixed with it, in the proportion of about one Rose bush to every three of Rosemary. The grey under surface of the leaves of the latter blends delightfully with the colour of the Roses, and a hedge of this description would be interesting and pleasing at all seasons of the year. It ought not to be planted, however, where a close-clipped hedge is desired, as neither Roses nor Rosemary would submit to such restrictions for long. But both can be kept well within bounds by an annual or bi-annual shortening back with knife or secateurs of those shoots that encroach too far on the space desired for the pathway or for other plants. Rosemary bushes about one foot high can be purchased at a reasonable price, and may be planted in October, November or in February. To form a hedge they ought not to be set more than a foot or fifteen inches apart, and the soil should be well and deeply dug for their reception. Heavy manuring is neither necessary nor desirable. G. D.

NOTES ON VIBURNUMS.

THE Wayfaring Tree is in full bloom in May, and its umbel-like clusters of white flowers may be seen from afar. It is one of the most beautiful of our native shrubs, and grows freely in almost any soil, but especially on the hillsides overlying chalk. Not that it occurs in large stretches, for it is usual to see it scattered here and there on the outskirts of

the woodland or as a roadside shrub, for it is common in our hedgerows. To the botanist it is known as *Viburnum lantana*, but to country folk it will always be known as the Wayfaring Tree. Later on the flowers are followed by black, flattened fruits less than half an inch in length, and familiar objects of our hedgerows.

The Guelder Rose is companion to the Wayfaring Tree, but it is a few weeks later in coming into bloom. The white flowers are borne in globose heads, and for this reason it is often aptly called the Snowball Tree. But it has many other names, such as Dog Rowan Tree, Dog Elder, Marsh or Water Elder, and Cranberry Tree; while to the botanist it is *Viburnum Opulus*. The fruits are red and globose, also familiar objects of our countryside. In the garden Guelder Rose (*V. Opulus sterile*) nearly the whole head of bloom consists of sterile flowers. It is a very hand-

SOME GOOD AUTUMN-FLOWERING SHRUBS.

DURING the month of August many owners of gardens spend more time in them than at any other period of the year, yet too often the beauty of many of the plants has long since departed.

This is particularly noticeable among flowering shrubs, mainly owing to the fact that the majority, which are hardy, bloom during the early months of the year. Yet there is a goodly host which flower during August, and which might be planted much more extensively than they are at present. One of the most beautiful of these is *Buddleia variabilis*, introduced from China some twelve or fifteen years ago. Several varieties of it are obtainable, *veitchiana* being one of the best.

A BED OF THE AUSTRALIAN DAISY BUSH, *OLEARIA HAASTII*. THIS IS A GOOD AUTUMN-FLOWERING SHRUB.

some shrub, with perfect balls of snow white flowers.

The Japanese Snowball Tree (*V. plicatum*) shown in the illustration on the opposite page has clusters of white flowers resembling those of the Guelder Rose. May is its month for flowering, and there are now many gardens all the more beautiful owing to its presence. It is easily one of the six most beautiful shrubs for English gardens.

Notes on *Viburnums* would be incomplete without some reference to *Laurustinus* (*V. Tinus*), the fragrant evergreen which flowers from December onwards and may be seen in almost every garden in the country. All of the *Viburnums* referred to are quite hardy and of the easiest culture. They may be increased by layering the basal shoots, preferably in autumn, and from summer cuttings, while they thrive in almost any soil. All, except the *Laurustinus*, can be successfully planted in autumn or early spring; the *Laurustinus* in March. C. O.

It has long, semi-pendulous spikes of lilac-coloured flowers that are much beloved by the bees. The Tamarisks are a fairly large family, but the best is *Tamarix pentandra*, known to most nurserymen as *æstivalis* or *Pallasii rosea*. It has pale green feathery shoots, each of which forms a large, nodding, plume-like head of rose pink flowers. Of *Ceanothuses* we must not omit *Gloire de Versailles* (bright Cambridge blue) and *Ceres* (pale rose lilac). If cut down severely each winter, they make compact bushes about two feet high. In *Spiræas* *lindleyana* and *Aitchisonii* we have two tall shrubs with much-divided foliage and large plumes of creamy white flowers; while of dwarf kinds room must be made for *japonica* Anthony Waterer, crimson; *j. Bumalda*, rose pink; and *j. alba*. These, if pruned nearly to the ground each winter, make neat tufts of flowers not more than 18 inches high, and are excellent for lawn beds or the front of the shrubbery. The double-flowered pink Bramble or *Rubus*

is excellent for an open spot in the woodland, especially if allowed to ramble over some old tree stumps. The double white one is not so good. Although not strictly a shrub, the Californian Tree Poppy, *Romneya Coulteri*, is often classed as such, and is well worth giving the warm spot that is necessary to its well-being. At Kew, Aldenham House and a few other places they have a newer species, named *trichocalyx*. It has large, Poppy-like, silky white flowers, similar to those of *Coulteri*, but produces them more freely and makes a better bush. *Hydrangea arborescens grandiflora* is a good and perfectly hardy shrub with large heads of creamy white flowers, and *Hypericum Henryi* is a St. John's Wort 3 feet or more high, which in August is covered with large golden blossoms. It will thrive equally well in sun or shade. The Spanish Broom, *Spartium junceum*, with its green, Rush-like stems covered with brilliant yellow flowers, must not be omitted; it does well in poor soil. A good companion to it is the Mount Etna Broom, *Cytisus ætnensis*, which grows quickly and makes a small, pendulous tree, covered in August with bright yellow flowers. A fine Clematis of shrubby habit that comes from the Caucasus is *C. pseudo-Flammula*. It makes quite a thick bush, nearly six feet high, and in August is covered with large trusses of small, creamy white flowers which are very fragrant. *Olearia Haastii*, with small white flowers, is a slow-growing evergreen, and ought to be planted in a bed or to the front of the shrubbery. Those who appreciate uncommon shrubs should plant *Castanopsis chrysophylla*. It has medium-sized evergreen leaves, similar to those of the Evergreen Oak, and has small feathery tufts of creamy yellow flowers in August. The fruit that results from these does not mature until the following year, when it has a spiny coat similar to that of the Horse Chestnut. This *Castanopsis* makes a symmetrical shrub some 10 feet or more high, and is attractive as an evergreen. Another little-known shrub that flowers at this season is *Eucryphia pinnatifolia*, native of Chili, but, nevertheless, a hardy subject.

Now that the planting season is approaching, those who appreciate flowers in autumn should remember these shrubs. Most of those named are easily cultivated, but the Brooms should be obtained as small plants in pots, otherwise they suffer seriously in transplanting. In common with all other kinds of vegetation, shrubs appreciate well-cultivated soil, and this is work that will be particularly suitable during the coming weeks. Where possible, the land intended for shrubs should be broken up to a depth of 2 feet, and, if poor, some well-decayed manure thoroughly mixed with the whole.

H

EARLY FLOWERING CHRYSANTHEMUMS FOR BEDDING.

IT is now about twenty years since the early flowering outdoor Chrysanthemums began to show such marked superiority over those raised in earlier days, and during the past two decades they have enjoyed a triumphal progress in popular esteem. In the earlier days we were almost entirely dependent on Continental introductions, and no one did more to improve this hardier race of plants

a constitution that came through the severest winter with little or no harm to plants left outdoors throughout the whole of that season.

Plants of this kind were, therefore, considered to be ideal for the outdoor garden, and I question whether there is any better type of plant in cultivation to-day. Mme. Marie Massé and its sports are plants that do not take kindly to disbudding. They never look better than when grown in a natural manner, without disbudding. As a result of the introduction of this fine sort, growers in this country quickly found out how easy it was to save seed of this variety and its sports; and as pollen was so easily obtainable, British growers

made many crosses, and for some years afterwards it was an easy matter to trace the parentage of the newer introductions back to the excellent family to which reference has been made.

In later years English growers have largely superseded our Continental rivals as raisers of the outdoor Chrysanthemum, and many very beautiful sorts have been distributed that are highly prized to-day. The long run of British successes has been broken in a measure by M. Nonin, who has succeeded in introducing to this country a number of very charming sorts that are a complete break away from any of those raised by others. For a year or two this French raiser has added to our already long list sorts that are now in commerce and much valued by growers generally. A noteworthy example of this raiser's skill that I saw last year was a large bed planted with a beautiful soft pink variety named *Normandie*. It is a delightful acquisition. When it was first distributed I remember seeing a beautiful series of plants in a Midland garden, and I was so impressed with its beauty that I obtained permission to take back a bunch of flowers to London, where it was submitted to the judgment of the floral committee of the National Chrysanthemum Society, which body awarded a first-class certificate quite unanimously.

For creating bold masses of colour in the garden during the autumn months there is no other subject that possesses

such a wealth of glorious colours as the early flowering outdoor Chrysanthemum. The colours are so rich and varied, and the warmer tones now so largely preponderate, that the old charge made by prejudiced individuals that this was a dull and dowdy subject, chiefly represented by magenta and kindred tones of colour, no longer holds good. Bright and cheering in the dull days, they are indeed glorious in the light of the autumn sun, and the landscape lit up with bold masses of this subject is well worth studying to achieve. For smaller gardens, especially those of amateurs in the suburbs of the metropolis and large towns, they are invaluable, for, as soon as the glory of the summer garden

than the late M. Simon Delaux, who sent to this country a large number of very beautiful sorts. With the advent of Mme. Marie Massé in 1894 the character of these plants was vastly improved, for not only did this variety embody all that was needed in an outdoor Chrysanthemum, but in the years immediately subsequent to its introduction quite a number of sports in many diverse tones of colour were fixed and later distributed, so that in a comparatively short time there was available for enthusiastic growers of these plants quite a large number of sorts of various colours. The value of this variety and its sports was apparent to all, for not only were the plants extremely bushy and free-flowering, but they possessed

EARLY FLOWERING CHRYSANTHEMUMS IN A SMALL GARDEN.

has departed, the early flowering Chrysanthemums are ready to continue the floriferous display.

Either large or small beds of one variety make a very pretty floral picture, and planted in groups or masses of various sizes at intervals in the hardy border they are most attractive. Individual plants of the more bushy kinds here and there in the outdoor border is a method of planting that has much to commend it, but due regard for the respective colours in association should always be respected. One of the finest beds of early flowering Chrysanthemums I have seen was a combination of the free-flowering Japanese kinds, with a few plants of severely disbudded varieties interspersed here and there as a contrast. The edging to this large bed was composed of

THE JAPANESE WIND- FLOWERS.

IN the waning days of autumn, when the morning and evening mists have enshrouded the flowers of the outdoor garden and, in too many instances, marred their beauty, we appreciate those that come out of the ordeal unscathed. Among the most beautiful of these are the Japanese Windflowers or Anemones, tall yet graceful flowers, quite unlike the dainty little native species that bespangles the greensward of our coppices in the gusty days of spring. These Japanese Anemones, by their very stature and bearing, are admirably adapted

picture of sublime beauty with these and autumn foliage.

Fortunately, the cultivation of the Japanese Anemones does not present any great difficulties. What they do appreciate is deeply cultivated and well-manured soil, and that with a good proportion of clay in it. One is often asked to name plants that will thrive in clay soil, and the Japanese Windflower is one of the best. As the roots are long and thick, with but few fibres, transplanting is not advisable more often than is absolutely necessary; indeed, a good rule to follow is to disturb the plants as little as possible. In forming new beds or groups in borders, the planting may be done in late autumn or early spring, and

A BEAUTIFUL EFFECT CREATED BY PLANTING JAPANESE ANEMONES BY THE WATER-SIDE.

some of the dwarf-growing, miniature-flowered Pompon sorts.

The outdoor Chrysanthemums succeed better when planted in not over-rich soil. A too generous application of manure to quarters intended for these plants invariably promotes growth of a too luxuriant kind, which results in the plants making unduly tall growth and delay in the period of flowering. Plants should be well hardened off preparatory to planting outdoors, and the planting should be done during the first three weeks in May, varying the date of planting according to the position, exposed or otherwise. In a later contribution I shall be pleased to give selections for various purposes.

Highgate, N.

D. B. CRANE.

for grouping in the herbaceous border, in large lawn beds, the edges of shrubberies, or by the side of a pond or lake. They are never seen to better advantage, particularly the varieties with white blossoms, than when massed, as in the accompanying illustration, with a background of dark green foliaged trees, these serving to accentuate the glistening purity of the daintily poised blossoms. When to the trees water is added, in which the flowers are reflected with a shimmer of light and shade, we begin to realise how indispensable these hardy plants are in the garden at this season. Nor must we overlook their usefulness for cutting. It is almost impossible to arrange them inartistically, their long stems and light, graceful flowers enabling the veriest tyro to create a

pieces of root with as many fibres as possible should be given preference to those of a less fibrous character.

Contrary to a widespread belief, the original species has rose-coloured flowers with large, bold foliage, and a very useful plant it is. A variety named Honorine Joubert has pure white flowers and is still one of the best for general purposes. Others with white blossoms are Whirlwind, very large and semi-double; and sylvestris, smaller and earlier, with dwarfer habit. A larger form of this is known as grandiflora. There are several beautiful varieties with pink or rose coloured flowers, notably Queen Charlotte, very large, rosea, semi-double; Autumn Queen, crispifolia elegans and Lady Ardilaun.

TROJAN

GARDENING FOR BEGINNERS.

A USEFUL FRUIT GATHERER.

NOW that Apples and Pears are being gathered for storing during the winter, I think perhaps the following particulars of a home-made gatherer may be useful. Too often one finds those fruits that are unreachable left on the tree to spoil, or else knocked or shaken down and so ruined for keeping purposes. To gather fruit which is not reachable from the ground or by ladder, use a tin tied to a stick. For the stick get a stout Bamboo rod from 3 feet to 13 feet in length. Bore or burn a hole through the rod at or near the top. Punch some holes in the side of the can. Fill the can with wood and then holes can be made with a fair-sized French wire nail. Cut out several V's at the top of the can and turn down the edge of the can inside two-thirds of the way round. The spaces where the V's are catch and cut through the stalks of the fruit. Tie the can to the Bamboo rod so firmly that when the rod is twisted round, the tin goes with it. Place a little hay at the bottom of the tin. With a little care all the fruit can be gathered off a tree without any bruising whatever. I find the most effective tin is that which has contained "Frame Food," 3s. 9d. size. Its dimensions are: Height, top to bottom, 8 inches; width, side to side, 6 inches; depth, front to back, nearly 4 inches. A. W. W. P.

TAKING TENDER PLANTS UNDER GLASS.

WHERE glass accommodation is limited—and in the majority of small gardens it consists of but a single greenhouse—the question of the wintering of tender subjects is an important item at this season of the year. In order to provide room for the development of different plants which occupy only a small space in the winter, but a much larger space when they commence to grow, all the occupants of the greenhouse that can be so treated are stood outside during the summer months. With the approach of autumn and the possibility of frosts that may do them some damage, arrangements must be made to remove under cover the different plants it is intended to keep. When this is done, the greenhouse is sure to be filled to its utmost capacity; hence it should, if possible, be thoroughly cleaned while there is still room to move the plants about.

The house being thus put in order and any subjects that are not considered worth keeping being dispensed with, all is ready for a change in the weather, which may come on suddenly. It is not advisable to wait too long for this, as it is much better to take the plants under cover in a quiet manner than to rush them in when severe frost threatens. Plants that have been stood out of doors for some time should each be carefully examined for slugs or any other pests which are apt to collect on the bottoms of the pots and in any place that they can find shelter. When any that are found have been destroyed, the surface of the soil may be cleaned over with a label or thin piece of wood, and the pots thoroughly washed. If stood on a clean surface where they will not be splashed by heavy rains, all will be ready to take them into the greenhouse at short notice.

In doing this, though every inch of space may be a consideration, yet it is a mistaken policy to pack the plants too closely together, for under these conditions many will lose their leaves and be practically spoilt. A certain amount of forethought must be brought to bear on this, for some subjects, such as Fuchsias, which lose their leaves, and Lantanas, which also go partially to rest, may be stood so that the pots touch one another, whereas Indian Azaleas and other plants that are

A SIMPLE, HOME-MADE FRUIT GATHERER.
1, Back of tin; 2, front of tin; 3, tin tied tightly to Bamboo cane (No. 4).

strictly evergreen in character must have space for the air to circulate, otherwise they will quickly suffer.

Another point worthy of consideration is that insect pests, such as aphides or green fly and thrips, are apt to make considerable headway on plants out of doors towards the end of the summer, so that a very good plan is to fumigate or vaporise the house as soon as the plants are safely gathered therein.

It is quite possible that after a frost or two the weather may change, in which case it should be borne in mind that, the plants having been exposed to the outside air for so long, a close and stuffy atmosphere will cause many of the leaves to drop. Such being the case, plenty of air should be given on the greenhouse, not only during the day, but also at night when there is no risk of

frost. With this treatment the tissues of the plants are hardened, and they are better able to resist a long and trying frost during the winter.

The watering of the different plants from now onwards should, if possible, be done in the morning instead of the evening, which is the most suitable time during the summer months. At that period, if watering is done in the evening, it allows ample time for the roots to absorb the moisture, while during late autumn and winter it leads to a saturated atmosphere at night, which is detrimental to the health of the plants. During the summer, therefore, the best time to water is, naturally, in the evening.

Apart from the different plants which are established in pots, the greenhouse is often employed for the wintering of the summer bedding plants. Cuttings of Pelargoniums, Marguerites, Lantanas, Heliotrope, Fuchsias, &c., should be rooted before this, and all they require is a good light position in the greenhouse. On the other hand, any old plants that have done duty during the summer should be lifted, any straggling roots shortened back, and the tops treated in a similar manner. They must then be put into pots as small as the roots can be conveniently placed, as they winter better in comparatively small pots than in very large ones. While they need to be moderately watered till the roots take possession of the new soil, which will be soon, less water will be required in the winter. The removal of decaying leaves is a very important item, especially during the autumn and winter, as at those seasons the decay soon spreads to even healthy foliage, while in the summer it detracts greatly from the appearance of the greenhouse. H. P.

BEDDING-OUT PLANTS AND CUTTINGS.

EVEN where every convenience for the lifted plants and cuttings exists, there is a great deal of skill required in order to preserve them from injury during the winter months. Much more skill is needed where such conveniences do not exist.

The Cuttings.—The best rooted specimens do not possess many roots at the end of September, and those that are badly rooted then do not produce many more roots before the early part of the following spring. Now, it is obvious that such cuttings, especially if they are of a succulent nature, must be carefully treated as regards watering and ventilation. There is no better position for them than on a shelf in a greenhouse. Thorough drainage is ensured, and air can circulate among the pots, boxes and foliage very freely. Before placing the cuttings in their winter quarters, carefully examine them, and arrange those well rooted together and those indifferently rooted together, respectively. Then the cultivator can give water with more advantage and benefit to the cuttings than if all were mixed.

Lifted Plants.—Thousands of old plants are lifted and potted from the beds. These should not be potted in a large quantity of soil for wintering successfully. If there is enough in each pot to keep the plant steady, it will suffice. Many leaves will shrivel, but young ones will take their place next spring.

AVON.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Late Grapes are now colouring fast, and great care should be exercised with regard to ventilation and watering. Air may be freely admitted during the day while the weather is favourable, and the ventilators should be left slightly open at night, so that by the aid of a little fire-heat a light, buoyant atmosphere may be maintained.

Strawberry Plants for Early Forcing.—The pots are now filled with healthy roots, and will require some stimulant to keep them from becoming stunted. Manure-water from the farmyard answers the purpose well, but must always be applied in a weak state. Syringe the foliage daily, and if mildew makes its appearance, means must be adopted at once to clear the plants of this troublesome pest.

Plants Under Glass.

Begonia Gloire de Lorraine.—The earliest plants will now be well advanced, and should not be subjected to more than an intermediate temperature, or the constitution of the plants will suffer in consequence. A number of neat sticks should be placed in each pot and the shoots secured as it becomes necessary. A little stimulant may now be provided to keep the plants growing freely, and for this purpose Clay's Fertilizer will be found a safe manure, providing it is applied in moderation. Soot may also be applied with good results.

Roses in Pots.—The stock of pot Roses should now be examined and preparation made for potting. September is the best month for this purpose, as, after potting, the plants will produce a number of fresh roots before the foliage drops. The soil may consist of good turfy loam, with a small quantity of decayed cow-manure and sufficient rough sand to keep the compost open. Fine lime rubble may also be applied if the soil is heavy.

Chrysanthemums.—The most forward of the large-flowering kinds must be placed under cover as soon as the buds begin to show colour. A well-ventilated structure should be chosen for this purpose, and the buds must not be too far from the glass. In cases where the buds are too early, a north house may be the best place for them, but they must never be deprived of light. Stimulants of some kind should be carefully applied, but never of sufficient strength to injure the young roots.

Schizanthuses.—The plants intended for early spring flowering should be ready for potting into 4-inch pots. The soil may consist of good turfy loam and leaf-soil in equal parts, with sufficient sharp sand to keep it from becoming sour. A clean cold frame is the most suitable place for them during the autumn, but they must be removed to a well-ventilated greenhouse before the winter, and should be grown quite close to the roof glass in order to keep them stocky.

The Flower Garden.

Antirrhinums.—If good, stocky plants are required to put out in April, the present is a suitable time to sow the seeds. Sow thinly in boxes or pans, and prick out the seedlings as soon as large enough. Shallow boxes may be used for the purpose, and the plants should be allowed the protection of a cold frame in the winter. Cuttings may also be inserted now with a view to increasing any particular variety.

The Propagation of Violas, *Calceolarias*, *Veronica Andersonii* variegata and *Pentstemons* should be accomplished as soon as possible. The soil may consist of loam and leaf-soil in equal parts, with a good quantity of sand, and should be placed within 15 inches of the roof glass in a cold pit. Lavender and Rosemary cuttings may also be inserted now. The cuttings ought to be removed from the parent plant with a good heel, and made perfectly firm in sandy soil. By the month of April the plants should be ready to put out.

The Hardy Fruit Garden.

Strawberries.—No time should be lost in making the necessary new plantations of Strawberries.

This work may have been delayed in consequence of dry weather, but should now be pushed forward so that the plants may become established before the winter. If the ground has been prepared, the plants may be put out in rows 2½ feet apart, but careful watering will be necessary before their removal from the pots, and frequent applications of clear water should be applied after they are placed in position, for if once the small ball of soil is allowed to become dry, the plants may just as well be destroyed.

The Kitchen Garden.

Spinach.—The soil between the rows of Winter Spinach must be frequently hoed, and if the plants are too numerous, they may be thinned to 4 inches apart, as they will stand the winter better than if left unthinned. Frequent light dustings of soot may be applied with advantage during showery weather.

Lettuce.—Late-planted Lettuce can be treated in the same way, but at least 9 inches should be allowed from plant to plant in the rows. A sowing of Brown Cos, Hardy White Cos and Maximum may be made on a sheltered border for planting out in spring, and to make quite certain, another sowing should be made early in October in a cold frame.

Leeks.—These plants are gross feeders, and ought to receive frequent waterings of liquid manure from the farmyard. The soil ought afterwards to be deeply hoed, in order to kill small weeds and promote quick growth.

Autumn-Sown Onions.—As soon as the young plants are well through the ground, the Dutch hoe should be frequently used among them. Keep the rows quite free from weeds, and do all that is possible to promote clean, stocky growth.

Potatoes.—As soon as the tubers are sufficiently ripe for lifting, this work should be taken in hand, as, if left in the ground too long, some of the best tubers are almost sure to become affected by disease.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Late Peas.—Every encouragement should be given to the late Peas to fill the pods. If weeds have been allowed to grow among the plants, these must be cleared away, and if the growths appear too numerous, it would be advisable to thin these out, if it can be done without injury to the others. The Peas can be used when quite small, so that no pods should be thrown away because they do not appear to be well filled.

French Beans.—The same remarks apply to these Beans, particularly plants grown in frames. Pinch any that are becoming too tall, and do not hesitate to draw out a plant where they appear to be crowded; indeed, every care should be taken to prolong the season of supply.

Celery.—The main crop will now require earthing again, and it is more than ever necessary that this work should be performed when the soil is tolerably dry. Should the soil be of a heavy nature, it must be powdered down as fine as possible, and, as in former earthings, the greatest care must be taken not to allow the soil to reach the centre of the plant. In the North there is not much likelihood of a shortage of moisture at this season; still, if there is any chance of the roots being dry, give them a good soaking.

The Flower Garden.

Wall Climbers.—In the majority of cases these will now have completed their growth, and if time permits they should have the old wood cut out. This work must be very carefully done, otherwise much damage will result from tearing off the foliage of the young growths. Next season's flowering shoots should be loosely tied up, so that they may be thoroughly matured before severe weather sets in.

Planting Violets.—If the frames were prepared as already advised, the planting should be proceeded with at once. On the whole the season has been

favourable to their growth, and with care in lifting everything points to having a good display. In a great many cases it is indifferent lifting that accounts for the number of failures recorded. If possible, choose a showery day for the work, and keep the ball of soil round the roots perfectly intact. When the work is finished, the foliage should just be clear of the glass. Give the plants a good soaking of water to settle the soil about the roots, and if the weather is bright, shade for a few days afterwards, giving them abundance of air.

Dahlias.—These will now be giving a grand display, and, like all other robust-growing border plants, will in many cases require additional supports. Indeed, with a little extra attention in this way, these plants should give a fine display for some time yet.

Rose Cuttings.—It is always advisable to have a good stock of young climbing Roses, particularly of the *Hiawatha* and *Lady Gay* type, and as the majority of these root freely from cuttings, a good batch should now be secured. These will be found extremely useful for filling up blanks on the arches and pergolas, and clothing some old tree stumps. Select young, well-ripened shoots with a heel of the old wood. Plant them in nursery lines in ordinary garden soil which has been previously made moderately firm.

The Rock Garden.—This will now need careful attention, removing weeds and all decayed foliage. Besides ordinary rock plants, there are numerous bulbs that may be planted now, and in doing so endeavour to plant in fairly large groups, which will enhance the spring effect. Such bulbs as *Chionodoxas*, *Scillas*, *Muscari* and quite a number of the *Anemones* will now be at hand, and should be planted at once.

Plants Under Glass.

Ferns.—Where *Adiantums* and other stove Ferns are required for furnishing in the autumn, a number of the plants should be removed to a cool and airy house, where they can be gradually hardened off. The remaining plants will be greatly benefited by a little more room.

Early Flowering Tulips.—To have a supply of these for Christmas, no time should be lost in potting up the bulbs. Do not attempt to force them until they have made 2 inches or 3 inches of growth and the roots appear at the bottom of the pots.

The Hardy Fruit Garden.

Apples.—Preparations should be made for the gathering and storing of the earlier varieties of Apples, and this must not be done indiscriminately. Very often blackbirds will give warning that a certain variety is ripe by their too close attention to them, and if the fruits are not secured in time the birds will account for a good many of the best fruits. There is perhaps no better place in which to store Apples than an old thatched building with earthen floors, where the temperature fluctuates very little.

Pears.—The gathering and storing of Pears must be done very carefully, and where there is no danger of them being blown down by the wind, they should be allowed to hang as long as possible. In storing, it will be as well to grade the fruits, and all small and imperfect fruits may be stored together for culinary purposes. It will be necessary to look over them every day, as, no matter how carefully they have been gathered, some are sure to get bruised, and this sets up decay with remarkable rapidity.

Fruit Under Glass.

Orchard-House.—Any trees which require repotting should be seen to at once or, in the case of late-fruiting sorts, some time before the foliage begins to fall. But whether the trees require repotting or not, the drainage in each case must be carefully examined.

Cucumbers.—To ensure a supply during the winter months, a sowing should be made now. This batch had better be grown in large pots, where they will be more under control. Careful watering is essential, as these late-growing plants are very subject to mildew.

Hopetoun Gardens, South Queensferry, N.B.

GARDEN FRITILLARIES.

(Continued from page 466.)

Fritillaria latifolia, however, from the Caucasus, is not a difficult plant, and the Dutch florists have raised a large number of fine varieties from it with flowers varying from purple to lilac. They are larger, darker and more fleshy than those of *F. Meleagris*, which they otherwise much resemble. I do not think they are difficult at all, once established, and the few bulbs I have flower regularly enough year by year; but they seem impatient of being moved and so often cause disappointment that I have discarded them from my lists in favour of the forms of our common Fritillary.

F. recurva and American species.—I have left till last the section that indisputably includes the most fascinating and beautiful species. I mean the wonderful American Fritillaries, of which *recurva* and *coccinea* are always so much admired whenever they are shown. But I have been speaking of Fritillaries that we can treat as good hardy perennials in our gardens, and in my own experience most of the American sorts do not come under that heading. Purdy divides them into two sections—one, low-growing plants with leaves clustered about the base and several widely bell-shaped flowers, and the other, taller plants with leafy stems, the leaves in whorls and the flowers bell-shaped in long racemes. The former are the "Mission Bells" of the South Californians, and they are found in sticky black clays which are often very wet in winter. Liliacea, biflora and pluriflora are in cultivation, and if they are less beautiful than the representatives of the next section, they are certainly easier to keep. These others are mainly woodland plants, and their best representatives are the scarlet *recurva* and *coccinea* and the rich yellow *pudica*. I do not think I can add anything useful to what has already been said by others about their culture. In well-drained soil or in pots or pans they are very easily flowered from good bulbs, and the best advice I can give is: Buy the largest bulbs you can each season, pot them up, and enjoy their beauties in the shelter of an alpine-house or cold frame. They are much more beautiful than many annuals with which so much trouble is taken. Purdy warns us that they are not likely to make good perennial plants, for in their own homes they never flower two years running, he says. A new bulb is formed each season on top of the old, and fresh bulbs develop from the rice-like grains round the sides of the old bulb; but energy has to be accumulated for two or more seasons before the prized flower-spikes can be thrust up.

With all the Fritillaries early planting is desirable. Deterioration soon sets in if the bulbs are left long out of the ground. And, at least with the Asia Minor species and those that stand sunshine, it is desirable to have a good percentage of lime in the soil. During active growth all should have ample supplies of water at the roots, and it is for this reason, I think, rather than for the desirability of shade in itself, that so many will do well in a north border in lighter soils which do equally well under a south wall in a more retentive loam.

R. W. WALLACE.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All

reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

TREES AND SHRUBS.

ARBORICULTURE IN GARDENS (H. D. Green-Armistage).—The trees mentioned are usually raised from seeds, excepting Filberts. These are generally raised from suckers. Seedling Walnuts are a long time coming into bearing. It is much better to purchase grafted trees. They come into bearing much sooner and the fruit is more satisfactory. In the case of a grafted tree, there is very little pruning required after it has begun bearing. The Chestnut, as a rule, requires but little pruning, but is quite amenable to the process when this is necessary for the regulation of branches.

PRUNING CEANOTHUS (W. B.).—Your plant of *Ceanothus* growing against a wall should be pruned in February. Cut this year's wood back to within two or three buds of the base. In some cases it may be advisable to remove an old branch, laying in a young one to take its place. When this is done, simply cut the branch back to where it is alive. As a rule, the shoots of the summer-flowering *Ceanothus* die back about halfway. Your Lemon-scented *Verbena* may be cut back fairly hard in February. Cut it back as near the wall as possible. It may be increased by inserting cuttings of half-ripe shoots in sandy soil in a close frame during June, July or early August.

TREES IN EXPOSED POSITION (A. H. Brydon).—You cannot do better than use bands of felt or carpet to prevent the tarred string or wire from injuring the bark of your trees. Tarred string is really better than wire, for in the event of it becoming too tight, it is more likely to be broken by the increase in girth of the trees than wire. If wire becomes too tight, it soon injures the trees seriously. Providing either string or wire is examined once a year, however, it is not likely to cause any serious injury. For windswept positions it is wise to plant short, sturdy trees in preference to those which are tall and slender, for the short ones become acclimatised and able to look after themselves more quickly than the taller trees.

WHEN TO SOW BROOM SEEDS (V. C.).—Seeds of common Broom and Welsh Poppy may be sown at once, or be kept in a cool room and sown in February, according to convenience. The Broom seeds may be sown in pots, pans or boxes in a cold frame, or they may be sown out of doors. Use light, loamy soil and cover the seeds with soil to a depth of about one-sixth of an inch thick. The Poppy seeds may be sown in pots or pans in a frame. Use light, loamy soil containing sand and leaf-mould, and cover the seeds very lightly with fine soil. Place a sheet of glass over the surface of the pot or pan, and water carefully. In both instances the seeds may be sown thinly. As a rule, they germinate without trouble, and the seedlings are soon ready for pricking off thinly in boxes or for placing singly in small pots.

THE GREENHOUSE.

SCENTED-LEAVED PELARGONIUM (Lady C. S.).—You have been rightly informed as to Pretty Polly being the correct name of the scented-leaved *Pelargonium*; but it is not a scarce variety, and can be readily obtained from dealers in this class of plants. Try Messrs. Cannell and Sons of Eynsford, Kent.

BRUGMANSIA NOT FLOWERING (T. H. P.).—A difficult question to answer, for as far as one can judge by your letter, the *Brugmansias* have been correctly treated, and the two old plants at least should have

flowered well. One thing to bear in mind, and which, perhaps, may be the cause of your non-success, is that these plants are liberal feeders; hence they require to be well watered during the growing season with frequent doses of liquid manure. A sunny spot out of doors during the summer should be just the place for them. As their root action is so vigorous, good-sized pots are of course necessary, while the larger they grow the more floriferous are they. You do not say the size of your old plants, but perhaps with the increase of stature they will give satisfaction another year.

GLOXINIAS DISEASED AND PLANT TO NAME (K. K.).—Your *Gloxinias* have been badly attacked by a small microscopic insect, commonly referred to as the Begonia mite, owing to the fact that it was first noticed on this plant. The ravages of the mite have led to a diseased condition of the leaves; hence the brown patches. In the damp atmosphere the decay would be more pronounced than in a drier one. This mite may be kept in check by vaporising with nicotine or dipping the plants in a mixture of Tobacco water and soft soap. As the season, however, is so far advanced, the diseased plants will not flower this year; hence they should be isolated from the healthy ones, and, as soon as the tops die off, the old leaves should be burned. Next year a sharp look-out must be kept for these pests, and at the first sign of any of them the house should be vaporised. The specimen enclosed was far too shrivelled to be sure of its identity, but as you suggest it is a greenhouse climber, we think it is *Maurandia Barclayana*. If so, it will ripen seeds, from which young plants may be raised. The seeds should not be sown until the spring. In future queries a few more details would be a great advantage to us, our object being to make the replies as exact as possible.

FRUIT GARDEN.

LOGANBERRIES: CUTTING OUT OLD CANES (Miss E. M.).—All old canes—those that have fruited this year—should be cut out at once; also the very weak new canes if they would cause overcrowding. Thus the maximum amount of light and air will reach the new canes retained, and they will be well matured by the end of the season.

PEACH PRINCESS OF WALES GOING BAD IN THE CENTRE (F. C. Rogers).—This variety is very subject to this disease, for what reason nobody, as far as we know, can tell. The cavity at the base of the stalk is large in this variety, and is often slightly open to the centre of the fruit. Earwigs soon find this out and penetrate to the centre, and possibly cause the decay.

GRAPES SHANKING (E. F. Fuller).—Shanking in Grapes is often brought about by various causes, such as sour borders, bad condition of the roots of the Vines, and overcropping; in fact, by almost any conditions inimical to the healthy growth of the Vine. In your case we think the roots are at fault. Evidently they are feeble, or your Grapes would have been better developed. The best thing for you to do will be to take away the top soil of the Vine border until a good number of roots are seen, even if you have to take a foot of soil off. Then give the border a top-dressing of the best Vine soil, 6 inches deep, over the roots as far as they extend. The best time to do this will be as soon as the Vine leaves have fallen.

CULTIVATION OF BANANAS (H. E. S.).—The culture of the Banana under glass is not difficult, providing rich soil, a plentiful water supply, a high temperature, moist atmosphere and proper ventilation are available. The best kind to grow indoors is the one grown in the Canary Islands, *Musa Cavendishii*. This rarely exceeds 8 feet in height, while the varieties of *M. sapientum* may exceed that height by 8 feet or 10 feet. Two methods of culture are available, for the plants may either be grown in borders or in tubs or boxes. The best results may be expected from border culture, by reason of the more extended root-run. The bed should be 3 feet deep, at least half of that being above the floor of the house. Beneath the bed, flow and return hot-water pipes should be laid, in order to keep the soil warm. Drains to take away the superfluous moisture must be laid in the bottom of the bed, and over them and all over the bottom of the bed 9 inches of broken bricks, topped with clinkers, should be laid. Over the clinkers lay turves the grass side downwards; then fill up with good, rough, fibrous loam into which leaf-mould, well-decayed manure, coarse sand and half-inch bones have been mixed. When the soil has become warm, plant suckers detached from old plants. Do not overwater before the roots have become really active, after which an abundant supply, warmed to the temperature of the house, will be necessary at all times. Keep the plants well syringed twice a day, and provide a minimum temperature of 65° at night, rising to 75° in the daytime, or higher with sun-heat. Do not crowd with other plants, and when the flowers appear keep the house on the dry side for a week or two, syringing the leaves of the plants but not the flowers. As soon as the fruits are set, feed the plants well with manure-water and give a mulch of manure over the roots. At this time a little extra ventilation may be given, but shading, except of a very light character, is not desirable. Pots, tubs or boxes 2 feet to 2½ feet in diameter and 2 feet deep may be used for single plants, and the same method of cultivation as that already described can be followed, with the exception that more feeding will be required owing to the restricted root-run. Feeding in this case will be necessary long before the flowers appear. Propagation is always effected by means of suckers detached from old plants. The way to succeed with Banana culture is to make sure that the plants shall not receive a check from start to finish.

THE GARDEN.

No. 2237.—VOL. LXXVIII.

OCTOBER 3, 1914.

NOTES OF THE WEEK.

Our Special Rose Number.—Following our usual custom, we shall devote a considerable portion of our next issue to special articles on Roses. These will be written by some of the best authorities on our national flower, and will, we feel sure, prove of considerable interest and usefulness to our readers. The planting season for Roses will shortly be with us, and many will undoubtedly wish to add to their existing collections, and so do all they can to keep their gardens thoroughly up to date. In addition to a number of charming half-tone illustrations, a coloured plate of three superb garden Roses will be included. The price will be one penny, as usual.

Rose Amateur Teyssier.—Although sent out so long ago as 1900, it is seldom that one finds this excellent and charming Rose growing in gardens. The reason for this is difficult to understand. On the recommendation of a rosarian friend, a few years ago we planted some bushes, and few other sorts have been so consistently good. It is moderately vigorous, flowers freely from late June onwards and is rarely attacked by mildew. The blooms are creamy white, with deep yellow centres, and owing to their exquisite shape are excellent for button-holes. The illustration on this page represents a single spray of blooms cut the third week in September. Those who appreciate Roses of this colour should certainly plant Amateur Teyssier.

British Fruit Show Abandoned.—Just as our last issue had gone to press we received a notice from the Royal Horticultural Society stating that the British Fruit Show, arranged to be held on September 29 and 30, had been abandoned. The reason given for this decision was that the military authorities had taken over the society's hall, and that it was impossible to procure another building large enough and suitable for the purpose. At a time such as this, when considerable interest is being taken in all kinds of home-grown produce, it is regrettable that some temporary arrangement could not be made, even if the show had to be on a smaller scale than in past years.

Result of Our Garden Planning Competition.—The work of judging the numerous plans sent in for our competition for planning and planting the little garden is now proceeding, and at the time of going to press is nearing completion. The task has been a very heavy one, but, at the same time, one of considerable interest. We hope to publish the results, with the first-prize designs, in our issue for October 17, when the ideas set forth will be available for adoption by those who are contemplating the laying out

planted more closely than the more robust sorts. It is one of the daintiest white Roses that we know for cutting, and the fragrant blooms last in good condition for some time when placed in water.

A Beautiful Grey and Blue Bed.—One of the most pleasing flower-beds that we have seen for a long time is situated at the lower end of the Broad Walk at Kew, near the lake in front of the Palm House. This is a circular bed, planted thickly with *Ageratum* Princess Pauline, with dot plants, 2½ feet to 3 feet apart, of the grey-leaved *Centaurea candidissima*. The blue flowers of the former harmonise perfectly with the grey leaves, and create an effect that is as pleasing as it is the acme of good taste.

The "Breaking" of Tulips.

A writer in our contemporary *Irish Gardening* for September says that he is very much inclined to think that "breaking" in Tulips is caused by the presence of lime in the soil. We take it that he means when they have been transferred from a soil without lime to one in which there is an adequate quantity. As we believe there is a great deal of trouble in this respect in many places, especially among the Darwins, it would be of both interest and utility to many of our readers if some of those who have suffered in this way would send us a short note for publication, saying if they can trace the "breaking" in their case to this cause.

Collarette Dahlias for Large Beds. Although a good many excellent gardeners do not care for the Collarette Dahlias—single varieties with a

AUTUMN BLOOMS OF ROSE AMATEUR TEYSSIER.

of new gardens or the remodelling of existing ones.

White Rose for the Autumn.—Those who wish for a good bed of white Roses for the autumn should plant Mrs. Herbert Stevens, a Hybrid Tea variety sent out by Messrs. McGredy and Son in 1911. Although rather small, the flowers are wonderfully pure, much more so than those of the better-known Kaiserin Augusta Victoria, and they also possess the additional merit of being held more erect on the stems. As this Rose is only of moderately vigorous habit, it should be

pronounced collarette or ring of projecting florets surrounding the central disc—they are exceedingly showy for bedding purposes, and, owing to their long, erect stems, the blossoms are also excellent for cutting. The following varieties, selected from a large collection a few days ago, are about the best for both purposes: Maidens, bright yellow; Purity, white; Louise, crimson, white collarette; Ailsa, reddish purple, edged white, and white collarette; Holyrood, crimson, edged yellow, and yellow collarette; and Gunfleet, scarlet, and yellow collarette.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Flowers for Wounded Soldiers.—Everyone will doubtless fully sympathise with the sentiment to which expression is given under the above title by Mr. Faudel-Phillips in the issue of *THE GARDEN* for September 19. The appeal to gardeners generally—who are all, of course, as is rightly stated, anxious to render some service at this time—to make contributions in gardening kind to hospitals which have been reserved for the use of our Territorial Forces will probably find ready response among all sections. To this end, and in view of the unfortunate possibility of the necessity for even an increase in the number of hospitals in different parts for the reception of our sick and wounded soldiers before the close of the war, I would venture a suggestion that horticultural societies might lend not inappreciable aid in the direction mentioned by forthwith commencing arrangements for bulb shows, to

deservedly needs all the support possible at this time.—B. W. LEWIS.

A Useful Vase Flower.—*Hunnemannia fumariæfolia*, among its other good qualities, proves to be a most useful vase flower with us, the flowers lasting longer in water than anything else in the hot weather. The plants from which we are now cutting were potted up from the open ground last autumn, and have been kept growing away strongly ever since. They are still full of flower and bud, and look like giving a good supply in a cool greenhouse until late autumn.—F. HERBERT CHAPMAN, *Rye*.

Tomato Fruits Not Colouring.—In many districts Tomatoes have not coloured well during the past summer. Patches of green are to be seen on many specimens, and, of course, this is a defect and lowers their quality either for sale or home consumption. There is an insufficiency of potash in the soil, and if a small quantity be applied, and also some sulphate of ammonia, the fruits will colour splendidly. This treatment will do some good if carried out this year, but it should be particularly borne in mind for next year. The

will be as light and clear as amber. Put them in the pan and let them boil twenty minutes; they never get hard. For Quince jelly the water they were boiled in may be used to make a jelly of the parings. Add 1lb. of white sugar to each pint of juice and boil for half an hour.—ANNE AMATEUR.

Brilliant Montbretias.—Our large cultures of *Montbretia* novelties give rise to many points of interest. For instance, the question of the most brilliant red *Montbretias* comes to mind. Usually the palm for the richest colour is awarded to Lord Nelson, but our observations tend to a different judgment. Three varieties will be mentioned in this note as being specially brilliant—*Volcano*, *Pilot* and *Victory*. The finest of all in colour is undoubtedly *Victory*, a pure scarlet of pretty form, branching habit and exceptional brilliance. The colour is unrelieved save by the yellow eye. It is altogether a most glorious colour. *Volcano* is larger, a fine notable variety, a brilliant orange scarlet, with a crimson suffusion near the centre. It is tall, well branched and of striking appearance. *Pilot* is almost equally good, giving large flowers of a glowing orange scarlet shade. Save for the orange centre, this variety gives a pure self colour, very effective, free and good. All three will prove worthy of attention when known to the *Montbretia*-lover.—P. S. HAYWARD, *Holland House Gardens, Clacton-on-Sea*.

A Little-Known but Useful Climber.—To anyone requiring a rapid-growing and free-flowering climbing plant, I can recommend *Senecio scandens*, a species of recent introduction from China. It is not often met with in many gardens. This has the great advantage of flowering late in the summer and autumn, and, being a rapid-growing and profuse-flowering plant, it should prove a great acquisition to our hardy flowering climbers. A plant on an eastern aspect began flowering about the middle of September last year, and was covered with its small, orange yellow, starry flowers for quite two months. This species should prove extremely useful for the pergola in autumn, when many of the summer-flowering climbers are past and flowers none too plentiful. Probably the most picturesque position of all for this plant would be to allow it to ramble through the branches of any old Apple tree, in the way we too seldom see the beautiful *Polygonum baldschuanicum*.—R. FINDLAY, *The Gardens, Logan, Wigtownshire*.

Ceanothuses in Pots.—A note that appeared early in spring concerning the value of *Ceanothus Gloire de Versailles* when grown in pots was of considerable service in directing attention to its beauty when grown in this way. Though blue flowers are admired by everyone, they are at no time too plentiful, especially among shrubs that flower early in the year. For this reason I favour the employment of some of the early flowering kinds for greenhouse decoration, as they can be had in flower sooner than *C. Gloire de Versailles*. Two good kinds for this purpose are *C. dentatus* and *C. veitchianus*, this last being of a particularly pleasing shade of colour. Even these are not at all amenable to hard forcing, but need to be brought on very gradually. They can, however, be had in flower by the end of April, and at that time their pretty flowers, which are freely borne, are much appreciated. As advised in the case of *C. Gloire de Versailles*, it is very essential that after flowering they are plunged outside in a spot fully exposed to sun and air. An occasional dose of liquid manure is also of great service when they are making their growth.—H. P.

THE NEW ZEALAND FLAX AND NEMESIAS IN MOORAGH PARK, RAMSEY, ISLE OF MAN.
(See page 481.)

be held early in the New Year, the primary object of which should be a distribution of the resultant exhibits among hospitals or convalescent homes. There will, no doubt, be an ample number of channels, too, to which any realised profits might find their way. Or, of course, the opportunity obtains for individuals to render similar service by growing pots of bulbs for distribution. Pots of most kinds of bulbs will last in bloom for about three weeks; hence they make acceptable and much appreciated gifts to all such institutions as those to which reference has been made. Planted now, they can be had in bloom by Christmas and onwards, according to variety. Their easy cultivation, together with their trifling cost, should make such interesting work popular with all who have a desire to show some slight reciprocal feeling towards those who have endured much on our behalf. A further—and, I submit, not unimportant—object which would be served by the practical operation of the foregoing suggestions would be the desirable one of assisting, in some little measure, the nursery trade—a trade which

potash should be applied first, then the sulphate of ammonia. As potash may be scarce next year, cultivators should burn as much garden rubbish, hedge trimmings and wood of various kinds during the autumn and winter, and mix the ashes with the soil.—G. G.

Ripe Tomato Chutney : Mrs. "Busy Bee's" Recipe.—From "Anne Amateur's" manuscript book: Ingredients—7lb. ripe Tomatoes, 1 pint vinegar, 3½lb. sugar, 1oz. Cloves, 1oz. Allspice and 1oz. Cinnamon (whole spices are best). Method—Scald and peel the Tomatoes, drain them well. Boil for five minutes the vinegar, sugar and spices (tied in a muslin bag); then put in the Tomatoes and boil for half an hour. Keep in a stone jar, covered tightly.

Preserved Quinces : A Kentish Farmhouse Recipe.—Ingredients: Quinces, sugar and water. Method: Pare and quarter the fruits, boil in enough water to keep the pieces whole. When they are tender, take them out and to each pound of Quinces add 1lb. of white sugar. Let them stand with the sugar on until the next day, when the syrup

Fasciation in Roses.—In pruning a Rose hedge of mixed varieties in my garden, which I planted about twelve years ago, I found that a stout leading stem of a Crimson Rambler had become fasciated about three feet from the ground, the flattened fasciation increasing in width and becoming more pronounced for another 2 feet or more, where it branched off into five apparently normal healthy stems for another 4 feet or 5 feet. As the whole stem and its offshoots appear strong and vigorous, I am leaving it to see if it will produce any further fasciation next season.—J. R. J.

Hardy Fuchsias.—In many parts, and especially in districts near the sea, hardy Fuchsias form a charming feature during the summer months, and often on into the autumn. There are places, however, where their merits are not recognised to the extent they might be, for even if the plants are cut to the ground during the winter, young shoots are quickly pushed up in the spring. A few leaves scattered over the ground will serve to protect the roots during the winter. The hardiest of all, and withal one of the very best, is *Riccantonii*, which in particularly favourable districts attains almost the dimensions of a small tree. If treated as a herbaceous plant—that is, cut to the ground each season—it will attain a height of 4 feet to 5 feet and flower profusely. Other good old kinds are *coccinea*, *corallina*, *globosa*, *gracilis* and *virgata*. Some distinct varieties raised originally by M. Lemoine of Nancy are *Drame*, *Elysée*, *Enfant Prodigue*, *Florian* and *myrtifolia minor*. The hardiest Fuchsia, with white corolla, is *Mme. Cornellison*, a variety about fifty years old, but still the best for many purposes.—H. P.

Roses with Split Blooms.—Your correspondent "R. F. C." raises an interesting question as to the cause of split or divided blooms in Roses, and suggests there is some definite cause and that great credit will accrue to the discoverer of it. He gives us a list of Roses—W. R. Smith, the two *Cochets*, *Mrs. Edward Mawley* and *Charles Lefebvre*. He might have gone through the whole list of exhibition Roses from *Mildred Grant* to *Bessie Brown*, &c., and included all Roses that have more than an average number of petals, and he would still have been correct in his statement that they seldom give a perfect bloom. So far one can agree with him, but when he goes on to suggest that it is some outside influence at work, such as frost, wind-bruising or twisting and change of temperature, then I must part company with him. I am inclined to think that there is no such cause. Take W. R. Smith, for instance. I suppose 90 per cent. of its flowers "come split," as the Rose-lover has it, and the reason of it is not frost or any outside interference, but simply the "nature of the beast." No amount of protection (under glass if you like), cultivation and high feeding (this latter, as tending to produce more petals, is likely to aggravate the trouble) will alter the fact. Nature cares nothing for our artificial standards as to what is perfect. Her standard, as far as one can form an opinion on it, is something very different; in fact, I do not think I am going too far or saying what is incorrect if I state that left to herself she would never have produced such a monstrosity (to her) as W. R. Smith. The ideal Rose has five petals and numerous stamens; the artificial W. R. Smith has numerous petals (about one hundred and twenty) and few, if any, fertile stamens. If this theory is correct and the normal W. R.

Smith is always divided or split, then he who only wants perfect exhibition blooms should clearly leave it alone. And yet it is a beautiful Rose, fine healthy grower, magnificent foliage; no mildew, no black spot, no rust ever attacks it; and as a standard it makes one of the shapeliest and handsomest of trees. In the young state it is a beautiful bud, ideal for a button-hole. As a hardy Tea it is undoubtedly one of the best of the family, and something of the same sort can be said for all these flowers that "split." It is undoubtedly true that the fewer the number of petals the less likelihood there is of this fault occurring until one reaches the natural Rose, when it is impossible. So I am afraid, "R. F. C.," there is no remedy; in fact, if W. R. Smith could be made never to split, it would not then be W. R. Smith, but a different Rose altogether, worthy to be called after its raiser, lucky man!—HERBERT E. MOLYNEUX, *Southampton*.
